As the pioneering international agreement on telecom services, the FTA constitutes a significant, though limited, achievement in furthering regional economic integration. Although it was possible to build on a comprehensive bilateral private order relationship, fundamental differences with respect to facilities based competition (along with residual sovereignty concerns) meant that agreement had to be focused on enhanced services. This, in turn, requires domestic regulatory responses to implement international commitments to further develop competitive markets.

Viewed optimistically, one might conclude that much has been achieved in the face of fundamental obstacles; viewed less optimistically, one might be struck by how little has been achieved between two countries with such highly integrated telecom systems.

9. Towards the NAFTA

Negotiations are currently underway to expand the FTA to include Mexico in a new North American Free Trade Agreement (NAFTA). It would appear that the FTA's distinction between "basic" and "enhanced" will be maintained. Overall, the development of a new agreement requires that regional free trade concerns be placed in a broader international context; raises for Mexico many of the issues already dealt with in the FTA, and puts a critical searchlight on attempts by Canada to insulate its basic services from bypass to the south.

(a) The GATT Context

Ideally, NAFTA should be viewed as complementary to whatever eventually emerges from the Uruguay Round. Inconsistency must be avoided between regional and global environments. NAFTA should be more focused on specific issues and, as a separate regional agreement, should bind the parties to commitments additional to those negotiated through GATT. To achieve complementarity will require some shift in emphasis from national treatment to genuine market access with greater transparency in regulation.

(b) For Mexico

Appropriate new regulations will have to be developed to ensure that Telmex will not gain an unfair advantage in providing competitive services. Here much may be learned from Canada's experience with the FTA. However, unlike Canada, substantial standards questions will have to be addressed as well.

(c) For Canada

The most provocative question concerns regulatory decisions designed to keep Canada-Canada traffic on the domestic network and to protect Teleglobe's monopoly in overseas traffic. As these protectionist measures involve "basic services", they are valid under the FTA, although of questionable practicability given enforcement realities. However, it is argued that these decisions restrict cross-border access for basic services and also have an adverse overall impact on providers of value-added and information services. In any event, it is said that they limit the ability of service providers in one country to take advantage of lower cost facilities in another country.

As well as the "bypass to the south" issue, long-standing restrictions on the processing of banking data, and the need to yet further liberalize equipment approval procedures, have been raised.

10. Conclusion

It is evident that any discussion as to whether IT developments are more conducive to global developments or regional trading blocs, it will be necessary to keep the FTA (and now NAFTA) in mind to assess limits and opportunities for institutional measures concerning telecom to act as facilitators for regional and international economic integration.

NOTES

MALAYSIAN TELECOMMUNICATIONS
Challenges, Strategic & Policy Issues And Opportunities

Yaacob Arshad, PJK

38, Jalan Sultan Ismail
50250 Kuala Lumpur, Malaysia

ABSTRACT

The last five years was the most rapid phase in the telecommunications evolution in Malaysia. This primarily is due to the privatization of the telecommunications sector that coincided with the rapid economic growth period of the country. The Government's liberal approach has opened doors to a host of new business opportunities and has given rise to many new entrants into the telecommunications arena.

The eighties will be remembered as a decade of remarkable changes in the world of Telecommunications. The changes were the results of new political philosophy at the time when technology was developing rapidly. The pivotal events were the privatizations of the PTTs in various countries, including Malaysia.

The Malaysia experience in telecommunications is worth noting.
Chronologically they are:

1. The first telephone land line in 1874
2. The first telephone exchange was installed in Kuala Lumpur in 1891
3. There were only 21 telephones in Kuala Lumpur supported by some 400 miles of telephone and telegraph lines in 1895
4. The first submarine cable between Singapore (then part of Malaya), Labuan (then part of British North Borneo) and Hong Kong in 1894
5. The first international wireless station operating maritime frequency of 500 kHz in 1926
6. The introduction of Subscriber Trunk Dialling in 1962
7. The laying of SEACOM cable for international telecommunication network in 1964
8. The handing over of international telecommunication services and infrastructures from Cable and Wireless in 1964
9. The first international gateway through Satellite Earth Station in 1970
10. The first International Direct Dialling (IDD) to 4 destinations, i.e. U.K., Hong Kong, Japan and Australia in 1984
11. Modernisation into Stored Programme Control (SPC) in 1980
12. The introduction of data service in 1983
13. The introduction of telefax in 1983
14. The upgrading of International Maritime Service (IMS) in 1983
15. A company Telekom Malaysia was incorporated to take over the operations of Telecommunication Department as part of the Government's Privatization Policy in 1984
16. The Telecommunication Services (Successor Company) Act was enacted in 1985
17. The introduction of cellular radio service (ATUR-Automatic Telephone Using Radio) in 1985
18. The introduction of MARS (Multi-Access Radio System) in 1985
19. The introduction of Maypac in 1988
20. The use of International Business Service in 1988

Malaysia has seen in the last five the most rapid phase in the telecommunications evolution. This primarily is due to the privatization of the telecommunications sector that coincided with the rapid growth period of the country. The PTT in Malaysia was privatized on the 1st of January 1987 and the government retained the regulatory functions under the Department of Telecommunications.

Privatization were merely the appetizer and for more than 4 years, Malaysia has endevoured to develop its own regulatory principles, regulations and practices. The process is still on-going. The liberalization and privatization exercise has raised issues of management of change. Each nation has a different set of values, circumstances and priorities that dictate the nature of the changes and the rate at which they occur. In Malaysia, the Telecommunications Acts sets the framework for the regulation of telecommunications in the country. In the act it confers upon the government the exclusive privilege of establishing, maintaining and working telecommunications in Malaysia. As a corollary to the concept of exclusive privilege, the Minister charged with the responsibility for telecommunications may grant licences to any person.

The authority recognised the need to spell out the future competition policy to take the telecommunications Industry all the way to the year 2020. In charting the future competition policy for basic services they have taken into consideration the following factors:

a) The size of the present network
b) Technologies that are being developed
c) Economies of scale
d) Duplications of resources and networks

The authority has taken a stand that for the basic services, after taking the above factors into consideration, the most viable form of competition would be to use the wireless technologies to compete against the wired network or the existing monopoly.

For the non-basic services, including value added services, the policy will be to promote competition and to remove barriers to market entry in order to increase the variety and quality of services available to the consumers. They feel that these services will promote the formation of the so-called "Information Society" and also provide a competitive edge to the industries.

The question of whether effective competition will take place in a manner that is beneficial to the consumers will depend highly on the policies adopted by the authority. The promotion of a liberalised, competitive environment will certainly speed up the rate of change. The dynamism is an important factor to the national economy and the authority, such as the Regulator is explicitly obliged by law to further develop and improve by creating investment strategies for a future-oriented and efficient telecommunication system. The Malaysian Government has already developed a certain investment incentives to create a conducive atmosphere for telecommunication industry. The incentives, among others, are:

1. Government has accorded priority status to the development of telecommunication sector
2. Encourage local manufacturing for internal use as well as export
3. Flexible equity guideline
4. Government assistance to foreign investors
5. Tax incentives
6. Infrasturcture/utilities: reduced rate of overseas telephone, fax, telex and electricity bill
7. Expatriate personnel: transfer of technology
8. Other key factor included liberal foreign exchange controls and free repatriation of profits, efficient commercial banking facilities, a pool of skilled, cost-efficient and productive labour, economic and political stability, industrial harmony and last but not least quality of life in Malaysia

The Government's liberal approach has opened doors to a host of new business apportunities and has given rise to many new entrants into the telecommunications arena. It has gathered momentum over the last few years and is now a very dynamic industry. The dynamism is expected to accelerate in the near future, astrude with the other developmental activities in the country, to achieve the nation's Vision 2020.

VIEWS

The forces of change and policy response by authority should be considere form the common factors such as:

1. Development of National Telecommunication Policy

They have been a dramatic industrial restructuring; computers and telecommunications are merging. Falling costs due to advances in microelectronics, fibre optics, software and digital technology have driven the technology towards an integrated system such as ISDN. Value Added Network (VANs) are being introduced as evident of divestiture of the monopoly industry.

2. Liberalization or monopoly

It is clear that telecommunication services have grown from the plain old telephone services to new services such as data communications. Basic telephone service so far has been comfortable monopolized by PTT or single government company. With more widespread use of information and data, telecommunications service provider has to contribute huge investment to satisfy this new demand. The reasons are inevitably due to:

- o growth of world trade
- o diversification and specialization of world production
- o partial substitution of goods exports with manufacturing in key markets, as countries try to increase the "local contents" part of goods sold in their market
- o increase in world travel and tourism
- o greater availability of similar services around the world, such as financial, travel and hotel services
- o operations of multinational corporations which increase their international computer communications
- o and so on

Thus the choice of enhancing growth is either harmonizes regulation or liberalization.

3. Standardization and Technical Approval

Standard and technical approval must be available timely as the demand for world-wide user and the uses of newer technology are increasing. The strategy of adoption must be based on world-wide user interfaces and access, transparent transmission and ease of migration.

4. Consumer Premises Terminals

Consumer Premises Terminals (CPT) are contributory to the growth of the telecommunication services. By having an open market down stream fair competition must be observed and the regulatory function by the authority must be exercised to maintain this healthy competition.

5. Value Added Network

Another "grey area" in telecommunication service that need to be addressed clearly. Value Added Network (VAN) must be strategically defind within a known network boundary. The demarcation must be clear between the Public Switching Network and the Value Added Network.

6. Tariffs Structuring

Tariffs structuring must be strategically adjusted to the evolution of the services available. Structure must be available for, as an example:

- o bearer service
- o connection charges
- o subscriber fee
- o administration charges
- 0 utilization charges
- o etc

GLOBAL STRATEGIES : VISIONARY TELECOMMUNICATION APPLICATIONS
THE OLD ORDER CHANGETH
PRIVATE AND PUBLIC SECTOR POLICY DIRECTIONS

Richard E. Butler, A.M.
Former Secretary General, International Telecommunication Union
Victoria, Australia

Digital information processing and telecommunication are driving, indeed forcing change in how business is conducted and how society progresses. Such digitalisation is driving rapidly internationalisation and globalisation which demand more competitive environments and improved economic performance if nations are to enjoy prosperity from this decade.

"What Hath God Wrought" was the message Samuel Morse sent in 1844 from Baltimore to Washington, barely 60 kilometres away. Since that first telegram which was, in reality, the first form of digital application electrically transmitted the marvels of telecommunication have never ceased.

Telegraphy was overtaken by telephony and, until recently, digital transmission by its analogue counterpart. This is all changing, thanks to the progress in electronics initiated a few decades ago by the transistor and advances in semi-conductor technology, wide-band transmission techniques, including laser applications and a host of other breakthroughs which enable the integrated application of technologies; all aided by the convergence of computing and telecommunication processes.

Developments already in train will substantially add further revolutionary changes. ISDN (Integrated Services Digital Network) concepts and IN (Intelligent Network) advances will bring unprecedented opportunities for real-time and integrated system (switching) intelligence applications, as distinct from stand-alone data banks and the like of today. The 1990s will also bring unprecedented mobility and convenience. Users will have the opportunity of trade-offs between processing, assembling, reassembling and transferring information through their stand-alone equipment and chosen centres of operation within the network(s).

This will create significant customer/service supplier partnerships. The customer will become a dominant factor for this decade.

Many of the current differences between private and public (PSTN) networks will also be obliterated in favour of similarity and interaction.

The restriction of the traditional tie to wire line communication between fixed points will be eliminated. Further, progress will evolve in cordless and tetherless apparatus, stations and terminals which will be connected together by high quality wireless local area networks (LANS) and PCN systems. In effect, quality and flexible digital connectivity will be available at low cost through advanced radio communication techniques.

Digitalisation will also bring greater reliability, quality, huge band-width capacities, low cost operation and important economies of scale. Distance becomes largely irrelevant. Coincidental will be the natural flow for end-to-end connection, as telecommunication takes on the shape of integrated software-driven operational functions.

Today's telecommunication systems are, in reality, species of information systems supported by integrated digital technologies. Other adjustments follow.

First, connectivity and networking have put a new-found emphasis on standards for interconnection and harmonisation of actions nationally and internationally. International institutions like the ITU, the ISO and the IEC, as well as the national and regional standardisation bodies, particularly those of the industrialised world are involved with structural adjustments and process reforms.

Digitalisation has provided means to transform dramatically the telegraph and telephone to a sector with major opportunities for improved efficiency and across-the- board economic performance throughout all sectors of the national economies. Significant benefits are available for those who understand and seek to participate in the current waves of internationalisation and globalisation in industry, trade and commerce.

Telecommunication is now increasingly accepted as one of the major pillars for national, regional and global competitiveness and economic performance. Accelerating changes are being forged not merely by technology and innovation, but also as a result of the opportunities for new infrastructures, entrepreneurial service providers and user requirements across all sectors. Avenues are more pluralistic. Choice at affordable prices is increasingly being sought for the wider competitive benefits.

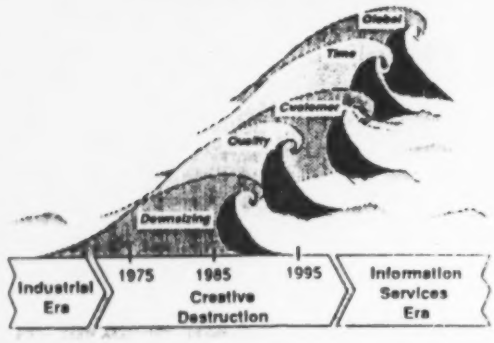
These revolutionary advances are forcing the current waves of globalisation. Organisations are restructuring the way in which they function across the whole spectre of the economy.

Competitiveness is no longer dependent upon where organisations, institutions and persons work, but how they optimise the new found network connectivity; and, in turn, whether they manage knowledge - human and material - effectively.

In the 1990s emphasis will shift from downsizing and cost savings to the servicing of improved quality, customer needs and of shorter time schedules for innovation and service delivery. They are key requirements for successful participation in the growing internationalisation and globalisation (Figure 1).1 The next decade will see the global wave crash over us.

It is interesting to note the alliance or similarity of this evolution with the progress in information technology moving from the data processing DP era (Figure 2).2 It is against this background that organisations will be transformed, and particularly those who wish to survive into the future and share the benefits of internationalisation.

The Next Decade Will See the Global Wave Crash Over Us



We are just entering the frontier in our understanding of this phenomenon

Figure 1

Such revolutionary developments lead naturally to reflection and action on the elements and attributes to be transformed in the movement to a "transformed business" (Figure 3).3 These are the indications of moving from functional hierarchies to networked hierarchies with an emphasis on the knowledge worker and greater flexibility. They change the way multi-nationals function. Greater attention will be paid to local identity, but strapped together in significant information systems dependent upon public and private telecommunication networks enabling strategic alliances.

Collectively, These S-Curves in Organisations Underlie the Economic Transition

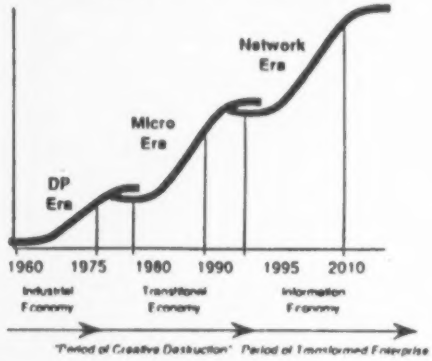


Figure 2

Figure 3

Traditional concepts of vertical hierarchy, control spans and long lines of command will be pushed aside. The movement in conceptual requirements of a global company is poignantly described in Figure 4. The same mindset objectives are equally relevant to those with a domestic and regional aspiration.

Telecommunication is playing a key part in such transformations. It is partnering sectoral support with the necessary financial and transport services5 in an era of growing accent on free trade and services.

Telecommunication processes now provide the opportunity to optimise the full capabilities and role of information systems to serve the visionary global or international mindsets of those who wish to proceed and prosper into the new information services era.

So, having contributed to major adjustments in change in organisations, structures and in user applications, it is inevitable that there will be huge growths in service applications which can only be satisfied effectively by unprecedented growths in telecommunication services.

Thus, the issue is the extent to which individual nations have the will to rise above the self-centred and short term issues and elaborate nationally long-term strategies to optimise the opportunities. It is a question of moving well beyond the generalities of confusing and superficial expressions such as "liberalisation", "deregulation", "privatisation" and "competition", often coupled with asteric phrases which may breed complacency.

The real issues are the provision and utilisation of advances for appropriate productivity, accountability and reasonable competitiveness to participate world wide, optimising the strategic advantages that lie in the current waves of change, assuring the greatest benefits with the least practicable and competitive cost, consistent with national social and economic goals in the broader sense.

Telecommunication policy must have recognition of its multi-dimensional characteristics. Policy must go beyond cost competitive service infrastructures. It must consider all elements of national industry and licensing policy considerations - otherwise the trade and service balances will be decimated.

The words of Alfred Tennyson, a contemporary of Morse, now come well to mind "The old order changeth giving place to new". The many ways in which the poet saw the fulfilment of his world, will surely be true to the telecommunication scene as it moves to the 21st century.

The challenge is to activate adequate will - political and wide ranging but effective visionary mindset policies which encourage the appropriate investments and competitive service infrastructures with necessary freedoms for innovation and technology change with the widest industry objectives. Regulatory intervention should be confined to assisting the process of fair and reasonable competition between the competing service interests.

Electronic Data Interchange (EDI): Environmental Issues and Organizational Considerations

Hyung-Min Michael Chung
Department of Business Analysis and Research
Graduate School of Business
Texas A & M University
College Station, TX 77843-4217
U.S.A.

Electronic Data Interchange (EDI) is inter-organizational exchange of business data in a standard format. Typically EDI provides productivity gains at the operational level of an organization. EDI also bears strategic implications for a company's business. However, benefits of EDI may not be substantial unless EDI is integrated with the company's internal applications and participating parties are in agreement. Eventually, EDI can affect relative relationships between companies, resulting in changes in the industry structure. Principals and agents, and vendors and buyers linked by EDI may expect a new business relationship in the future. This study explores intra- and inter-organizational issues in EDI adoption.

1. Introduction

Ford Motor Company is upgrading its Supplier Online Management System so that 3,000 suppliers will electronically communicate shipping information. Instead of sending information in batch at the end of a shift, notifications will now be transmitted as soon as parts are shipped. "With the batch system, the truck carrying the parts would sometimes arrive before we received the shipping notice," says the Director of Information Systems [Stix, 1985].

"The EDI market... is growing at a staggering rate of 88% annually. The market will leap to $1.9 billion in 1992" [Belitsos, 1988]. "It shows 56 percent average annual growth rate and the user base will jump to more than 22,000 by 1994" [Beckert, Knill & Rohan, 1990].

Electronic Data Interchange (EDI) is the inter-company, computer-to-computer communication in a batch or online mode of standard business transactions. The information is in a standard format agreed upon between trading partners and are transmitted through direct links or by a third-party vendor. The information is transferred electronically so that the need for rekeying by the receiver is eliminated. The transferred information can be integrated seamless with other internal applications. EDI is capable of also communicating non-standard information such as computer-aided design/computer-aided manufacturing (CAD/CAM) graphic documents.

The benefits of EDI that are often cited include reduction in paperwork, errors, lead time, and inventories. However, many of these benefits claimed are based on anecdotal evidence and prescriptive in nature.

"While EDI enthusiasts are quick to point to reports that a full 50 percent of the Fortune 1,000 companies already use EDI in some form, they seldom mention one additional fact: About 90 percent of those users are in the pilot phase (as of 2/89) of setting up EDI systems" [Joyce,

582

1989]. One consulting firm conducted a recent survey of over 500 EDI users showing 65% had EDI connections with fewer than 10 trading partners and 66% were using EDI for less than 10% of business documents [Bradford, 1990].

International paperless trading activity is minimal. The experts on this are the telecommunications networks. Since they make their living moving messages, they should have a good take on what's happening. They report traffic levels ranging between slim and none [Seideman, 1990].

Do little thinking about the potential benefits (of EDI) to them....They tend to see only the expense. For companies with low transaction volume, it can be hard to justify the up-front cost of retraining clerical workers and integrating with their applications. They end up faking it, using a personal computer. Indeed, after receiving EDI documents, suppliers often print them out and distribute them as they have always done [Belitsos, 1988].

A major auto company was at least 18 months behind schedule in implementing its proprietary EDI network [Stix, 1987]. One EDI consultant stated that a client had hoped to have EDI implemented with fifty trading partners at year-end, but instead had connected only two [Joyce, 1989].

These anecdotes also demand us to examine underlying issues that hinder companies from successful application of EDI. In fact, it would be useful to find post-implementation evaluations of EDI by representative companies. Published literature yield little examples of this type of analysis. The lack of this specific information is partly due to its confidential nature. Also, were such information to be published, it would be biased towards a favorable result.

What are real issues in the adoption and application of EDI? How a company can best utilize EDI opportunities to maximize benefits? What are the long term implications of EDI? How do companies adopt EDI? Does EDI affect the intercompany relationships? Environments for EDI adoption may be different for different industries and different applications. Size of the firm, company's familiarity with information technology, market structure may require different perspectives for different cases in the application of EDI.

This study is motivated by these questions and lack of systematic EDI research published. The paper aims at exploring questions such as: What are issues in the application of EDI? What are impacts of EDI? Will EDI affect relationships among companies? Rather than providing the microscopic analysis of a detailed issue, the study offers an opportunity to overview potential concerns related to EDI.

The paper is organized as follows: First, EDI applications and operational gains are introduced. The environmental issues and organizational considerations are described next, followed by a conclusion.

2. EDI Applications and Operational Gains

Opportunities for applying EDI can often be found in companies operating under a large volume of repetitive transactions, a tight operating margin, strong competition requiring productivity improvements, time-sensitive environment, and companies to which EDI implementation have been requested by a large trading partner [Emmelhainz, 1989].

EDI is typically applied to standard business processing such as inventory management, check processing, automatic teller machine, point of sale, electronic fund transfer (EFT), order processing, stock trading, and tax filing. Non-standard engineering CAD/CAM drawings also utilize EDI. CAD/CAM data transactions are bulky, complex, long-lived and expensive to generate while commercial EDI transactions are relatively brief, simple, short-lived and cheap to produce. However, such high cost and longevity of CAD/CAM product data can point to their strategic importance for companies [Shaw, 1990].

Further, the sharing of information (demand schedules, for instance) with suppliers, co-design, and open communications can lead to a long-term, low-cost producer market position. Close ties with customers can be beneficial: An EDI participant is more likely to address customer needs in an effective and prompt manner [Dearing, 1990].

At the operational level, reduced paperwork and clerical effects is a major contribution of EDI. Delays associated with mailing, processing time required for an order entry clerk, buyer, accounts payable clerk, etc. to read and reenter data can be eliminated. Since the data are not repeatedly rekeyed, probabilities for making errors can be lowered. Thus, EDI reduces personnel costs through elimination of redundant rekeying, manual reconciliation, reduced time spent correcting errors, and freeing professional personnel from administrative tasks [Snapp, 1990] [Boudette, 1989]. Since administrative lead time can be reduced, the use of CAD/CAM EDI can expedite the research development cycle for new products.

The speed inherent in EDI can be compared to the common alternative of postal delivery. Even overnight mail cannot be compared with EDI's promise to have messages received within minutes. This increased speed along with its reliability is essential to just-in-time (JIT) inventory systems.

However, benefits come later, may not appear significant until experience is gained in the technology, and might not appear to be very substantial until EDI is integrated with other internal applications. Quite often, start-up costs need to be capitalized to derive the long-term benefits.

3. Environmental Issues and Organizational Considerations

This section explores potential issues related to successful implementation and application of EDI for a company.

In-House Development versus Out-sourcing

Due to the increasing capability and declining cost of EDI software, it may be less advantageous for a company to develop its own software. However, the decision should be based on the nature of applications, in-house resources, maintenance required, and company strategies [American Management Association, 1989].

Standardizing Inter-Company Document Formats

This task is performed within the company by bridging software. Quite often the standards do not specify which code (for instance, seller's catalog number, buyer's part number, etc.) should be used. These decisions are usually left to the trading partners to decide. Before accepting EDI, a company must decide to unify under one standard any incompatible "nomenclature, definitions, and document formats" within the company and attempt to standardize.

Integration with Internal Applications

In implementing EDI, applications at the department and the company levels as well as at the industry level should be considered since it is often likely to under-estimate the time and effort needed to implement EDI with trading partners.

In an EDI system, information has to flow beyond being printed out. For example, it can automatically come from material requirements planning (MRP) systems and be fed into manufacturing systems. These benefits, however, can be the greatest cost of implementing an EDI program. Thus, in many cases, applications may need to be retooled to generate or process EDI data. This process of integration is frequently achieved by a process called mapping. EDI mapping is time-consuming and complicated because multiple databases and trading partners' formats are involved.

Further, integrating the EDI software into the internal data processing system is an important consideration. Revamping the in-house system to allow it to talk to an outside system requires a considerable mental leap.

Inventory Control

Typically EDI is considered resulting in better inventory control, turnover, and reduction of safety stock. However, in some cases suppliers may have to hold more inventory under EDI rather than actually decrease the level of inventory, since expectations of rapid delivery have been raised [Stern & Kaufman, 1985].

Loss of Float on Payments in EFT

EDI involves the loss or decrease of financial float--the time between when an invoice is received and when payment is due. The receipt of prompt payments made possible by EDI through EFT directly benefits the company's true cash flow, reflecting net change in balance sheet accounts having cash inflows and outflows. While the cost effectiveness of EDI may be greater than the amount of money ever earned on float, small companies with limited potential of achieving EDI benefits, and an absence of customer pressure to implement EDI, may be better off scrapping EDI and retaining float [Joyce, 1989] [Medford, 1990].

Control of EDI Processes

As paper documents become obsolete, so do the conventional audit trails. The EDI implementor must be aware that new controls should be designed to assure the integrity of financial data. A control mechanism needs to access multiple application software and routes the transaction to the proper module, sending invoices to accounts payable and payments to accounts receivable [Hill, 1987].

An important control question concerns the consequences of the termination of an established EDI relationship: What costs or security risks may be involved? If a large company has incurred expenses in installing an EDI system with a smaller partner, how would these costs be accounted for if the relationship ends? What about confidential information of the partners once the relationship ends?

User Acceptance of EDI

Non-quantitative feedback is also important. Are employees accepting the new system? Is operation of the new system smooth? Are trading partners making favorable comments about the new system?

Legal issues

Legal aspects of EDI may still be unclear yet. Apparently EDI lacks legislative prescriptions and case law precedents. For example, users may be engaged in EDI without the benefit of signed agreements: What is expected of each party? Who is liable if a transmission fails? Can the interchanges themselves result in legally enforceable contracts?

Security Issues

The data being transmitted are vital business records. This concern has inhibited many companies from using a value added network [Stix, 1985]. Lack of hard copy, authorization and limited access, tracking data, authentication, and encryption should be considered [Sokol, 1989].

Company Relationships in Industry

Since control in trading partner relationships is usually exercised by a large purchasing company over its small suppliers, many large "hub" companies may require their suppliers to be a specific EDI-capable. EDI implementation naturally leads to a reduction in the number of vendors a company does business with, as partners are sought who are also EDI-capable. Between hub

companies and suppliers, EDI investment may turn out to be a switching cost which affects flexibility of a company in changing business partners.

Even if the hub company does not dictate EDI implementation, survival may still be at stake in a competitive industry facing low profit margins. However, the cost of developing EDI systems may not offer strategic flexibility to small companies. Further, the standard issues may also affect the decision flexibility of later participants of EDI.

Timing of the participation in EDI may have different implications for a company's competitive strategies. Eventually, EDI may become a way of doing business and a necessity much like telephone [Benjamin DeLong, & Scott-Morton, 1990]. Thus, what is essential for doing business may not yield a competitive advantage [Clemens & Kimbrough, 1986].

One factor that should not be ignored in making this decision is whether it is believed that a "critical mass" of EDI-participants has been reached, on either an intra-industry, cross-industry, or international basis, that will make implementing EDI worthwhile. Another factor is that economies of scale can be somewhat overcome with EDI. Value of participating in EDI may increase or decrease as the number of participants changes because participants may be able to differentiate themselves being a member of a specific EDI for a certain period of time.

4. Conclusion

Despite considerable excitement on the application of EDI in praise of efficiency gains and strategic implications, there are many issues that need to be discussed about its successful applications. In this study, an attempt is made to identify intra-company, inter-company, and cross industry issues in EDI adoption and applications. Especially, impacts of EDI on the company and the industry are still unclear and need further investigations. The future research aims at testing a variety of aforementioned EDI issues.

Recent Commercial Developments in the New Zealand Marketplace

Grant R Crawshay
Gibraltar Group N.Z. Limited
Auckland, New Zealand

1. ABSTRACT

Telecommunications deregulation has gone hand-in-hand with privatisation. Deregulation has been necessary to enable privatisation to occur. Privatisation has been a means for governments to raise revenue, while making previous monopolies more efficient. There is a fear that new owners may exploit actual or a lack of legislation for their own ends. Deregulation has opened up competitive opportunities for new service providers and equipment vendors in New Zealand.

2. BACKGROUND

In the early 1980's the New Zealand Post Office's ability to operate as an effective monopoly telecommunications network provider was diminishing. Shortages of capital and skilled staff, contradictory objectives and confused management structures severely eroded the efficiency of its telecommunications activities.

On 01 April 1987 Telecom Corporation was established to undertake the telecommunications trading functions of the old Post Office. Regulatory functions including radio spectrum management were transferred to the Ministry of Commerce. An in-depth analysis of the regulatory environment for telecommunications was undertaken by Touche Ross for the Government to establish the viability of competition in a deregulated telecommunications environment. Deregulation began in 1987 with the first area to be deregulated, the provision of building cabling, to be followed shortly thereafter by customer premises equipment (CPE). Full deregulation followed in 1989 with the opportunity for competition in any area of telecommunications.

In September 1990, the sale of the former monopoly, Telecom New Zealand to Bell Atlantic and Ameritech for NZ$4.25 billion was completed.

3. REGULATION

3.1 LEGISLATION

The Commerce Act 1986 - In setting up deregulation the government intended to create an environment which would stress competition in normal business practice, in preference to regulation and state intervention. It is the Commerce Act which ensures that anti-competitive behaviour is not undertaken by a dominant player in the marketplace.

The Fair Trading Act - This Act has no particular reference to telecommunications services, but is intended to govern the day-to-day activities of any trader in the New Zealand market. Particular applications to which it applies, are for example, in the area of misleading advertising.

The Telecommunications Act 1987 - This Act regulates the supply of telecommunications services in New Zealand, and covers a wide range of areas including offensive language and the disturbing use of telephones, monitoring of calls, regulation powers in respect of international services, and information disclosure. It also establishes the powers of network operators, and allows any network operator the right to access land, lay cable, and negotiate with land owners for the same access rights as Telecom received by statute.

The Radio Communications Act 1989 - A system of the tradable property rights for radio spectrum, based on **MANAGEMENT RIGHTS** and **LICENCE RIGHTS**, was introduced in this Act.

3.2 REGULATORY BODIES

Ministry of Commerce - The role of the Ministry of Commerce is to "increase the prosperity of all New Zealanders by promoting a commercial environment which encourages the fair and efficient operation of markets and efficient competitive business".

The Secretary of Commerce can decide standards for radio communications equipment, interference levels for New Zealand, management rights to radio spectrum, and can obtain the relevant Telecom contracts to see that the information disclosure regulations are adhered to. The secretary is also responsible to advise Ministers of the Crown on effective policy, and to ensure that policies are consistent with Governments' overall competition and general policy objectives.

Commerce Commission - The Commerce Commission is an autonomous body set up to enforce the Fair Trading Act. The Commission has the power to obtain from any person, information it believes will establish whether the Commerce Act has been contravened. The Commission can also engage experts to assist in its enquiries.

3.3 FALLBACK OPTIONS

Reregulation - The Government contends that if any two parties competing with each other in

telecommunications cannot reach agreement on particular points, then they should take their differences to the Court where the Commerce Act and general competition law will act as adjudicator.

The back-stop that the Government is quite prepared through intervention to resort to tighter regulation if required. Similarly, the Government is prepared to rescind any part of the present regulatory framework, if it is convinced that the measures put in place are not contributing to the objectives of free competition. It is the Ministry of Commerce, who would advise Government on such matters.

Mediation - Some industry commentators in New Zealand maintain that mediation or arbitration is preferable to regulation. The particular example most often cited is interconnection negotiations between competing carriers. Government has put forward a proposal that all communications should be transparent to the users, and that there should not be any particular barrier to people being able to choose which carrier they wish to use.

4. COMPETITION

4.1 CLEAR COMMUNICATIONS

Clear Communications Limited is a company comprising the shareholders, Bell Canada International, MCI International, Television New Zealand Limited and Todd Corporation of New Zealand. Clear Communications provides long distance (toll) services in competition with Telecom Corporation. The Clear Network uses microwave telecommunications links owned by Broadcast Communications Limited, a subsidiary of Television New Zealand Limited, and it also leases two fibre optic cables from New Zealand Rail Limited between Auckland and Wellington. Further capacity is provided through the lease of fibre optic cable capacity between Wellington and Christchurch from Electricity Corporation of New Zealand Limited.

Clear Communications interconnects with Telecom Corporation at 13 points, enabling users to originate calls to the Clear Communications Network. Approximately 82% of telephones in New Zealand have access to the Clear Communications' services. Clear also provides international services via its interconnect agreement with Telecom, as well as a leased digital service.

Users currently access Clear's national toll service by inserting the digits "050" in front of the national telephone number. Once Clear Communications is able to establish an overall market share of 9% of the national call minutes, then Telecom New Zealand has agreed that they will start negotiating for equal access. It is anticipated that negotiations will commence in early 1992 to give Clear access to the Telecom network without the use of "050".

Interconnect has proved to be a major stumbling block in the connection of new customers to Clear's gateway service. Clear was awarded a contract to provide the Justice Department with a basic telephone service, but due to interconnect problems with Telecom Corporation, the matter was taken by Clear to the High Court. The judge declined an application for an interim injunction, and told the parties to continue negotiations.

Telecom is requiring Clear to dial an access code in addition to a seven digit subscriber number. Furthermore, Telecom wants to charge callers who dial the Clear network a differential tariff at a premium. This will mean that callers would pay a standard Telecom rate plus a surcharge to dial the Clear network.

4.2 BELLSOUTH

Bellsouth was awarded rights to the use of the TACS A spectrum in 1990. Bellsouth is proposing to introduce a new cellular network to New Zealand using GSM technology based on the digital cellular techniques which are currently being introduced in the Pan-European network. The proposed digital system is expected to provide commercial service in Auckland in early 1993 and would compete with the existing Telecom New Zealand analogue cellular network using the AMPS B band.

Bellsouth is currently undertaking interconnection negotiations with Telecom New Zealand, and some difficulty is being experienced regarding the provision of billing and collection services on reasonable contractual terms from Telecom.

At this stage, there are no benefits of competition being derived from cellular services in New Zealand.

4.3 VAN / VAS

A number of new Value Added Network or Value Added Service providers have emerged in New Zealand since deregulation. One of the earlier entries to this market was Netway Communications Limited, a joint venture company formed by Telecom New Zealand and Freightways. Bulk bandwidth is purchased from Telecom New Zealand, and resold through a value addition process. Both data, and voice services are provided by Netway. Through the provision of specialist applications, Netway provides services to customers which are largely non-competitive with Telecom New Zealand's services.

A number of smaller niche market suppliers have also sprung up, but these offer limited competition to Telecom, because they are reliant on the provision of bulk bandwidth by Telecom.

4.4 EQUIPMENT RESELLERS

existence."

The rather robust form of legislation has proved so far to be more of a damp squib. It is not surprising that Clear is doing everything it can possibly think of to maximise its distance from Telecom. (10)

Litigation is currently under way in New Zealand on the following cases relating to telecommunications:

- The Commerce Commission investigation of allegations of overcharging on Telecom's megaplan (high speed digital transmission). services now under investigation for more than two years.
- Telecom's appeal to disallow its purchase of the AMPS A radio spectrum, one year since licence rights were awarded to Telecom.
- Various cases relating to interconnection with Telecom's services brought by Clear Communications, and Bellsouth. These vary from the assignment of specific access codes for interconnect, and exchange codes for the provision of Centrex services.

There are also several cases of a lesser nature where Telecom has taken action out against other parties for the use of unfair practises.

8.5 VENTURE PARTNERS

For new entrants wishing to join forces with parties who already have an existing telecommunications infrastructure, the opportunities are limited. Although parties like Clear Communications has established relationships with Broadcast Communications Limited (BCL), New Zealand Rail Limited, or Electrocorp, where the business of a new entrant would be non-competitive with Clear Communications, there is no reason why some arrangement could not be made. George Newton, the CEO of Clear Communications is on record as saying they would entertain "a strategic alliance with somebody who has already taken the risk" (9) in order to get into the cellular mobile business.

There are of course opportunities for new entrants to enter into relationships with both Clear Communications and Telecom New Zealand.

8.6 LOCAL SUPPOR

It is cost effective for any organisation contemplating setting up telecommunications operations in New Zealand to take advantage of local support. This could range from the initial business or marketing studies, applications for licences, identification of venture partners, liaison with Ministers / Ministry of Commerce / Commerce Commission / Telecom New Zealand / Clear Communications etc, arranging local finance, public relations, monitoring of market trends and changes, recruiting of personnel and training of expatriates.

Local knowledge on the customs, market, political structure, and the availability of other resources in New Zealand can be particularly beneficial to a new organisation.

With the downsizing of Telecom New Zealand, there is now a surplus of qualified telecommunications engineers and technicians in New Zealand. These people have proven to be particularly adaptable in taking on the challenges required to establish new telecommunication ventures. Given the right level of management supervision, this is often the most cost effective way of installing new telecommunications systems.

9 WORLD TELECOMMUNICATIONS LABORATORY

9.1 OBJECTIVES

The New Zealand Government has considered the opportunities for New Zealand to do more than just wait for international developments in communications technology. The concept that the Government is exploring is:

"New Zealand becoming an international centre of excellence in information technologies and interactive communications, thereby enhancing economic advantage and international competitiveness." (11)

The Government has asked a number of officials including the Chief Scientist of the Ministry of Research, Science and Technology, to prepare a study into the world communications laboratory concept to address the following questions:

- how can the WTL concept best be aligned with other government initiatives?
- what use of advanced communications and information is already occurring in New Zealand?
- what new communications and information technologies are becoming available which the New Zealand Government and private organisations can exploit?
- what obstacles or costs are there which might limit the introduction of these technologies?
- what areas of policy or regulatory issues need to be considered covering access to, and availability of, information which may be relevant to the successful realisation of the WTL concept?
- what role might government usefully play in promoting further exploitation of opportunities?

9.2 NEW ZEALAND'S UNIQUE POSITION

It has been previously commented that the relatively small size of the total New Zealand market may be regarded as a discouragement to investment. However, this small market may actually be one of the attractions for companies wishing to trial applications. The basic concept is not new, as there are analogies with the "First Cities" project being sponsored by Kodak, Corning, Bellcore Laboratories, Paramount, Apple

opportunities available in New Zealand, for example in directory services, or particularly in the provision of value added services.

It is perhaps the information area which will have the greatest impact on telecommunications in New Zealand. Electronic data interchange (EDI) has long been vaunted as one of the major advances of the information age. Although overseas experience is mixed, in New Zealand, the Department of Customs and private sector customs brokers have already developed an EDI system to facilitate the processing of imports and exports. The system reduces the time for processing imports from 5 days to 4 hours. In some cases, goods can be cleared through Customs before they have even left their source country. The EDI system could cut almost 2 billion dollars from the cost of New Zealand's imports and exports, and remove a substantial disincentive to foreign trade (5).

Other possible opportunities exist for the provision of information services in New Zealand. In the United States, newspaper publishers are fighting a move that would see the 7 former Bell system companies establish an advantage over newspapers and other information providers by using their telecommunications networks to transport information.

Peter Troughton, Telecom New Zealand's Managing Director, believes New Zealand has the potential to take strong advantage of the burgeoning international consumption of software. Software consumption, Troughton says, quadruples every year a trend likely to continue for the foreseeable future. Suggesting that New Zealanders have just the right characteristics to make them outstandingly efficient and effective software developers, Troughton states that New Zealand could become "The Software Factory of the World". New Zealanders, he says, are renowned for their creative problem solving ability, innovative thinking, versatility and their general competence, characterised by their ubiquitous "do it yourself" approach (6).

Indeed, TSSC, (a Telecom subsidiary company) has been operating in the area of software development for the NEC NEAX exchanges for some six years with a high degree of success.

8.2 DOMINANCE

Some commentators have considered the dominant position of Telecom and the relatively small size of the market mean that the full benefits of deregulation, which would apply in larger markets with more diverse market participants, will not be experienced in New Zealand.

Although New Zealand is a small and relatively isolated market, its ties with Australia through Closer Economic Relations (CER) offers the investor in New Zealand a springboard to Australia. There is currently a harmonisation of business regulation between Australia and New Zealand, and many Corporations are aligning market strategies for both Australia and New Zealand. There are however still significant differences in the telecommunication regulation between the two countries.

Several issues are currently being tested in the courts in New Zealand. Telecom's rivals are keen to access the 1.5 million names and addresses provided to Telecom for telecommunication services. This would allow Telecom subscribers to use Telecom's rival services without having to explicitly apply for them. In addition, controversy over the ownership of the national numbering plan abounds. The Ministry of Commerce has sought comments and submissions from interested parties on the numbering plan to ensure that a more coordinated approach to numbering is established, to foster competition. These submissions closed on 10 December 1991. The outcome of the investigation is still awaited. The report concluded that Telecom owns the National numbering plan but does not have the right to allocate all the numbers, and that Telecom had bought the right to its own telephone numbers when it established the State Owned Enterprise in 1987. However, Telecom does not have the right to allocate numbers to competitors, and if there was evidence that competition was blocked or severely diminished by numbering issues, the Government could legislate on the issue.

Other matters of dominance are fully addressed by the Commerce Act and the Fair Trading Practices Act.

It is no secret that both Telecom and Clear have spent substantial sums of money on legal issues, $100,000 spent by Telecom relating to local loop problems alone (7), and Clear Communications state they would be that looking at close to six figures (8).

8.3 REGULATION

Many of the questions relating to regulation revolve around the question of dominance. Presently many of these regulations are under test in the Court. As "regulator" of the "deregulated" telecommunications industry, the Government hovers in the background, ready to intervene only if necessary (9).

8.4 LITIGATION

John Crook, advisor to Telecom Managing Director, Peter Troughton in the September edition of the North American Telecommunications magazine TEM, stated "there is no regulatory agency in New Zealand making up rules about who can connect and who can do what, and what lines of business we can be in or not, although we do have a rather robust form of anti-trust legislation, which stops dominant companies from using their position to crush the competition out of

prices by more than the increase in the consumers price index. Telecom is concerned about market share erosion being caused by Clear, and they are claiming that the profit of the Regional Operating Companies is being unreasonably affected. There is a case under the kiwi share to raise standard residential charges above the consumer price index figure if Telecom can demonstrate that their profit has been unreasonably affected. At this stage there has been no decision to approach the Government on these grounds.

Telecom maintains that cross subsidisation still exists to the Telecom local loop, and estimates this to be $250 - $300 million per year. Although it could be maintained that in the sale of Telecom the new owners should have made provision for the level of cross subsidisation, Clear have made it known that they are not averse to contributing towards this cross-subsidisation.

Clear's pricing of leased circuit charges are typically 10% below the advertised rates of Telecom. During the last three years there has been a 50% reduction in the leased circuit charges by Telecom, made up in a variety of ways.

Telecom is also offering customers a "Memorandum of Agreement." Under these agreements, customers are offered a discount from 6 - 9% of their total Telecom charges, providing they sign up for a minimum period of time, typically 3 - 5 years. The discounts generally vary with the size of expenditure, and the period of time for which the customer is willing to sign up. The Agreement also expects the customer to make every endeavour to increase their telecommunications expenditure with Telecom by 10% per annum, and to give Telecom the status of preferred supplier. There are also "claw-back" provisions in the Agreement, whereby customers withdrawing from the Agreement during its tenor, must refund discounts received to Telecom.

For customers who are renting equipment, and who are major national and international toll uses, as well as heavy users of Telecom's data networks, the Memorandum of Agreement may be particularly attractive. Some customers have signed the Agreement for a period of ten years.

7.3 STANDARD OF SERVICE

Since the corporatisation of Telecom New Zealand, the standard of service provided to customers has steadily increased. However, this has not been without some cost increase. For example, Telecom New Zealand no longer provides 24 hour fault clearance. Both businesses and residential users must pay additionally for the clearance of faults outside normal working hours.

Clear Communications on the other hand has adopted a policy of 24 hour service. In line with their intention to provide a clear differentiation on the basis of service much emphasis has been placed on this aspect. Business customers are reporting that the level of responsiveness of Clear compared to Telecom is significantly better.

8. BARRIERS TO COMPETITION

8.1. OPPORTUNITY

New Zealand is an extremely small market by world standards. It has a population of approximately 3.3 million people, with 1/3 of that population being in the Auckland region. The South Island is the less densely populated with fewer people than the Auckland region. However, New Zealand's population is upwardly mobile, and New Zealanders are traditionally particularly eager to uptake new technology.

New Zealand is a narrow thin country and lends itself particulary well to services being supported from a central back-bone network, with a number of short spurs emanating from it. Apart from the dominant telecommunications provider, Telecom New Zealand, there are a number of other organisations which have set up their own networks, for example in the areas of television, power reticulation, and railways. However, the new network service provider, Clear Communications, has already taken advantage of these players.

The absence of regulation in New Zealand means that there are few rules by which new entrants must play. Those rules that do exist really relate to the prevention of anti-competitive practices, or certain ground rules relating to the issue of licences, for example for radio spectrum.

There are few mandatory requirements to be met before an organisation or individual can set up as a network provider. There is no statutory right given to Telecom to be the exclusive provider of services, and neither is there a limit to the number of people who can be granted "network provider" status.

One of the next areas of opportunity in New Zealand for new entrants will be competition in the cellular market. The New Zealand market is already strongly competitive at dealer and network pricing level, with 200 dealers nationwide offering a range of equipment and services. Cellular service is not yet regarded as an essential business tool. The potential customer either chooses to subscribe or do without. New Zealand is one of the cheaper networks in the world to subscribe to, but the cost of service is still a prime consideration for customers. International experience has demonstrated that where cellular network competition exists, the greatest impact is the movement of customers between networks. This is service, not cost based.

There will also be a number of niche

business is by paying full commercial rates to Telecom for access to its international services. This has forced Clear to make a decision to go their own way by buying a stake in the Tasman 2 cable, signing a contract to have a satellite dish built, and to enter into negotiations with Intelsat for overseas access. By the end of the first quarter of 1992, Clear anticipates being a fully fledged international provider.

As over 50% of the international traffic is between Australia and New Zealand, Clear will be interested in dealing directly with Australian parties such as OTC. Clear will doubtless seek a correspondent in the United States.

6.4 CELLULAR

The only licence currently awarded is to Bellsouth for the provision of cellular services using the TACS A band. The award of a second licence in the AMPS A band, is being challenged by Telecom in the High Court. At this stage it is unclear as to whom the AMPS A licence will be awarded, and there is no indication whether a third competing cellular service will be set up or not.

Bellsouth is currently undergoing negotiations for interconnect with Telecom, and have placed advertisements for staff to establishment the New Zealand operation. Commercial operation is proposed for 1993.

In the meantime, Telecom Cellular Limited is enjoying a monopoly, and is continuing to sign up new subscribers at a rate almost unprecedented in the cellular world.

There are now in excess of 60,000 cellular users in New Zealand, and market analysts suggest that there is a medium market size of between 330,000 and 500,000 mobile users in New Zealand.

7. IS COMPETITION WORKING?

7.1 USER ACCEPTANCE

In New Zealand, telecommunications has been treated as an expensive utility. For as long as users could remember, the New Zealand Post Office or lately Telecom, was the only source of telecommunications services. This resulted in telecommunications not being considered as a strategic business tool. Responsibility for telecommunications expenditure often was placed in an administrative section of a company.

Customer's, now faced with a wider range of services, are now able to exercise their powers, and ensure that telecommunication systems are chosen which not only best meet their needs, but also are able to be operated the most cost effectively. Chief Executive's are now able to make the choice on whether they manage their own operations, and they are becoming increasingly accountable to their boards in terms of cost effectiveness. This choice will grow as competition increases.

In 1970, Peter Drucker wrote that, "one of the most potentially earth shaking forces in our economy is the technology of information." (2). It has taken 20 years before the economic benefits of technology have really been able to be harnessed in New Zealand.

According to HS Dordick "...information technology and the more efficient use of information can enhance economic growth by:

- increasing labour productivity,
- increasing market reach and penetration for products and services,
- creating higher valued products and services,
- creating customised products and services for specialised markets,
- in reducing management and coordination costs" (3).

A much publicised report which has become known as "the Porter Project" in New Zealand, analyses current economic status and development options in New Zealand. This emphasises the competitive advantage brought about through the efficient use of information.

"Many New Zealand firms simply need to raise the level of their game in order to compete effectively in international markets. The need is to develop a clearer understanding of the structure of the industry, the needs of their customers, and the strategies and strengths of their competitors. This knowledge in perspective is essential to the formation of effective strategies" (4).

As with most information technology applications, user acceptance of these benefits is coming slowly. The concept of the "world telecommunications laboratory" (refer section 9) is intended to increase user awareness of the benefits of using telecommunications as a strategic weapon.

7.2 PRICING

The deregulation of the CPE market has reduced the purchase price of equipment in real terms as much as 50%. In the national tolls area business hours costs have been reduced for two principle reasons. The first is due to the progressive removal of cross-subsidies from toll use to domestic use and the second is as a result of competition. It is estimated the since deregulation, in three years a total of $350 million has been returned to business users in the form of cross-subsidy removals or price reduction due to discounting. Both Telecom and Clear are offering discounts of up to 15-20% for business users.

As part of the "kiwi share" undertakings made to the Government at the time of the Telecom sale in September 1990, Telecom undertook not to raise

Competition in the area of customer premises equipment (CPE) was one of the first areas to be deregulated in New Zealand in 1987. Deregulation offered equipment vendors the opportunity to sell their products directly to the user. All the major PABX vendors, and more recently a new wave of voice mail, call detail processor, and cable / systems installation companies have provided competition.

This area to date has probably one of the most beneficial areas of deregulation in New Zealand. Competition is fierce, with prices and service being extremely keen. There is a major shakeout occurring presently within the industry, with the belief that there are too many PABX vendors in a market the size of New Zealand.

5. USER / LOBBY GROUPS

5.1 TUANZ

The Telecommunications User Association of New Zealand (TUANZ) was formed as a nonprofit incorporated society in February 1986, in anticipation of the enormous changes through deregulation.

The aims of the organisations are to foster an understanding of the changes during regulation and how to manage them, to provide a forum for discussion of pertainent issues, and to represent users requirements and view points to government and to telecommunication suppliers. Government sees TUANZ as an important contributor to policy debates (1).

5.2 ITANZ

The Information Technology Association of New Zealand (ITANZ) was formed at about the same time as TUANZ, and has similar objectives. However, it concentrates primarily on Information Technology matters, and is more of a user group.

5.3 PRIVATE LOBBYISTS

The use of private lobbyists in New Zealand to influence telecommunications policy and decision making, is not particularly widespread.

6 WHERE ARE THE BATTLES BEING FOUGHT?

6.1 GENERAL PERCEPTIONS

Casual telecommunications observers would be lead to believe that the telecommunications battles are taking place in the area of toll bypass. In relation to the difficulties being experienced between emergent network providers and the dominant carrier, this perception can be understood. However, although the upwards spiral of toll price rises has been halted, and in real terms costs have reduced since the corporatisation of Telecom, real competition is taking place at a level which has not seen major benefits to business users.

A price war commenced in late 1991 between Clear and Telecom with the discounting of weekend toll services. Although much television and media advertising surrounded this very open example of competition, revenue volumes associated with this segment of the market are in fact insignificant. The discounting offered by both parties during the weekend, did little to bring down business costs. The actual impact on both party's revenue streams, due to the discounting was very small.

6.2 CPE

Competition in the Customers Premises equipment area has been fierce since soon after deregulation. Telecom's market share in the area of major PABX sales has been challenged by 3 major PABX vendors, Ericsson, GPT, and Philips. Telecom has reverted from renting or leasing their equipment, to offering it for direct purchase. The combined effect is that the real costs of providing PABX services to businesses has reduced. Users also have the opportunity to bring the management of many of their PABX functions in house, with attendant cost savings.

Intense competition has resulted from suppliers sharpening their pencils or improving their level of service, in an endeavour to sustain or gain market share. Technology advancement of systems have ensured that there is a ready market for new PABX systems.

In other areas, for example cable installation and data communications, a number of smaller organisations have sprung up to provide a fast and cost efficient alternative to Telecom. Through the efficiency gains due to restructuring of Telecom Corporation, and the competition brought about by the deregulation of CPE, users have seen waiting times for the installation of cabling and PABX systems reduce from in excess of one year, to weeks or months. Prices have also tumbled as a result of efficiency improvements, and intense competition.

6.3 TOLL BYPASS

Clear Communications has been the true pioneer of toll bypass in New Zealand. In entering the New Zealand telecommunications market, Clear Communications was able to take advantage of the few existing telecommunications infrastructures. Through the introduction of telephone exchanges at Auckland, Wellington and Christchurch, Clear Communications has been able to establish relatively quickly, and at a cost of some $140 million dollars, a network which has been able to challenge Telecom.

The true battle will be fought on the toll front when Clear Communications is able to achieve in excess of the 9% of national minutes required to begin negotiations for equal access to the Telecom network.

At present Clear's only access to international

Computers and others in the USA.

There is tremendous support for the concept of the WTL from organisations such as the National Library of New Zealand, the Institute of Policy Studies, and various government departments such as Treasury and Valuation. Within the Ministry of Research, Science and Technology, careful consideration has been given to the future, particularly with regard to enabling technologies, or core competencies which will be especially relevant to the maintenance and future growth of New Zealand's economy.

There are a number of new forms of products and services which can be produced and effectively exported by New Zealand. Dr. Ian Forrester of the Ministry has identified that "these new products are increasingly knowledge based or value added - like specialty food products, yacht designs, quality clothing, leisure facilities, or software programmes for computers" (12).

9.3 OPPORTUNITIES

The particular opportunities offered by the World Telecommunications Laboratory include imaging systems, applications for health, meat processing, banking, legal services, accounting, town planning, architecture, libraries, building, and tourism together with the provision of business and consumer access to information based services, the production of value added telecommunication products, and software development.

10. KEY ISSUES

The key issues which have evolved through deregulation and the emergence of competition in New Zealand can be briefly summarised as the following:

Interconnection - The ability of new entrants to gain transparent access to the existing telecommunications network in New Zealand has proved to be probably the biggest significant aspect in the introduction of competition in New Zealand.

Numbering plan - The numbering plan is a key ingredient to allow equal access of customers to any competing network.

Customer Information - If new competitors are able to have access to the 1.5 million names and addresses provided to Telecom for telecommunications services, this would allow customers to use competitive services without having to explicitly apply for them.

Cross-Subsidies - The extent of toll service subsidies to domestic services has yet to be properly ascertained. Telecom argues that competitors should help bear the cost of these subsidies, while competitors say that this is merely a device to impose extra costs on competitors.

International Access - Telecom is currently the signatory to INTELSAT. One option is to allow major New Zealand users to have direct access to INTELSAT. The calculation of international accounting rates is also under debate with countries with low collection rates claiming they are disadvantaged.

Light / Heavy Handed Regulation - The various players in the deregulated market are arguing variously for light or heavy handed regulation. Other opportunities are for an arbitration or mediation role to be played by the government, or a government appointed body. The need to revert to a relatively expensive and time consuming option of using the courts to resolve these disputes may needlessly draw out the time in which a satisfactory solution can be achieved.

2. The accounting rate established by international carriers purports to compensate for half of the international haul and the associated gateway and domestic circuits needed to originate or terminate a call. Over time, accounting rates have failed to trend downward as technological innovation accrues lower per unit costs. An imbalance in the flow of traffic magnifies artificially high accounting rates to a carrier's financial benefit or detriment depending on the volume of international traffic it generates.

This paper will explain how the settlement process works, and will identify how users and carriers have avoided accounting rate liability through creative routing arrangements despite an FCC policy that requires a uniform accounting rate for parallel routings. In view of the high stakes involved, the paper will consider what options exist for reducing United States international carrier settlement deficits without unilateral and heavy handed regulatory intervention.

3. Introduction

International telecommunications involves a voluntary "operating agreement" established between "foreign correspondents" who match half-circuits or other types of ownership units in transmission capacity. This bilateral arrangement anticipates a complete routing arrangement from caller to the intended call recipient, including the domestic "tail" circuits running to and from an international gateway facility, a satellite earth station or point where a submarine cable accesses domestic networks.

Routing arrangements and traffic volumes predictably have an impact on the terms, conditions and compensation for terminating or originating international traffic. In theory, the negotiated "accounting rate" represents the approximate cost incurred by each foreign correspondent to handle half of the international route, and all necessary domestic routing.

If the two carriers have equal traffic volumes, then they do not have to "settle accounts" and transfer funds from the toll revenues collected. However, for most telephone service routes between the United States and foreign countries [1] four factors work to generate what in 1988 amounted to a $2 billion outpayment by United States International Service Carriers ("USISCs") [2] to their foreign correspondents:

(1) United States outbound traffic volumes, greatly exceed the return, inbound flow, in part the product of rate reductions;

(2) Foreign international telecommunications rates significantly exceed what USISCs charge, thereby retarding demand;

(3) Most current accounting rates substantially exceed the actual cost of providing service, despite technological innovations that have reduced the cost of providing service; and

(4) USISCs, without apparent financial penalty, have shifted onto ratepayers the consequences of artificially high accounting rates.

A 1988 Report of the Federal Communications Commission's Common Carrier Bureau reached the conclusion that the growing accounting rate deficit partially results from the fact that USISCs charge rates to endusers substantially below what their foreign correspondents charge for the same route. [3] Given an imbalance in traffic flows, some imbalance in payments will ensue. But the Common Carrier Bureau poses the essential question "as to how much of the U.S. balance of payments deficit for telephone service is attributable to the underlying traffic flows and how much is attributable to accounting rates that are above costs." [4]

The Bureau concluded that approximately half of the deficit represents a subsidy from United States ratepayers. [5] In August, 1990, the Federal Communications Commission proposed an activist regulatory posture to encourage USISCs and their sovereign foreign counterparts to reduce accounting rates and the annual $1 billion "direct underwriting by U.S. consumers of foreign telecommunications administrations." [6]

This paper will examine the FCC's latest accounting rates initiative and its International Settlements Policy ("ISP") [7] that seeks to prevent foreign carrier tactics that exacerbate the USISC settlement deficits. The paper will explain how international carriers exploit artificially high accounting rates, while avoiding them when such rates reduce their settlement windfalls. In view of the mounting USISC accounting rate deficits, the paper will also assess the efficacy of the Commission's policy requiring adherence to a single accounting rate per route by all USISCs providing functionally equivalent service.

4. Outline of the Problem

Despite a clearly articulated preference for avoiding marketplace intervention and oversight, the FCC remains keenly interested in the accounting rate settlement process. Such sensitivity stems from the fact that in most instances, a number of USISCs must attempt to secure an operating agreement and settle accounts with a single foreign carrier.

So long as the foreign carrier has one foreign agreement, typically with AT&T, it has access to all United States destinations. Unless additional USISCs can convince the foreign carrier that additional traffic volumes will compensate for the additional costs incurred to interconnect with them, the foreign carrier has little incentive to confer additional operating agreements.

The FCC infers that foreign carriers possess both the incentive and capability to leverage their superior bargaining position by "whipsawing" one USISC against the other: "Generally this has involved a PTT seeking a modification of an accounting rate in a manner more favorable to the PTT--that is, a reduction in the rate paid by the PTT to the U.S. carrier for delivery of traffic in the U.S. or an increase in the rate paid by the U.S. carriers the PTT for delivery of traffic in that foreign country." [8]

The FCC's ISP generally requires all USISCs "offering similar service to the same foreign point [to] do so under identical accounting rates, settlement rates and divisions of tolls." [9] "Specifically, . . . [the Commission] required that operating agreements stipulate uniform accounting rates (the negotiated rate of reimbursement for service, which is shared by the initiating and terminating entities); uniform terms for the sharing of tolls (the percentage of the accounting rate to be allowed each entity--generally for direct traffic, 50-50); and uniform settlement rates (the currency conversion rate used to arrive at the currency stipulated in the operating agreement, usually gold francs (GF), U.S. dollars, or special drawing rights (SDRs))." [10]

The FCC imposed uniformity in accounting rate settlements for each route and for each service, so that no foreign carrier could seize the upper hand in revenue division negotiations and secure revenue concessions by playing one U.S. carrier against the other. [11] Without a regulatory mandate of accounting rate uniformity, the Commission theorizes that foreign carriers could in effect auction off inbound United States traffic flows to the highest bidder, i.e., the USISC willing to part with the greatest share of the toll revenues.

In application, the Commission's ISP appears to have mandated uniformity of accounting rates uniformly stuck at artificially high levels, far exceeding actual service costs. Because the ISP requires uniformity, it appears that USISCs have little incentive to press foreign correspondents for lower accounting rates. The initiating carrier would risk good corporate relations with the foreign carrier whose officers may have great leeway in determining how to route return, inbound United States traffic. The FCC's uniform accounting rate policy would mean that all other USISCs would benefit from the single carrier's initiative, probably without any adverse relational consequences.

5. Philosophy of the FCC's Policy on Accounting Rates

Routing international telecommunications traffic involves the joint venture of two or more carriers who agree to "match half-circuits" linking nations. Such participation requires collaboration in the form of consortia for joint ownership, operation and maintenance of international transmission facilities like transoceanic cables, and international cooperatives like the International Telecommunications Satellite Organization ("INTELSAT"). Typically, international facilities are collectively owned, with ownership interests allocated as a function of investment made by individual carriers.

In recognition of the coordination necessary to achieve international links, carriers enter into arrangements that establish the terms and conditions for providing service between two nations. A separate arrangement usually is negotiated for each type of service between each pair of nations. A key component to international traffic routing is the financial terms and conditions under which one carrier compensates the other carrier for agreeing to match international circuits and provide the switching and routing, including the domestic facilities, necessary to deliver calls to the intended recipient.

The accounting rate serves as the basis for dividing toll revenues between carriers jointly providing an international service. [12] It is designed to reflect the fact that both carriers incur costs in making an international service available, and that such costs should be shared equally. Accounting rates are negotiated by the participating carriers and have two components:

> 1) the unit of currency used and the applicable rate per unit of traffic, e.g. 1.34 International Monetary Fund Special Drawing Rights per minute of international message telephone service traffic is shared between USISCs and Japanese international carriers; and
>
> 2) how the accounting rate amount will be split between correspondents, usually 50/50.

Accounting rates purport to reflect the total cost generally incurred by all carriers to achieve a complete international routing, i.e., both international half-circuits and both domestic tail circuits to and from the international gateway via domestic facilities. However, FCC analysis clearly shows that "accounting rates for international telephone service ("IMTS") [13] are significantly greater than the costs of providing service." [14]

Disparity between accounting rates and actual routing costs would have little significance if the traffic volumes generated to and from the United States were roughly equivalent: there would be no major transfer of payments between carriers. Accounting rates have great significance when an imbalance of traffic streams exists as is the case for IMTS between the United States and many foreign nations. Significant tariff rate reductions in the United States has stimulated outbound IMTS calling resulting in traffic volumes far in excess of inbound U.S. flows.

Typically, the collection rates for IMTS in foreign nations, the amount endusers pay per unit of consumption, vastly exceed carrier cost and the equivalent outbound United States rate, with the result of dampening demand for inbound U.S. calling. Because USISCs generate significantly more traffic for their foreign correspondents to terminate, than the inbound, return flow, USISCs must transfer a greater amount of revenues than they receive in the settlement process.

High accounting rates mean that a net debtor nation must pay an even greater amount in net settlement payments for the disparity in traffic volumes. Despite reductions in the per unit cost of international telecommunications, accounting rates have not dropped significantly. It appears that despite increasing outpayments, USISCs have been less than vigorous in their advocacy for accounting rate reductions. While such high accounting rates do not necessarily reflect foreign carrier whipsawing of USISCs, it represents a surcharge to United States ratepayers and falsely prevents USISCs from lowering rates.

Perhaps USISC reluctance to press for lower accounting rates stems from concern that such advocacy might prompt PTT retaliation in ways that further hurt profitability. But the FCC's Common Carrier Bureau implies other reasons:

(1) international calling volumes are rapidly growing, and despite the massive outpayment in accounting rates, IMTS typically "generates at least four times as much revenue as the average domestic interstate call; " [15] and

(2) Most international telephone calls are metered and charged on a usage sensitive basis, contrary to usage insensitive private lines that are more prevalent in domestic markets.

With robust traffic growth and margins like that recently experience in IMTS, a rigorous campaign to reduce accounting rates might force rate base regulated USISCs, particularly those carriers also providing domestic services and subject to a single revenue requirement for ratemaking purposes, to institute an across the board rate reduction. Higher than necessary accounting rates in effect preserve the appearance of high operating expenses leaving USISCs with justifications for slow rate reductions, particularly in the absence of competitive necessity.

The FCC's ISP was designed to prevent U.S. international service providers from offering a better division of revenues or other concessions to curry favor with foreign carriers. Absent the ISP, the Commission infers that prospective market entrants would agree to an unequal and lower split of an accounting rate, in exchange for a foreign operating agreement. Newcomers need such agreements with foreign carriers to secure direct routes, rather than having to hand traffic off to a competitor, which already has an operating agreement, or indirectly routing traffic via an intermediary carrier with which the newcomer has secured an operating agreement, i.e., "transiting" . Presumably, incumbent USISCs also could be whipsawed into agreeing to new concessions, e.g., refraining from pushing for lower accounting rates, in exchange for foreign carrier agreements to reject newcomer requests for an operating agreement, or routing disproportionate volumes of inbound United States return traffic flows to a particular correspondent.

The only way a USISC, generating a disproportionate volume of outbound traffic can reduce its settlement payout to a foreign carrier is through receipt of offsetting inbound U.S. traffic. Because a single foreign carrier often controls all of a nation's outbound international traffic, it enjoys significant leverage when more than one USISC vies for return traffic volume. The resulting settlement deficit increases when for certain routes, USISCs actually pay out more in the accounting rate settlement than what they collect in the form of tariffed rates, e.g., when a minute of IMTS is priced at $1.00, but the accounting rate is $3.00 requiring the U.S. carrier to pay $1.50, to its foreign correspondent leaving a net deficit of $0.50 per outbound minute. Without receipt of inbound settlements at $1.50 per minute, in compensation for the U.S. half of the international circuit and the domestic termination, presumably provided at a cost well below $1.50 a minute, the USISC would continue to experience a substantial deficit in settlement revenues.

The FCC's ISP is not absolute, as the Commission has established a waiver mechanism: "[E]ach proposed modification of the terms, rates, or toll divisions of operating agreements for services which more than one carrier or service provider offers to a particular foreign jurisdiction must be submitted to the Commission . . .." [16] But USISCs have not vigorously employed the waiver mechanism, and until its 1990 Accounting Rate NPRM, the FCC has taken a reactive, rather than proactive posture to prevent foreign carrier's invitations to "negotiate or impose a more advantageous settlement arrangement." [17]

5. <u>The FCC Proposes to Get Tough on Accounting Rates</u>

In its 1990 NPRM, the FCC proposes to take a more proactive role in accounting rate oversight, going so far as tentatively concluding that it has the authority "to establish international accounting rates, to determine and prescribe just and reasonable accounting rates, and if necessary, [to] condition Section 214 grants [of authority to operate international facilities] on the implementation of lower, more cost-based accounting rates." [18] Apparently, the Commission intends to engage in dialogue foreign carriers (mostly government owned PTTs), and to use its more direct regulatory oversight on USISCs to achieve cost-based accounting rates.

The Commission proposes to link its accounting rate advocacy to primarily domestically-based objectives like universal service, prevention of uneconomic bypass, network efficiency and elimination of unjust discrimination and unlawful preferential rates. [19] With these goals in mind, the Commission makes four concrete reform proposals to:

(1) permit a USISC the option of filing a letter with the Commission (rather file a ISP waiver application subject to a procedural timetable of 21-60 days) when proposing an accounting rate reduction; [20]

(2) streamline the Commission's time for acting on ISP waiver requests to 21 days and presumably to encourage USISCs to file more waiver requests proposing lower accounting rates if they benefit United States ratepayers; [21]

(3) engage foreign governments in a more frequent and vigorous dialogue on accounting rates, in part through International Telecommunications Union ("ITU") forums and application of ITU regulations and recommendations that arguably serve as a foundation for promoting cost-based accounting rates [22] and;

(4) promote international facilities shared use and resale, that if more available, also could foster downward pressure on accounting rates by making the private line accounting rates bypass opportunity two-way, rather than the possible more frequent inbound-United States option currently available. [23]

A "get tough" policy on accounting rates, has the potential for serious foreign backlash and retaliation. While the Commission has successfully conditioned grants of regulatory authorizations on the carriers it regulates, [24] it is quite another matter to affect the behavior and the financial performance of foreign carriers. For example, when the FCC attempted to influence the timetable for construction and activation of the TAT-7 cable [25] through direct negotiations with foreign governments, its activism was considered an intrusion of national sovereignty and was deemed a violation of the Government in the Sunshine Act. [26]

Recently the FCC considered and substantially rejected imposing reporting requirements and other means for overseeing the extent of participation in the U.S. telecommunications market by foreign-owned firms. [27] While the prospect of regulation could serve as strong leverage for achieving market access parity between United States and foreign telecommunications equipment and service providers, the Commission faced nearly universal opposition on grounds that such tactics would invite foreign retaliation and would violate this nation's commitment to treat foreign and domestic enterprises alike on regulatory and trade matters.

The FCC's CC Docket No. 86-494 focused consideration on:

> whether [the Commission] can, and should, consider proposing actions that might include, among other things, limitations on access to U.S. markets for foreign-owned carriers, enhanced service providers, terminal equipment manufacturers, and core equipment manufacturers from jurisdictions that are "closed" to U.S. telecommunications service providers and equipment manufacturers. [28]

CC Docket No. 86-494 represented the FCC's attempt to compare actual marketplace conditions with a theoretical model for international telecommunications regulation. The Commission designed this model with an eye toward assessing how deficiencies in international telecommunications goods and services markets could be resolved in furtherance of competition, efficiency, equity and national security goals derived from the Communications Act. [29]

Specifically, the Commission sought to receive information, primarily through mandatory reporting requirements, so that it could better evaluate the need for its regulatory intervention to serve the objectives of "open entry, non-discrimination, technological innovation, and international comity." [30] The Commission ultimately reduced the scope of its reporting requirements on foreign enterprises operating in the United States and apparently capitulated to the prevailing view that it should not use its arsenal of regulatory oversight to threaten foreign governments, nor should it usurp the Executive Branch of the federal government on how to address trade matters.

Notwithstanding the lessons from CC Docket 86-494, the 1990 Accounting Rates NPRM once again pits the FCC against foreign governments on what can be considered a trade matter. The Commission implies that foreign carriers and their government owners/regulators actively work to sustain artificially high accounting rates. In the most egregious cases where a foreign government sanctions inbound United States resale to evade accounting rate payments and the ISP, maintains an accounting rate that ignores declining costs or supports collection rates well in excess of what United States callers pay, the Commission proposes to "establish . . . determine and prescribe just and reasonable accounting rates." [31]

Such threats of unilateral action appear directed at foreign governments and their PTTs singularly, rather than primarily at the USISCs, who appear to have willingly capitulated to artificially high accounting rates. It seems that the Commission pays more attention on how its can affect and regulate the actions of foreign governments and carriers, rather penalize USISCs, with readily available regulatory sanctions, for their failure to negotiate accounting rate reductions.

Perhaps the Commission's initiative on international shared use and resale [32] indicates that a unilateral announcement only initiates the process for extensive bilateral and multilateral dialogue. The Commission's proceeding has languished in part because USISC tariffs no longer prohibit outbound resale, and an FCC statement supporting resale cannot supersede ITU deliberations or prevent other countries from maintaining restrictions that the Commission acknowledges will "preserve the present above-cost international accounting rate structure."[33]

The Accounting Rate NPRM may prompt renewed charges that the Commission too readily resorts to unilateral policy initiatives without appreciation of the need for international comity. Rather than risk exceeding the scope of what it can do without a government trade portfolio, the Commission should consider what it can do at home with the carriers it licenses. On this front, the Commission does mention that it might condition its Section 214 grants of service authority, but such power applies only to future applications.

The Commission could more effectively prod USISC activism to reduce accounting rates by prescribing cost-based rates for ratemaking purposes and treating as revenue some portion of the $1 billion overpayments made by United States ratepayers. Rather than constitute a confiscation of carrier revenues, such a restatement of carriers' finances would for the first time saddle the USISCs with responsibility and a direct financial burden for failing to bring accounting rates down to cost.

6. Conclusion

The FCC established the ISP to prevent PTT whipsawing, i.e., the ability of PTTs "to play two U.S. entities against each other, to manipulate traffic flows, and to retain a greater percentage of the accounting rate at the expense of a U.S. carrier." [34] If anything, lower termination costs to the PTT might stimulate outbound traffic and encourage the PTT to reduce its collection rates. More importantly, particularly if the FCC would impose some financial penalty on the USISCs for artificially high accounting rates, use of private lines or other bypass methods for inbound United States traffic should prompt USISCs to get serious on negotiating lower accounting rates in proper bilateral forums.

Lower collection rates, improved services, increased competition and the lack of market power possessed by a carrier--the very factors the Commission uses to consider requests for waiver of the ISP--are the likely positive outcomes if the Commission imposes financial risks on USISCs for failing to negotiate lower accounting rates and for failing to have reduced collection rates that could have been supported by lower accounting rates.

BEST COPY AVAILABLE

The reticence of USISCs to apply for waivers underscores the comfortable and profitable world in which they operate, despite a substantial net outflow of hard currency. PTT actions that disrupt the return flow of high accounting rate traffic, and not the ISP, may constitute the kind of pressure that forces accounting rates closer to cost.

Under the present ISP regime, USISCs are content to forego billions of dollars that could have reduced rates even further for United States ratepayers. Rather than target foreign governments for a risky jawboning initiative, the FCC could better create further downward pressure on rates, by forcing the USISCs to abandon the comfortable status quo and consider high accounting rates as lost corporate revenues.

In 1991, the Commission issued its Report and Order in CC Docket No. 90-337. [35] The Commission eased away from direct confrontation with foreign PTTs over their sovereign right to negotiate accounting rates, opting to concentrate on domestic "procedural reforms that remove any U.S. regulatory impediments to lower, more economically efficient, cost-based accounting rates . . .. [36] The Commission formalized its proposals to ease administrative burdens to the implementation of lower accounting rates and deviations from uniformity by United States international carriers. But it stepped back from unilaterally ordering changes in the process under which accounting rates are negotiated, or imposing any financial burden on carriers, domestic or foreign, that have profited from above cost accounting rates. The Commission instead relies on its expectation that individual carriers will perceive new incentives to negotiate lower rates, and for forums organized by the International Telecommunication Union to encourage cost-based rates.

The Commission's Report and Order refrains from getting tough, opting instead to allow the carriers more time to remedy the process, despite the expression of "concern[] that the present level of certain intra-regional accounting rates or other country-to-country arrangements suggest that U.S. carriers may not only be required to pay above-cost accounting rates, but that U.S. carriers are subject to discriminatory treatment in this respect." [37] Instead, the Commission created a Further Notice of Proposed Rulemaking in CC Docket No, 90-337 [38] as the vehicle to "continue our regulatory oversight," [39] and presumably also to serve as a veiled threat "to take further regulatory action" should U.S. carriers fail to negotiate lower accounting rates. [40]

The Further Notice directs the Common Carrier Bureau to conduct another study of international calling prices and to suggest remedies for the kind of overcharges it has already identified. The Further Notice also proposes to require U.S. carriers to report their progress in negotiating accounting rate adjustments, places greater emphasis on resale and shared use as a vehicle to prod downward accounting rates, and explores whether a better analytical framework might exist for assessing insufficient progress with particular nations.

The Commission again refrains from placing a cap on the amount it will deem a legitimate accounting rate payment, or placing the U.S. carriers under its jurisdiction on notice that the Commission will order refunds for overpayments. [41] The most drastic leverage it now appears willing to consider is conditional Section 214 authorizations to require US licensees to ensure nondiscriminatory treatment of all make telecommunications facilities, services and equipment markets competitive and supportive of previously articulated government objectives.

1. The United States has no significant balance of payment deficit for "record" services, e.g., telegram and telex traffic. "Traffic flows and financial settlements in the telegram and telex market largely offset each other." "INTERNATIONAL ACCOUNTING RATES AND THE BALANCE OF PAYMENTS DEFICIT IN TELECOMMUNICATIONS SERVICES, Report of the Common Carrier Bureau to the Federal Communications Commission, 6 (Dec. 12, 1988). [hereinafter cited as Common Carrier Bureau Report].

2. Regulation of International Accounting Rates, CC Docket No. 90-337, Notice of Proposed Rulemaking, 5 FCC Rcd. 4948 (1990) [hereinafter cited as Accounting Rate NPRM].

3. "[I]t is clear that the price of calling the United States has not declined as rapidly as the price of calling from the United States. Because American prices were lower to begin with, the differential in prices has increased. This has undoubtedly contributed to the continued and increasing imbalance in traffic flows and in turn contributed to the rapidly growing balance of payments deficit." 1. ABSTRACT

CNR is the acronym of the Italian National Research Council, one of the public institutions supporting non-profit research in Italy.
This paper will focus on the network used at CNR and its relationship with other national and international networks.
It briefly describes the experience gained during the development and management of the CNR's network and also the solutions adopted to integrate into one backbone network the four protocols TCP/IP, DECNET, SNA, and X.25.

2. INTRODUCTION

CNR is the acronym of the Italian National Research Council; one of the public institutions within which non-profit research projects are financed.
CNR is composed of many Institutes distributed in many Italian cities.
One of these Institutes is the CNUCE that is the primary Computer and Network Centre for the CNR and one of the primary network centres within Italian Networks.
This paper gives an overview of CNR Networks and of its relationship with other National and International Networks.
The CNR Network has at least two groups of users:
Academic users and Administrative users.
The first group uses all typical network services.
Researchers depend on electronic mail for communicating with each other in the world, some make intensive use of file transfer between hosts and the remote login facility.
The network is very important also for the Administrative users.
Since the CNR has its Central Administration Department in Roma, the exchange of administrative information between the Central Department and every CNR Institute in the country is very important.
To achieve this purpose CNR started a project (named "Institutes Network"). We must consider that the research activity of many of the Institutes in CNR do not have a close relation with Computer Science.
Today every CNR Institute has at least one MS-DOS Personal Computer connected via local area network (if possible) or via a switched asynchronous line to the nearest CNR Network Computer Centre.

3. THE NETWORK

The network topology includes 12 primary sites situated in as many cities. Each one offers network access to adjacent nodes.
Those Computer Centres were designed according to local needs; when CNR began to use computer networks, most communications were among machines running the same operating system. For example, in the beginning, most of the traffic was between VAXes running VMS over leased data transmission lines; DECnet is the natural protocol for such traffic.
Early applications were electronic messaging and terminal emulation.
There was a backbone for each protocol (DECnet, SNA, TCP/IP, X.25). Often between two Computer Centres there was more than one leased data transmission line (one for each protocol used); in addition the CNR network is integrated with networks belonging to other public institutions in Italy to form a heterogeneous (for protocols and institutions) National Network.

4. THE NETWORK EVOLUTION

In March 1988, the Minister of University and Scientific and Technological Research founded the GARR (Group for the Harmonization of Networks for Research).

From the work of this group derives the actual Italian network topology.
The present primary sites of the network are located in Milano (CILEA), Bologna (CINECA), Bologna (INFN/ENEA), Pisa (CNUCE-CNR), Roma (INFN/NIC), Frascati (ENEA/INFN) and Bari (TECNOPOLIS-CSATA).
The architecture of the backbone is made up 2 Mbs data transmission lines and multiplexors (TDM).
This structure is used for four different communication architectures (SNA, DECNET, TCP/IP and X.25) awaiting migration to ISO/OSI standards; in particular the X.25 subnetwork will be the experimental base for the ISO/OSI standards.
Since the GARR backbone was created, the CNR Network information groups have started to consider a new CNR network topology, with relationship to the new GARR backbone.
The CNR networking groups decided to work on the problem of the coexistence of heterogeneous families of protocols on a unique backbone.
Important decisions had to be made regarding the backbone architecture. Three possible solutions were considered:
a) a backbone made up of TDM's (such as GARR backbone).
b) a backbone based on a X.25 network.
c) a backbone based on a TCP/IP network.

5. INTERNETWORKING

By now, most small and big laboratories have computers connected using Local Area Networks (LAN) to exchange data.
We understood that our solution had to interconnect not single hosts but Local Area Networks all over the country.
The concept of networks of networks has emerged.
Our objective was to permit the coexistence of heterogeneous families of protocols in harmony with each other within an overall regional, national and international network plan that maximized access to network and its resources; namely we wanted give to the user, remote login, file transfer, and electronic mail services between heterogeneous network architectures.
We also wanted to consider the new OSI protocols to foresee the migration to this new network architecture.

From this point of view the solution using a backbone made up of TDM's was discarded.
Even though this solution permits the coexistence of heterogeneous data link protocols on the same leased data transmission line (namely we can say that we have realized an integration at physical layer), it has some disadvantages; for example:
- The network topology is not as flexible as we adopt a solution integrating the heterogeneous network architecture at a higher layer than the physical layer.
- This solution doesn't realize a good integration of the four primary network protocols used in CNR.
To realize this we had to select a protocol to provide a basic carrier service for CNR. This protocol is the one on which the backbone was implemented.

6. X.25 AND TCP/IP

Two protocols were considered X.25 and TCP/IP.
X.25 was considered since it conforms to the OSI specifications and permits the use of PSDN for our backbone. Some analysis of the PTT tariffs charged by ITAPAC (a volume charged network) showed that using the Italian PSDN as the primary backbone was not an attractive solution for CNR, besides X.25 is not as widely implemented as TCP/IP.
A question was: Can we adopt TCP/IP as the basic protocol for our backbone and also maintain the X.25 protocol as an experimental one?
Adopting a protocol to provide a basic carrier service shouldn't mean that only the one protocol will be permitted on CNR network. Machines running proprietary protocols should continue to communicate with each other using that one.
The solution was found in a Multiprotocol router.
The router chosen was CISCO for its technical merit and because it is widely used.
This means that the basic protocol chosen for CNR network is TCP/IP.
The CISCO is an IP router, a DECNET router, an OSI router, and an X.25 switch and, in the near future it will be able to carry SDLC frames between serial connections with SNA hosts.
The CISCO can also work as bridge and remote bridge.

Most of this functionality realizes what we named Network Layer Internetworking; but CISCO has another important feature, it can act as a router between OSI CLNS/CONS to permit a Transport Layer Internetworking. This feature will become more important in the near future as OSI becomes accepted.

7. MANAGEMENT

The network is managed by a Technical Working Group. This working group consist of representatives from the computer services staff in each Institution and it is responsible for the technical development, applications, availability and operational aspects of the network.

8. SERVICES

EARN, HEPNET, INTERNET, EUnet are the primary international Research Networks to which the CNR's backbone is connected; besides there are also access points to the National PSDN (ITAPAC) and to the IXI (International X.25 Infrastructure) that provides a basic X.25 carrier service operating at 64 Kbit/s between all the major Western European countries.
All the services offered by these networks are accessible to the CNR researchers.
From all these services emerges the Electronic-mail service. The most important and popular network service in the world.
For this service we achieve a high level of integration over such heterogeneous networks, by adopting the RFC822 addressing scheme.
It, therefore, appears to the electronic mail user that there is only one network. The users do not have to worry about where the network site they want contact is; the network can work that out and route accordingly.

GLOBAL TELECOMMUNICATIONS STANDARDS. WHO NEEDS THEM?

Ivor N. Knight
Vice President
Business Technology & Standards
COMSAT World Systems
Washington, DC.
U.S.A.

ABSTRACT

The spread of global telecommunications throughout the world is having a profound impact on international trade and politics. International events are unfolding in many communications forms as they occur. The limitation of this information to television and radio broadcasting is no longer true. Electronic mail systems, facsimile, satellite news gathering directly to the home and data services are playing major roles in the global observance of international events. If global standards were in place, even more sophisticated systems such as B-ISDN and HDTV would also be available to the public; but can we wait for internationally agreed solutions to the development of these standards or is the competitive development of new "de facto" standards the answer to the spread of new telecommunications technology?

This paper explores both sides of the issue in the light of radical restructuring proposals in the international telecommunications standards setting bodies such as the ITU and ISO.

Background

Well established international organizations provided an adequate forum for the development of telecommunications standards for the global growth of telegraphy and telephony. During that period, the emphasis was on better ways to operate these services and improvements to the transport systems to provide greater carrying capacity and, to a lesser extent, better quality. Though not simple, these services lacked the complexity of the new telecommunications services that have emerged in the 1980's and early '90s. In addition, the enhanced capabilities of modern transport systems resulting from the enormous advances in technology, are promoting the implementation of more new service types almost daily. The international standards bodies, such as the International Telecommunications Union (ITU) and the International Standards Organization (ISO), are rushing to reorganize their standards development process to keep pace with the demands for new global telecommunications standards and new "regional standards organizations" (RSOs) have been formed in an effort to at least ensure that telecommunications standards do not lag far behind the technology in regions of the world under their jurisdiction; regions where national regulation has been reduced and competition increased.

Many questions are being asked about (a) the ability of the international organizations to restructure in time to meet the new demands for standards development and (b) the true role of the RSOs (collaborators or competitors). Many questions are being asked about the possibility of the national governments "reinjecting" themselves into the standards development process in those countries that have recently liberalized their telecommunications policies, to "supervise" the standards processes more efficiently; and questions are being asked by those countries that have not yet followed a path of telecommunications deregulation about the merits of this process.

These events beg the question, do we really need a global standards setting process or can we rely on "de facto" standards set by the industry leaders?

The case for De Facto Standards

The ITU is the international organization responsible for the regulation and planning of telecommunications worldwide; for the establishment of equipment and system operating standards; for the coordination and dissemination of information required for the planning and operation of telecommunications services; and for the promotion of, and contribution to, the development of telecommunications and related infrastructures. It is a treaty organization and an agency of the United Nations. Over the years, it has done a sterling job of coordinating the development of

"recommendations" for radio and satellite systems in its committee CCIR and for telephony and telegraphy systems in its committee CCITT. With the advent of such new technology driven networks such as ISDN, it found that the pace of the introduction of new services, systems and networks was such that a complete reorganization of its modus operandi was essential to meet the needs of the changing global industry. This realization, (the CCITT first saw this in at its Plenary Assembly in 1984 and confirmed it in 1988; the ITU at the Plenipotentiary in 1989; and as a consequence, the CCIR at its Plenary Assembly in 1990), is to be applauded and if the ideas for the reorganization were put in place within a few months of the identification of the need - as in a large corporation - by this time we could expect that the ITU would be postured to tackle the new world order. Unfortunately this is not the case.

The ITU process by its very nature, demands that the restructuring concepts required the attention of several review committees le d by a "High Level Committee" studying the ITU as a whole and subservient committees studying the CCITT and the CCIR. The results of these studies will be reviewed by the member countries of the ITU at a special Plenipotentiary in September 1992 and if approved, the transition plan will extend until 1996 before the "new" management and operating arrangements are in place.

The bottom line here is that twelve years will have elapsed since the first warning signs of structural instability in the ITU process were first detected by the CCITT until the implementation of corrective reorganization. Twelve years in which the composition and operation of the global telecommunications business has changed dramatically in the first seven years; and who can predict the changes we will see in the next five. This, despite the fact that some of the best brains in the industry lead and participated in the various committees -- and the committees worked long and hard to reach consensus. As a hard working committee member said in response to a request for more speed, "You can go only so fast down a one lane road".

Maybe the ideal solution to the development of standards for the telecommunications business is through an international organization. But the fact of the matter is that the present process results in too little too late. The user community is much more educated regarding the telecommunications services they require and cannot tolerate delays in the application of new technologies vendors demonstrate due to a lack of standardization. The formation of the RSOs indicates clearly that global solutions are not timely and even these organizations are finding it difficult to keep up with the user demands and the technology on a "limited" part of the global networks.

Large manufacturers and telecommunications systems providers are offering attractive new services based on proprietary technology that are being gradually accepted as the norm. Waiting for these services to be embraced on a global basis through the existing international standards process slows growth and reduces efficiency of commerce.

The Case for Internationally developed Standards

Telecommunications history is dotted with expensive examples of parochial policies in standards setting. Developing countries are the biggest sufferers of the availability of "nearly the same" technology; but the highly developed countries are not immune to the problem and are especially vulnerable to incompatibility of fast developing and complex new software driven services so attractive to the sophisticated user. We are all aware of the problems (and waste of resources) associated with the interworking of T and E digital systems and NTSC, PAL and SEACAM video systems. Some of us are aware of the high cost to the industry of less obvious global telecommunications incompatibilities such as telephone tones and numbering plans; data system protocols and formating; electronic mail application programming interfaces; and basic system automatic testing procedures; not to mention the reduced efficiency and resulting usefulness of the lack of globally agreed standards for the comparatively new technologies of ISDN (supplementary services) and digital circuit multiplication equipment.

Today multinational manufacturing organizations are offering proprietary telecommunications equipment and systems to many countries around the world. No longer can one assume that country "y" will have brand "x" switching equipment. Country "y" may have more than one telecommunications system and several different types of switching equipment. Doing telecommunications business with country "y" would be a nightmare without some form of global standardization process.

A so-called "de facto" standards process has been tried and discarded in a number of countries and global regions. Marketplace competition is a way of life in many countries and is totally incompatible with the concept of allowing the correct standards to emerge by majority usage. Telecommunications is the nerve center of many international businesses and if a chaotic situation prevails in this industry, for even short periods, the impact on commerce in general is unacceptable.

The criticism that global standardization takes too long has some validity. The solution is not to discard the process but to improve it. This is precisely what the ITU High Level Committee is doing and similar actions are being undertaken in the ISO.

Summary

It is hard to argue against the need for the development of telecommunications standards on a global basis - particularly in the Pacific Ocean Region. Many companies in this region depend on rapid communications to reach and compete aggressively in global markets. Similarly, the rest of the world's trade centers need access to Pacific region centers of commerce to enhance their competitiveness. Rapid multi-destination cross border communications can only be established with multinational technical and operational agreements, i.e., telecommunications standards; but we can't afford the present delays in achieving these agreements.

Although the international standards setting organizations are undertaking a restructuring program, perhaps they are not going far enough. To meet the present needs of the telecommunications providers and users alike, some of the traditional and until now, sacrosanct, policies may have to be challenged. For example:

1. Let's agree to develop international standards in one language only. This conference, which is annually a great success, is an example of the virtue of this process.

2. It is vital to get "global" inputs in the standards development process; both developed and developing countries views are required. However, the realities of the economies must be taken into account and the prohibitive cost (financial and human resources) of travel to a central European location to express opinions, recognized.

Why can't we take the standards development process "on the road"? Meetings can be arranged in accessible places with the cost offset by the savings in translation and interpretation services as in number one above. Nomadic meetings have been very successful in the North American Committee T1 forum and to some extent, in INTELSAT.

3. As with communications, global standards development should not be restricted by any one set of local customs. Arrangements should be made to permit the process to take place throughout the year.

The Working Group set up at this conference to explore this subject will no doubt find other possible changes to increase the efficiency of global standards development. But whatever the findings, time is of the essence.

Emergency Services Telecommunications - A Specialized Telecommunications Need

Submitted By: Gerald J. Pierce
Summa Four, Inc.

1. ABSTRACT

Emergency Services Telecommunications represent an important, but specialized area of need. Wider opportunities are needed to discuss solutions developed for special areas. The PTC can offer a forum for such discussion.

2. CONCEPT: Typically, emergency services telecommunications are handled as a sort of hybrid entity which is somewhat external to the normal operations of a telecommunications operating organization.

The following broad definition is suggested for emergency service telecommunications;

"The use of existing and available technology to provide communications users, both governmental agencies and citizens, with the means to communicate the existence of emergency situations, and to coordinate response to these situations."

This paper is intended to present a conceptual model encompassing the range of possible emergency services telecommunications needs as they relate to the wide variety of areas represented by the membership of the Pacific Telecommunications Council (PTC).

A further intent of this paper is to stimulate an exchange of ideas among PTC members which will increase an understanding and awareness of the various solutions available to their organizations.

The approach taken is to present the model in graphic form, and then to discuss the range of solutions, citing both theoretical and real-world examples. The approach will address two areas of need suggested by the definition above, first; the need to communicate the existence of emergency situations, and second; the need to coordinate the response to these situations.

In many, but not all cases, the reporting of an emergency situation is done by a telecommunications end-user, typically a citizen. It will be seen that the nature and quality of such reporting is related to the general availability of telecommunications resources.

The coordination of the response to an emergency is virtually always a group activity, and more often than not, a governmental response. In many places, the questions of responsibility for, and jurisdiction over, the response can become considerably more complex than the actual response.

3. MODEL: The graphic model (Figure 1) is intended to represent the interrelationships of population size, population density and level of technology. Simply stated, the model traces the population density on an ascending scale vertically, and the population size on the horizontal axis.

This approach allows the creation of an hypothesis concerning the level of telecommunications complexity required for each of the two need areas - reporting and coordination. Briefly stated, the hypothesis is:

"The level of telecommunications complexity required reflects the population density and size in the area where the emergency occurs, as well as the overall level of technological sophistication available."

This may, at first glance, seem somewhat simplistic, because it could easily be restated as: "People use the tools available to them in an emergency." The purpose of the hypothesis is however, to stimulate discussion, and the key points to be addressed in the discussion are telecommunications complexity and deployment of technologically sophisticated systems.

The cases are selected to exemplify characteristics of the model, and are by no means all-inclusive. PTC members will readily identify areas within their own areas with similar characteristics. One area for future PTC meetings would certainly be to discuss solutions provided for a wide range of emergency services situations.

CONCEPTUAL MODEL

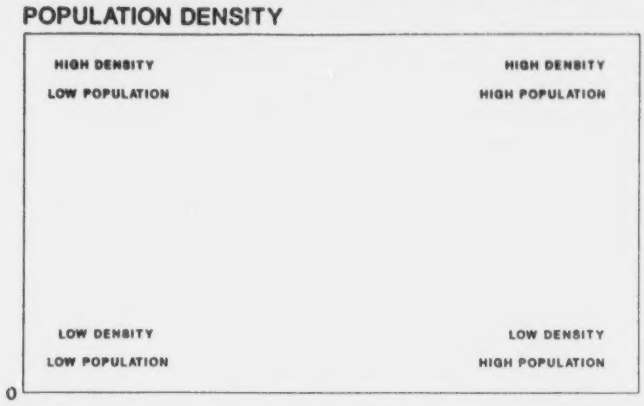

FIGURE 1

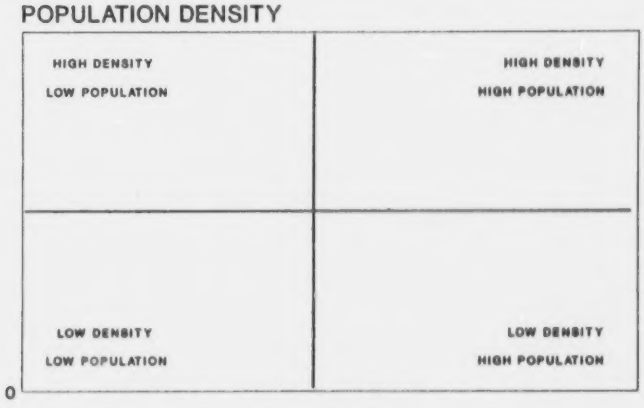

FIGURE 2

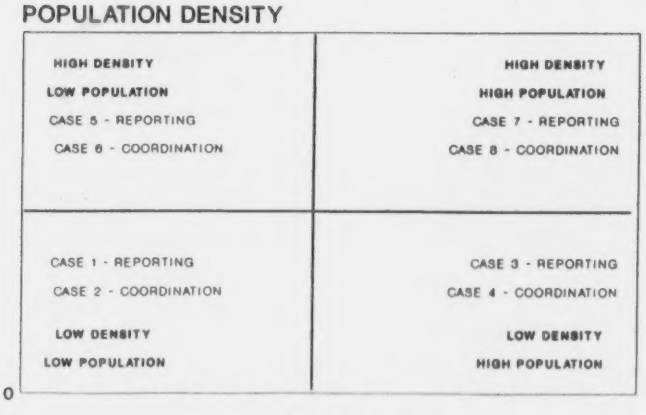

FIGURE 3

539

Clearly, to research all of the possible ranges throughout the area covered by the PTC membership would be difficult, if not impossible. Therefore, the cases represent a mix of actual and theoretical, and are individually identified as such. The writer has visited many of the Pacific Rim countries, and has endeavored to portray representative examples. Again, future PTC sessions will certainly afford opportunities for writers to provide actual, rather than theoretical cases. This potential will allow for sharing of related experiences.

The model may be subdivided into four quadrants (Figure 2). The lower left corner represents an area with low population size and low population density. Such areas typically have fairly simple telecommunications technology, and limited resources.

Self-help is the norm for most emergency situations. Note, however, that such locations may have the greatest potential for high-tech solutions which are both affordable and easy to maintain.

The lower right hand corner, by contrast, has high population density with small population size. Since the population is more concentrated, it is reasonable to assume that a higher level of technology will be deployed. The population will have access to some kind of emergency services, and have the means to report an emergency when it occurs. Increasing the level of technology deployed will encounter the barriers of cost and replacement of existing systems.

In the upper left hand corner, we have a large population size with low density. A representative case would probably involve a larger geographic area, so distance is a factor. Individual, isolated nodes will still rely on self-help, but the overall size of the population allows for the possibility of more sophisticated technology to coordinate responses from centralized operations.

The area in the upper right hand corner, of high population size and high density, is most easily identified as an area where high degrees of technological sophistication can be supported. It is both more efficient and more effective to use this level of sophistication and deployed systems will be more likely to be state-of-the-art.

4. CASES: A total of eight cases are presented, one for each quadrant for reporting, and one for control. Plot points are located to identify the cases.(Figure 3)

4.1 Low size/low density

This population area represents remote nodes of population, with limited resources because of size, and a need to call for help from outside when an emergency beyond their scope confronts the population. Areas of jungle, mountainous terrain, islands or desert might be classified in this category. In the Pacific rim area, areas in Irian Jaya, Papua New Guinea, Alaska, and the Phillippines for example, might be typical.

4.1.1. Case 1. Emergency reporting.

Emergency reporting in this area reflects the fact that isolation is characteristic and self-help is the norm. Thus, initial reporting is local, and will use whatever means is feasible. For situations of greater complexity, external expertise is required, and will be summoned if the situation requires it.

Communications in this environment may be used to summon self-help, as in calling a neighbor or summoning members of a volunteer fire department composed of community residents. Immediate medical assistance is often first aid, but communications are utilized to get directions on how to handle cases,again drawing on external expertise.

Identifying the actual location of the emergency is often a problem. Because of isolation and distance, the reporting person may not be able to specify the location. A means of identifying locations with precision is needed, most especially when situations requiring external aid arise (i.e. aeromedical evacuation).

Technology used may be open, copper wire circuits, or copper cable. When terrain does not permit the use of such technology, as is often the case in such areas, entrance link radio or microwave has been utilized, as well as satellite transmission.

4.1.2. Case 2. Emergency Coordination

As noted above, self-help is the norm. Initial coordination is by means of existing associations within the community or by ad hoc arrangements depending on the nature of the emergency.

Coordination is accomplished by means of local communications which may or may not be telecommunications. In truly isolated areas, runners or visual/audible signals may be used.

When specific types of emergency (cyclonic storms, volcanic eruptions, floods, forest fires) occur on a periodic basis, the community may evolve its own informal structure to respond to the problem.

Formal communications will again depend on the type of technology deployed. Most areas with the population characteristics specified are highly unlikely to have any wire-based communications. Radio is most typical, and that very probably is available only through some government agency.

Note, however, that as technology advances, technical solutions are becoming available to suit the needs of areas like this. Enhancements to the communications capabilities can take advantage of some highly advanced solutions.

One particularly appealing solution is the use of satellite earth stations. The latest advances allow an earth station to be small, rugged and with lower maintenance requirements. In an area of this type, such a method may be affordable.

In case of major disasters, Pekka Tarjanne of the International Telecommunications Union (ITU) has proposed the use of transportable earth stations for emergency communications. An ITU project has been proposed to facilitate the speedy movement and customs clearance of such equipment. (2)

4.2 Low size/high density.

This type of area is somewhat unique.It is typical of areas that are geographically remote, but well-established, with economic or physical conditions which allow, or perhaps even demand living in a concentrated area.

Populations living in remote mountain valley areas would exemplify this type of area. Pacific islands and other areas where the population is of high density because of the ability to easily maintain themselves with crops or hunting/fishing would also be representative.

4.2.1 Case 3. Emergency reporting.

Because of population density, more formal support means may exist, but they will quickly be overwhelmed by the demands of a large scale emergency situation. Nonetheless, the efforts using existing resources can be critical in saving lives, while other more distant, emergency response units are mobilized and sent to the scene.

Radio equipment is widely used for this type of application. However, the operating system may be required to have the ability to resist high degrees of heat and cold,as well as ambient humidity. Sealed cases for equipment are typical for such applications.

The maintenance of radio equipment can be difficult, but a variety of solutions have been developed. Modular assembly replacement, using spares maintained on site is desirable, but the feasibility of this approach in areas with climatic extremes must be analyzed carefully.

Note that such spares must also be protected environmentally just as the operational system has been. Self powering of systems is becoming more feasible with the advent of solar panels, and they are widely utilized.

4.2.2 Case 4. Emergency Coordination

Coordination of emergency response is done with local communications means first. As with the case above, radio is the typical means of coordination of help from outside the area, and, if available, from within the area.

Another means suggested by the ITU is the use of cellular telephone technology to be used by emergency responders.(3)
In the Southeastern U.S., recent hurricanes have caused significant damage when striking land and passing over populated areas. Normal communications have been made difficult or impossible because of severed or damaged cable or wire and fallen telephone poles. In recent cases, cellular telephones were issued to emergency workers and utility repair crews, and proved an effective communications means.

4.3 High size/low density

These are areas of great geographic extent, typically with small, dispersed population nodes. The total population is great in size, but so widely dispersed that it cannot effectively be mobilized to respond to emergencies. The challenge of distance is a major limiting factor in emergency response.

A representative area in the Pacific Rim would be the Australian outback, where large distance are common, and the population is in small towns and remote cattle or sheep stations.

4.3.1 Case 5. Emergency reporting.

Radio is the most commonly used means for emergency reporting. This area is ordinarily one with a centrally located single source of expertise, such as a provincial or territorial government.

This area will depend on self-help for most ordinary emergencies. When situations demand external assistance, it will likely be requested by radio. Distance is overcome by this means, and the delivery of aid may be in the form of instructions as, for example,how to handle a medical emergency.

Initial reports will be made by the means available, and again, non-physical means like radio or satellite link are most feasible. The cost versus return of constructing a cable link over long distances is prohibitive, unless it is somehow subsidized by government. Comparatively, a radio transmitter for common use, centrally located, can be quite cost competitive.

Both the radio and satellite solutions have been used in Alaska, where distance and isolation are factors, but extreme weather also comes into play.

Population is typically concentrated in native Alaskan villages and the use of satellite links for telephone communications in larger communities, and radio for smaller ones, is routine.

4.3.2 Case 6. Emergency coordination.

Again, the isolation of nodes creates special problems. Most emergencies are handled by the communities, and they draw on their own resources. This example draws on the real world, using the U.S. State of Alaska as its source.

In Alaska even larger communities use self-help, because time, as well as distance is critical. In temperatures ranging to 52 degrees below zero Fahrenheit, an injury may be further complicated by hypothermia or frostbite. Persons who are in good health are vulnerable to such injury if they are stranded by a vehicle failure.

Aircraft are widely used for emergency response, to carry responders or supplies, or to aid in searching for lost persons.

Major disasters, such as earthquakes or volcanic eruptions, both of which are not uncommon in Alaska, cause the government to become involved and mobilize resources from throughout the area. Military and paramilitary organizations are called into play, and another communications issue arises.

With multiple organizations using radio within range of each other, frequency coordination and spectrum allocation are important tasks. a balance must be maintained between allowing some normal communications to continue and serving the needs created by the emergency.

4.4 High size/high density

As noted in the introduction, this area is the most likely to use highly sophisticated methods of emergency communications.

Examples of this type of area would be most large cities. In the PTC area, cities like Singapore, Hong Kong, Tokyo, Sydney and Jakarta come to mind. The examples cited for the two cases are drawn from the U.S. experience, but similar examples could be found in other large cities.

4.4.1 Case 7. Emergency reporting.

The availability of telephone service is generally higher, making the telephone the most likely method of reporting emergencies.

In some areas of this type, brief dialling codes, typically of 3 digits, are used for emergency reporting. Depending on the sophistication of the telephone system, a caller may be automatically routed to the nearest emergency response coordination location, and, if individual line identification is possible, the caller's name and address may also be automatically delivered to the response coordinator.

This process is quite common in the United States, where the numbers 9-1-1 are utilized for direction of emergency calls. This number was initially designated by American Telephone and Telegraph (AT&T) in 1965, and subsequently in 1973 identified by the U.S. government, specifically the White House Office of Telecommunications Policy, as a means to easily handle emergency calls. (4)

When calls are routed, they are done using two common schemes. The first is called Basic 911 or B-911. It uses the originating exchange switch as the indicator of where to route the call. The problem with this approach is that the exchange switch serving area may not always match the boundaries of a police of fire jurisdiction. In the U.S., these jurisdictions are based on governmental units like cities, counties, towns and villages. An incident at or near a jurisdictional boundary may be responded to by units from several governmental agencies.

The second routing scheme, called Enhanced 911 or E911 is more precise. It utilizes the identification of the calling telephone to direct the call and search a database to provide the correct name and address.This has the added advantage of allowing responders to go to a location where a report has been begun, but terminated due to illness or injury. Lives have been saved by the use of this method.

In a recent study, conducted under the auspices of the National Emergency Number Association (NENA), 88.2% of U.S. cities over 100,000 population were identified as having Enhanced 911. When those currently planning to have Enhanced 911 were added to those already in service, the total rose to 99.4%. (5)

Clearly, for the larger cities, this means of emergency reporting is considered desirable. Note that physical location reporting requires some form of addressing, which can be a problem since address formats must be consistent.

Typically, areas of this type use a combination of transmission means. Fiber optic cable, copper cable, microwave and satellite are all utilized to deliver calls. In addition, the use of cellular telephones has expanded dramatically in the last few years. Experiments are underway to evaluate Personal Communications Networks (PCN) which will use radio and personal transmitters.

4.4.2 Case 8. Emergency coordination.

While U.S. 911 calls are routed by a variety of means, the reports are virtually all made over the public switched telephone network. By contrast, emergency response is almost always coordinated over the radio, although telephone links are used for secondary handling of an emergency report.

When an emergency call is delivered, it may be received by a variety of response organizations. Two major functions are provided in the emergency response center, typically caller a Public Safety Answering Point (PSAP). They are call taking, or receiving the report, and dispatch, or coordinating the response.Systems used to coordinate the response include maps, computer-based geographic databases, and radio. In some locations, data terminals have been placed in emergency vehicles. allowing more information to be sent to responders. Geographic vehicle location schemes are also used,allowing dispatch of the nearest unit to a specific emergency.

5. SOLUTIONS: The model was offered as a convenient framework to look at some typical areas, and to describe in a general way how they may report and coordinate emergencies, using telecommunications.

One truism is that no one person has all of the answers to a particular problem. As noted above, one purpose of this article is to allow PTC participants to look at a specific problem, and to open a forum for further discussions. The theoretical portions of the cases need to be expanded with further experience from PTC members. The area of emergency service telecommunications is specialized, and an excellent solution to a problem may not be transmitted beyond the area in which it is developed.

In the process of description, a variety of solutions were noted. At this point, a review of these solutions will be of use in order to better focus on their value.

5.1 Low size/low density

Solutions which are simple to use and easy to maintain can enhance both coordination and reporting. Advanced technology can be of help in improving communications.

5.2 Low size/high density.

Local capabilities may be adequate for common emergencies, but overwhelmed by major disasters. External expertise can be available with appropriate communications.

5.3 High size/low density

Isolation of nodes can be overcome by communications with a central support source. Non-physical means of communications prevail.

5.4 High size/high density

Wire communications are most common, and sophisticated, multiple media communications are commonly utilized. Reporting is by wire, and control is by radio.

5.5 General

In three of the four areas, non-wire communications are more commonly used. This reflects both demographic and developmental factors.

In areas where wire-based telecommunications have been deployed, the variety of solutions used includes the full range of technology in conjunction with wire-based applications.

By contrast, in the areas where non-physical means of total communications prevail, solutions tend to be implemented, and then rarely change over longer periods. Change is driven by the availability, cost and applicability of new technology.

6. CONCLUSIONS: It is clear that advanced telecommunications capabilities will continue to enhance emergency services communications. If cost were no object, the most isolated areas could be enabled to communicate with any other area on the planet. Technology is rapidly changing the telecommunications environment, and continues to allow more flexible means of communications to be deployed at lower cost and higher reliability.

The challenge for emergency services

telecommunications management is to identify, select and deploy the mix of technology that is most appropriate for each area within its area of responsibility. The issues of appropriations, maintainability, and affordability differ for each application, but to make the most informed choice, data must be available on systems in each of these areas.

The model discussed in this paper has allowed descriptions of need in a most general fashion. What is needed next is a forum for specialists in emergency services telecommunications.

GLOBALSTAR: Mobile Communications From Wherever You Are

Robert K. Swan, Space Systems/Loral
Robert A. Wiedeman, Loral Aerospace Corp.
3825 Fabian Way
Palo Alto, CA 94303

GLOBALSTAR is a satellite-based communications system that will provide mobile voice and data service as well as positioning service to users worldwide. It will allow users to make telephone calls with mobile and hand-held telephones from anywhere to anywhere -- and even routes calls through existing public and private telephone networks. GLOBALSTAR is a concept from Loral Cellular Systems Corporation, a new company formed by Loral Corporation and Qualcomm, Inc. These two companies bring unparalleled expertise in aerospace systems and ground communications technologies. Working together, they will join with limited partners to provide radio-determination satellite services (RDSS), and voice and data communications to users around the world.

1.0 SUMMARY

GLOBALSTAR enhances worldwide mobile services using a constellation of low earth orbiting satellites. The key feature of this system is its ability to offer low-cost, high quality and flexible services not currently available in areas not economical to serve terrestrially. It utilizes existing public and/or private network facilities to extend mobile user's Global connectivity. GLOBALSTAR subscribers will be able to communicate wherever and whenever they happen to be. Furthermore, such operation is deemed to be both profitable and low risk.

2.0 INTRODUCTION

On June 3, 1991, Loral Cellular Systems Corporation (LCSC) filed an application with the U.S. Federal Communications Commission for authority to construct a "GLOBALSTAR" system providing Radio Determination Satellite Services (RDSS) and Mobile Satellite voice and data services (MSS). Domestic operation within the United States is expected to begin in 1997. This paper will first give a general system overview, and then describe service offerings, ownership and revenue sharing, and expected revenue potential. GLOBALSTAR subscribers can expect highly reliable and yet low-cost mobile services to satisfy their communications needs.

3.0 SYSTEM OVERVIEW

The GLOBALSTAR system employs a constellation of 24 or 48 low earth orbiting satellites operating in conjunction with public switched telephone networks and/or specialized communications networks. The number of satellites depends on utilization of the system by various worldwide communications distributors. Each satellite has a capacity of over 2,600 duplex voice circuits and can also perform position determination at a rate of 17 million locations per hour. A bandwidth of 16.5 MHz in the L-band (1610.0-1626.5 MHz) is assigned to the satellite-user links while that of 33 MHz in the C-band (5199.5-5216.0 MHz & 6525.06541.5 MHz) is used for satellite-gateway or feeder links. Using compact and portable transceivers, subscribers can perform position determination and make local, long distance, and/or mobile to mobile calls by connecting through gateways and network facilities owned by various service providers. As shown in Figure 1, the entire network is divided into three segments: space, user, and ground as described below:

3.1 SPACE SEGMENT

A constellation of 48 LEO satellites in circular orbits at an altitude of 1,389 km (750 nautical miles) provides extended global coverage. These 48 satellites will be launched into eight orbital planes, with six satellites in each plane. Each orbital plane has an inclination angle of 52 degrees and each satellite has a 7.5 degree phase shift to the satellite in the adjacent orbital plane. Over the United States, such a constellation will guarantee full coverage with a minimum of three satellites in view as depicted in Figure 2. Satellites rise in the west and travel alternatively northeast and southeast with a period of about two hours. The average connection time for a user to a single satellite is about ten minutes. In the course of a phone call, the "make" and "break" user-satellite connections are carried out routinely and transparently according to a well-defined handoff procedure. Each body-stabilized satellite is equipped with a simple "bent pipe" transponder and an antenna having six elliptically shaped spot beams. This payload design approach allows GLOBALSTAR to adopt to many different global mobile system standards and avoids the use of complex on-board signal processing and satellite crosslinks. Spread spectrum modulation and Code Division Multiple Access technique will permit frequency reuse 288 times globally. In the L-band, the satellite delivers an EIRP of 29.8 dBW and has an G/T of -12 dB/K. Similarly, in the C-band, the EIRP and G/T is 10.4 dBW

and -20.4 dB/K, respectively. The satellite mass at launch is 265 kg, including 43 kg of fuel to support orbit insertion and an in-orbit life of seven and a half years.

3.2 USER SEGMENT

Transceivers may be handheld or vehicle-mounted units. They may be of simple mode design suitable for satellite RDSS/voice plus data operations. However, the most likely case would be dual mode units allowing the user to move freely between the terrestrial system and the satellite coverage area. Each of these units consumes less than one watt of average DC power and is equipped with a variable speed vocoder and an omni-directional antenna.

3.3 GROUND SEGMENT

3.3.1 GATEWAY STATIONS

Each station is equipped with two 2-meter C-band tracking antennas capable of transmitting an EIRP over a range of 32 to 44 dbW and having a receive G/T of 14.6 dB/K. During routine operation each station executes handoff procedures between satellites and between beams. The RDSS functions are performed either at the gateway stations or at the user terminal, while voice/data are routed through the gateways. Gateways equipment is designed to be added to existing cellular terrestrial facilities thereby sharing the switch.

3.3.2 NETWORK CONTROL CENTER

The NCC will perform registration, verification, billing, network data distribution, resource allocation, and other network management functions.

3.3.3. TERRESTRIAL-BASED NETWORK

The Public Switched Telephone Network (PSTN), the Public Land Mobile Network (PLMN) and other private and specialized networks are integrated into the system by means of the gateways. Connections are provided in the normal manner.

4.0 GLOBALSTAR SERVICES

GLOBALSTAR not only offers new and cost effective services, but also enhances existing terrestrial-based cellular telephone services. Included are: RDSS at the user's locale, in the user's moving vehicle, or at a remote site; services into areas not covered by terrestrial cellular and mobile systems; and global messaging, voice mail and other services. The front line of services is Radio Determination, Voice and Data.

4.1 WIRELESS MOBILE RDSS

The first service in this category is passive position determination where the user's position is computed by the user terminal itself. Applications for this service include emergency services, as well as recreational activities such as backpacking and boating. This service will be provided free at no charge to the user. The second is remote RDSS where the position of the user is requested. Its position is gateway computed and communicated to the user transceiver or to another third party. This service may be used in emergencies where the user needs to communicate his whereabouts to rescuers. The third is interrogating or tracking where a caller may request the gateway to communicate with a particular subscriber. Applications of this service include locating fleet vehicles, tracking hazardous waste shipments, monitoring military movements and locating stolen vehicles. All of the above RDSS functions in general may be combined with paging and messaging.

4.2 WIRELESS MOBILE VOICE AND DATA SERVICE

This service is provided to: (a) mobile or fixed users working and/or living in areas without terrestrial coverage, including subscribers traveling from one area to the other; and (b) private or specialized network operators including governmental agencies, commercial users, managers of fleet vehicles, emergency service providers, etc. Commercial users include rural facilities which are currently excluded by the PSTN or cellular network, utilities which require regular but infrequent asset monitoring, and security and resource management systems.

4.3 QUALITY OF SERVICE

The RDSS attains an accuracy of 300 meters for 80% of the time and less than 1,600 meters (one mile) all the time. Mobile voice is provided at "near toll" quality which surpasses that offered by the terrestrial based cellular. Bit Error Rate performance for 2400 bps data service is expected to be better than 10^{-6}.

5.0 OWNERSHIP AND REVENUE SHARING

LCSC will own and operate the network on a non-common carrier basis. It plans to form GLOBALSTAR Limited Partnership to raise capital and other resources for the construction of the System. Within this arrangement, partners will be able to make whole sale purchases of the satellite capacity and then retail the services directly to end users. For high reliability and low cost, the GLOBALSTAR system uses a large number of gateways in

BEST COPY AVAILABLE

order to optimize the usage of the existing network infrastructure. Service rates are therefore lower since capital expenditure and operating expenses are minimized. In addition, the low-cost gateway equipment is specially designed to be adopted to the terrestrial network equipment providing interconnection services. Participating carrier operators therefore will have ample incentives to adopt GLOBALSTAR services rapidly as a means of expanding their own service reach and capability to increase revenues and profits.

6.0 FINANCIAL PLAN

An income projection based on a business scenario [1] indicates that the revenue will grow from $141M in 1997 to $673M in 2006. This scenario was formulated according to a number of factors including the market demand, user equipment costs, service rates, capital investment and operating expenses, which are addressed below:

A conservative estimate of the urban and the rural users of satellite service from 1991 through 2006 is given in Tables 1 and 2, respectively. Data indicates that from 1991 to 2006 the satellite users in U.S. urban counties will grow fourfold, from a quarter of a million to 1.05 million. Similarly, U.S. rural users will increase close to fivefold from 560,000 to 2,620,000. For the RDSS market, predicted demand for position and/or messaging services is 2.6 million units in 1996, 3.4 million in 2000, and 4.2 million units in 2006. The premise behind this market forecast is GLOBALSTAR's ability to offer enhanced services with an attractive rates matching the terrestrial cellular (at $40 a month for a typical user averaging 100 call-minutes). It is expected that cellular rates will decline from current average rate of $80 per month to $40 per month during the system's life time. In addition, this market model takes into account not only the regional population growth but also its economic well being since the demand for mobile services is found to be related to potential subscribers's willingness to pay [2], which in turn depends on availability, quality, and price of the service offerings. The costs for the construction, launch and operations of 48 satellites in the first year is estimated to be at $829 million [1].

7.0 CONCLUSION

GLOBALSTAR offers a practical enhancement of mobile communications. Key system design features such as simple bent pipe transponder, open architecture, single satellite use by a user have been implemented in order to allow ease of adopting the system to existing networks for flexibility and quality performance. Its services are affordable. Its operation is profitable. More importantly, implementation of GLOBALSTAR promotes international cooperation.

TELECOM EQUIPMENT REMARKETING: A WINNING EFFORT

Andrew F. Silverman
A&A Connections, Inc.
530 South Henderson Road, Suite A
King of Prussia, Pennsylvania 19406

ABSTRACT

In recent years, the worldwide demand for secondary telecommunications equipment has grown dramatically. We must continue to aggressively investigate the global markets in search of new ways to "Connect the World".

It is important for PTC members to be made aware of the size, scope, and operation of the secondary market for telecommunications equipment and how it could affect their businesses. The secondary market is already growing at a fast pace in the United States. The domestic market is projected to grow at an annual rate of fifteen percent (15%) from $530 million in 1990 to $1,066 billion in 1995. The international market is beginning to emerge and is expected to eclipse the domestic market within the aforementioned forecast period.

The secondary market consists of end-users, distributors and telephone companies who need a continuous supply of quality equipment for their current communication requirements at an attractive price.

The secondary market provides reasonable features and continued parts supply, as well as an alternative source for price, service & quality. This market is also an avenue to service authorized "new equipment manufacturer's distributors", such as International PT&T's and interconnects, who require equipment to service an existing installed base that can longer be provided due to obsolentity or scarcity.

A&A Connections, Inc. is leading the way in developing International trade in the secondary telecommunications market. Our goal is to organize the market place in order to provide an answer for improving the telecommunications facilities in lesser developed countries worldwide.

PTC consists of major users, user associates, manufactures, suppliers, distributors, and service companies; all of which require the maintenance of an orderly market for surplus, used, and refurbished products. Such support is critical for stabilizing residual values in communications systems investments made by end-users.

Manufactures express concerns about the impact of used products on new system sales. Surplus and used equipment suppliers claim that their total market represents less than (1%) of new annual sales and feel that these manufacturers' concerns are exaggerated. Users and secondary market suppliers believe that this exaggerated fear occurs as a result of the manufactures failure to adequately maintain their distribution channels. If manufactures organized their distribution network to better accommodate end-users' needs for used and refurbished equipment through established and authorized channel outlets, the erosion of the customer base (maintenance, adds/moves/changes, and after sales service) could be stabilized.

Manufacturers and their distributors endorsing both new and refurbished equipment enhances the commitment to serving end-users for the long term. Used equipment will grant those users who are unable to afford the newest products, such as in lesser developed regions, or end-users who may not need the newest technology a viable alternative until the newer products make practical sense.

There is enormous opportunity for used and refurbished equipment to become an integral product mix for manufacturers, distributors and secondary marketers. If efforts were combined in an organized market place, complete support of equipment would be guaranteed. The result would be long term, end-user satisfaction.

For a winning effort to be achieved, the secondary market supplier must be considered an invaluable player in the telecom industry.

COMPETITION SAFEGUARDS IN TELECOMMUNICATIONS: AN ISSUES PAPER OF THE INFORMATION TECHNOLOGY ASSOCIATION OF AMERICA

David Peyton
Senior Director of Government Relations
Information Technology Association of America (ITAA)
(Formerly ADAPSO)
Arlington, Virginia U.S.A.

Dana Theus

EDS, Inc.
Washington, DC U.S.A.
Chair, ITAA International Communications Committee, 1989-91

1. ABSTRACT

The worldwide information technology (IT) industry, a primary engine of global economic growth, depends on the output of a related industry, telecommunications, to reach its customers. Telecommunications Operators (TOs) are becoming potential competitors in IT by offering value-added data services and systems integration services. Where TOs enter the information technology services marketplace, competition (or antitrust) policy must be implemented to address the incentive that the TOs have to compete unfairly. Competitive safeguards typically address the structure of monopoly TOs, through creation of a fully separated subsidiary, or the TO's conduct, through cost accounting rules and tariffs. Debate and discussion around the world show that, although tradeoffs will be resolved differently in different national and regional contexts, the issues are indeed universal.

2. INTRODUCTION

The worldwide information technology (IT) industry has become a primary engine of global economic growth. For 1990, worldwide information services expenditures were estimated at US$200 billion, and information systems (including hardware) at US$865 billion (both figures exclude telecommunications revenues). For 1995, these numbers are forecast to rise to US$420 billion and US$1.5 trillion, respectively. North America, despite the highest market penetration, still enjoys a compound annual growth rate of 13%, while Europe and Asia stand at 19%.[1] There are now about 100 million personal computers installed worldwide, or one for every 50 people.[2] In country after country, policy makers are encouraging their nation to develop a strong footing in IT, whether in mainframe or personal computers, semiconductor chips, software, or computer and communications services. IT is being seen more and more as "strategic" or "critical" for national economic performance and worldwide economic competitiveness.

The IT industry relies on the output of a related industry, telecommunications, to reach its customers and meet their information needs with maximum efficiency. While the two are generally spoken of as recognizably separate industries, the nexus between them in data communications continues to raise intricate policy and regulatory questions.

Despite strong trends towards competition, basic telecommunications services that are provided over monopoly-held telecommunications infrastructure facilities -- both voice and data -- remain a controlled market in most countries. Generally, telecommunications services are reserved to government-franchised telecommunications operators (TOs),[3] often monopoly enterprises. Where competition is allowed, it is usually regulated or limited so as to further public policy objectives. Thus, worldwide, the IT industry must rely on underlying TO services to reach its customers. Without these underlying telecom capabilities, many computer and information services firms would be unable to provide their services efficiently and effectively.

Many ITAA member companies offer data processing and other IT services globally, using international telecommunications networks. Despite competition from TOs, IT services companies still must rely on the TOs to supply them with underlying data and voice transport. Where such competition between TOs and independent IT services providers does occur, competition (or antitrust) policy must be implemented to address the incentive that the TOs have to compete unfairly:

- by providing their own operations preferential access to telecommunications capabilities; or
- by using revenues from the underlying monopoly telecommunications services to subsidize the provision of competitive value-added services.

Precluding TOs from entering competitive lines of business may be unrealistic. Thus, the use of other mechanisms or safeguards -- including structural separation requirements, nonstructural behavioral safeguards regulation, and the ability to resell TO-provided monopoly services -- should be considered to ensure that all providers of competitive services have a fair chance to succeed. ITAA commends the detailed position statements on telecommunications competition and safeguards issued by the International Chamber of Commerce as a prominent statement from world business on the subject.[4]

This paper examines the various regulatory options which have been considered and tried in countries seeking to ensure fair and open competition in the value-added communications and information technology market. ITAA hopes that this discussion paper will accomplish two major goals:

- promote the application of competition (or antitrust) policy principles in telecommunications policy development; and

- motivate the international IT services industry to advocate such policy development to protect its unique interests in this area.

By drawing from the debates and decisions about the intersection of competition and telecommunications policy in various countries, ITAA hopes to further the international debate and to ensure that TOs and computer services vendors can make their respective contributions to economic progress through information technology.

ITAA represents more than 550 firms offering a wide array of services, including those based on the use of telecommunications networks, such as cash consolidation and financial management services; computer-aided design and manufacturing (CAD/CAM); computer reservation services; credit-card verification; electronic data interchange; electronic funds transfer; electronic mail; and payroll processing.

While almost all of ITAA's members are based in the United States, the Association has taken a lead role in promoting its industry worldwide through the World Computing Services Industry Forum, now comprising 23 national associations. In conjunction with some of these other bodies, ITAA sponsors the biennial World Congress of Computing Services.

3. THE NEED FOR COMPETITIVE SAFEGUARDS

For the foreseeable future, IT services companies, will remain dependent on TO transmission, whether by leased lines or public switched services, to reach their customers, whose data they are to process or deliver. Specifically, independent vendors need switched and dedicated TO services with all of the following characteristics: two-way; very low error rate; highly reliable (uptime); ubiquitous; reasonably priced; consistently provisioned; and having standard interfaces for user equipment.

ITAA last year submitted the results of a survey to the U.S. District Court that administers the AT&T Consent Decree. The survey showed that major ITAA members -- most of which operate internationally -- are still 99%-plus reliant on TOs in the U.S. to reach their customers. Indeed, as computer and information services move to higher speeds, fiberoptic cable and other digital media, almost always owned and operated by TOs, will be the medium not of choice but of necessity.

As long as this dependency relationship exists, there will be a need for competitive safeguards. Generically, safeguards are provisions of law, or regulations having the force of law, constraining the conduct of monopoly firms so as to reduce greatly the possibility of anticompetitive conduct.

This section will describe the specific need for safeguards by listing the different ways in which TOs have used, or can use, their franchised monopoly position unfairly to advantage their own competitive service offerings at the expense of competitors. Generally speaking, the service offerings provided by TOs and used by computer and information service vendors are leased-lines (or equivalent), public switched dialup, and public data network services.

Published TO tariffs could incorporate many of these safeguards. In particular, information disclosure, unbundling, and resale[5] could easily be incorporated into a tariff rather than, or in addition to, some other regulatory measure. As long as all changes must be publicly reviewed and approved, incorporation of safeguards into tariffs may be preferred, because it provides users with a comprehensive reference document. The form and manner of implementing safeguards may differ from country to country for various reasons, and this issues paper concentrates on the content, rather than form or manner of implementation, of the safeguards.

3.1 DISCRIMINATORY ACCESS TO RESERVED SERVICES AND INFRASTRUCTURES

TOs can bundle their service offerings so as to create an "all or nothing" package for users including IT companies, forcing them to buy features they do not want or need so as to obtain the ones they do want. Providing itself with unbundled services can allow the TO to offer flexible service offerings **at a lower price** when competing in the IT services market.

TOs can give their own operations superior network access in terms of features, functionality, transmission quality, and reliability, and provide its own operations with superior or more prompt installation, maintenance, and repairs.

3.2 PRICES, TERMS, AND CONDITIONS

A TO typically is required to establish and publish tariff rates for its monopoly facilities and services at levels that cover costs and provide an appropriate return on investment. It might charge its customers these tariffed rates, while providing its own competitive enterprise the same facilities and services at cost or below.

Through a lease contract, a TO could impose less favorable terms and conditions on its competitors that are not imposed on itself or its own affiliate, when providing a competitive service. Such terms might relate to price, length of contract, rights of renewal, maintenance and repair, and circuit quality.

3.3 DISCLOSURE OF NETWORK INFORMATION

TOs can fail to disclose technical information needed for effective interconnection with, or use of, the public telecommunications network.

TOs can withhold technical information until the introduction of their own competitive services, thereby preventing competitors from developing a timely marketing strategy to compete with the new TO service.

TOs can use proprietary network information, not available to their competitors, to develop new service offerings.

TOs can withhold business-related information about subscribers or can require subscriber consent[6] before releasing such subscriber information to independent vendors, while using that data in its own marketing efforts. Such subscriber-related data may include touch-tone phone ownership or detailed call reporting data.

3.4 CROSS-SUBSIDIES

TOs can use protected revenues from monopoly services to lower prices artificially in competitive services, through misallocation of joint and common costs. Such predation could succeed in driving less well-funded competitors out of the market.

3.5 EXISTING ANTITRUST AND COMPETITION LAW REMEDIES AFFORD ONLY AFTER-THE-FACT RELIEF, NOT PREVENTION

In countries where TOs may be treated as regular commercial entities for the purposes of antitrust or competition law, the same remedies are technically available against them as against other companies engaging in anticompetitive conduct. Thus, a private party, as well as a government body, could bring an action to stop the offending practice and to seek monetary damages to compensate for lost profits. However, long and expensive antitrust litigation is not suitable or practical protection. What is needed is specific legislative or regulatory safeguards designed to **prevent** competitive injury, rather than **remedy** it after the fact.

Such regulation is desirable because a smaller, aggrieved party suffers a disadvantage if forced to seek antitrust relief in the courts against a larger, better-financed party. By the time a smaller company succeeded in obtaining a judgment, he might well have been forced out of business. When the larger party is a part of the government itself, as many TOs are, the odds become even more formidable. Sound public policy should be fully developed, so that all competitors are treated fairly, not just the ones able or willing to resort to legal recourse.

4. ANALYSIS OF ALTERNATIVE SAFEGUARDS

This section describes the benefits and potential negative consequences (costs) of various safeguard options.

4.1 EXCLUSIONARY RULE PREVENTING TOs FROM ENTERING COMPETITIVE LINES OF BUSINESS

The most far-reaching way to prevent anticompetitive activity by a TO is to prevent it from offering competitive services in the first place, either through legislation or, as in the U.S., through a judicial decree. The objective is to remove the very source of anticompetitive conduct: the TO's ability and incentive to take advantage of competitors, stemming from the simultaneous operation of monopoly and competitive services.

Benefits. This is the surest way to preclude anticompetitive conduct.

Costs. There is potential loss to the market of TO expertise, scale and scope economies.

4.2. STRUCTURAL SAFEGUARDS, BY WHICH A TO, UNDER GOVERNMENT MANDATE, CREATES A FULLY SEPARATED SUBSIDIARY BEFORE ENTERING COMPETITIVE LINES OF BUSINESS, WITH SPECIFIC CONTROLS ON DEALINGS BETWEEN THE TO AND ITS COMPETITIVE SUBSIDIARY

The need for competitive safeguards is relevant whether or not the TO provides monopoly and competitive services in structurally separate, arm's-length entities, or on an integrated basis within a single organizational entity. Under structural separation, implementation of the safeguards may be simplified to the extent that activities are kept separate. Separate activities are easier to monitor, and most importantly, the needs of the separate competitive company will drive the monopoly to provide appropriate services to all competitors on fair and equal terms. The choice between requiring structural separation and allowing integration is a matter for the independent regulatory authority to decide, based on national circumstances and preferences.

Generally speaking, the U.S. Federal Communications Commission has found that a separate subsidiary must meet a number of requirements:

- have separate officers and employ its own personnel;
- maintain separate books of account;
- utilize its own facilities;
- secure its own debt financing;
- obtain all transmission capacity from affiliated carriers pursuant to the terms and conditions appearing in the carrier's published tariffs (or if service is provided pursuant to contract, at the same rates, terms, conditions that such service is provided to third parties);
- conduct all transactions with affiliated carriers, other than those involving tariffed transmission services, on an arm's-length basis pursuant to written contracts; and
- acquire all research and development services and equipment from affiliates on a fully allocated cost basis.

Benefits. This alternative eliminates most joint and common costs, thus reducing the opportunities for cross-subsidization; exposes dealings between parent TO and affiliate to inspection so as to prevent more favorable terms being offered to the affiliate than to independent IT services vendors, therefore constraining the TO to deal with affiliate in the same way that it deals with all other parties.

Costs. The TO must accept the costs of running a separate corporation, with separate facilities and staff. Some economies may be lost.

4.3. NONSTRUCTURAL SAFEGUARDS CONSISTING OF REGULATORY REQUIREMENTS ENFORCED BY AN AGENCY INDEPENDENT OF THE TO

602

4.3.1 ACCOUNTING RULES. The TO can gain an unfair advantage over its competitors unless proper cost allocation and accounting procedures are in place to identify and assign costs to the TO's monopoly or competitive enterprises. The TO can gain an unfair advantage by overallocating operational costs and improperly assigning investment risks to the monopoly activity, where recoupment is virtually assured. This activity provides market-distorting benefits to the TO's competitive affiliate by underallocating the costs and risks of its competitive activities where the vicissitudes of the competitive marketplace provide no assurance of recoupment. Thus, accounting safeguards are generally designed to help detect any attempt by a TO to shift the costs of the nonregulated enterprise to regulated activities.

An effective cost allocation and accounting system should be designed to account for the monopoly and competitive offerings of a TO as if the two were offered by unaffiliated entities. All TO offerings should therefore be categorized as either monopoly or competitive, with books of account providing complete and separate financial statements for each. Accounting principles and rules should be promulgated properly to identify and assign to each the appropriate costs, revenues, assets, and liabilities.

This approach not only reduces the potential for improper cross-subsidization, but also facilitates the development of a detailed accounting system that can provide the full range of data needed for cost-based tariff offerings. Cost allocation and accounting systems should incorporate the following principles.

Cost Allocation. All recorded historical costs should be allocated between monopoly and competitive activities using a fully-distributed costing (FDC) method rather than incremental costing methods. The FDC method assigns an appropriate portion of all investment and expenses -- both direct and indirect or overhead -- incurred in conducting these activities. Costs should be directly assigned to one or the other activity based on cost causation. Common costs that cannot be directly assigned should be apportioned between monopoly and competitive activities using the most precise allocator available, typically the ratio in which directly assigned costs are recorded. The method of allocation used should minimize subjective judgment and facilitate objective review.

Assignment of Investment Risk. All of the risk for capital investment should not be borne by the monopoly ratepayer when assets are acquired and used jointly for providing both monopoly and competitive services. The TO should apportion the asset value of the jointly used equipment, at time of acquisition, to the books of the monopoly activity and to the books of the competitive activity respectively on the basis of peak forecast use by the competitive activity as projected over the depreciable service life of the asset.

Transactions With Affiliated Entities. Whenever the TO's monopoly activity sells to, or purchases from, the competitive activity, the price of the transaction should be based on the net book cost or should reflect fair market value. If the monopoly buys from the affiliate, the transaction must be accounted for at the lower of fair market value or net book cost. If the transaction is a sale from the monopoly to the competitive side, it must be accounted for at the higher of fair market value or net book cost. This practice is intended to avoid having the monopoly activity purchase assets with monopoly revenue merely to transfer them to the competitive activity at an advantageous price, thus harming both the monopoly ratepayers who bear the burden of the purchase, and the competitors of the TO's competitive activity, who have to pay full price for comparable assets.

Employee Designations. The preferred method of allocating salary expenses between monopoly and competitive activities when TO employees work in both areas is by predesignating each employee to one or the other enterprise. Then, "exception time reporting" can be used to account for time spent on the other activity. In the absence of predesignation, each employee would have to account for time on an hour-by-hour basis, a time-consuming and less practical method when thousands of employees may be involved.

Accounting Procedure. A formal system of internal control should be established to compile the necessary documentation for an effective accounting system, producing separate books of account for the monopoly and competitive activities respectively, and ensuring the credibility of the accounting procedure.

Compliance Audit. The TO should file annually with its regulatory authority an opinion obtained from independent auditors that the TO is complying with cost allocations and accounting plan.

Benefits. Rules such as fully distributed costing (FDC), described above, help to prevent TOs from ignoring or concealing some costs altogether, or from misallocating costs away from competitive services to reserved services, so as to prevent predation through cross-subsidized pricing.

Costs. In many instances, cost allocations are ultimately arbitrary; compliance can be burdensome; and regulatory agencies will almost certainly be understaffed for review purposes relative to the tariffing and accounting departments of TOs, which are larger organizations.

4.3.2 REGULATORY SAFEGUARDS

If the responsibility for the provision of monopoly services and for regulatory oversight is vested in the same entity, the potential exists for a conflict of interest in the process of developing, approving, and implementing competitive safeguards and other regulatory requirements. Therefore, all regulatory safeguards should be administered by an independent governmental authority with responsibility for overseeing the monopoly activities of the TO. In addition, this authority should provide an appeals function to settle disputes that may arise between a TO and its competitors or customers that cannot be settled between the parties themselves. So as to avoid conflict of interest, this authority should be independent of the TO organizationally, financially, and legally. Any party with a grievance -- user, competitor, or TO -- should be permitted to bring a case before the authority.

Rules governing the provision of access to the TO's facilities and services, and prices to preclude discrimination against competitors by TOs.

Generally speaking, these rules require a TO to provide its information service competitors with access to regulated services and facilities at the same rates,

603

terms and conditions that such services and facilities are made available to its own information service operations. These rules also apply to the TO's provision of installation, maintenance and repair services.

Benefits. TOs are prevented from treating affiliates advantageously relative to independent competitors.

Costs. TOs remain free to favor affiliates in new ways that are not specifically prohibited. It may be very difficult to ascertain whether a TO is complying with its obligation to provide equal service, and in services such as data communications, even a very small variation in quality can make a major marketplace difference.

Information disclosure rules as to technical specifications and customer usage data, so that such data are provided to competitors at the same time, and on the same terms and conditions, as to a TO affiliate, if at all.

With regard to technical data, the TO routinely plans and implements technical changes to the network infrastructure for upgrading capacity and function. All competitors rely on this infrastructure to provide their services. If all competitors are not made aware of the network changes with sufficient advance notice to adjust their service offerings, the TO's competitive activity would be unfairly advantaged. Therefore, the TO must publicly disclose technical information on network changes, including changes to network interfaces, that affects the provision of competitive services or the attachment of customer premises equipment with sufficient lead time to permit competitive service providers and equipment manufacturers to adjust their offerings accordingly. As mentioned before, customer data includes, for example, touch-tone phone or detailed call reporting.

Benefits. These rules prevent a TO and its affiliates from withholding information in its possession, solely as a consequence of its monopoly franchise, so as to disadvantage competitors.

Costs. TOs may be compelled to release technical information prematurely; some customers may prefer that data about them not leave the TO to go to any party, including a TO affiliate. (Relevant data protection regulations or self-regulatory policies of the TO may address this concern.)

4.3.4 RIGHT OF (NON-TO) LESSOR TO RESELL CAPACITY IN LEASED FULL-PERIOD CIRCUITS

Benefits. Permitting arbitrage undercuts a TO's ability to charge anticompetitive, non-cost-based rates.

Costs. Resale may also undercut cost averaging sanctioned as a matter of social policy to keep rates down for rural or isolated customers.

4.3.5 UNBUNDLING REQUIREMENTS

Most fundamentally, these rules generally require TOs to segregate (or "unbundle"), and make separately available, the transmission capacity underlying their information service offerings. Moreover, under open network policies[8], underlying discrete basic service elements are to be unbundled, each separately available under tariff.[9]

Benefits. Unbundling permits users to acquire and pay for only those services which they want and need and allows competitors to acquire the underlying transmission service needed to offer services comparable to those of the TO.

Costs. Unbundling may deprive a TO of marketplace flexibility.

5. CASE STUDIES: UNITED STATES, EUROPEAN COMMUNITY, AND JAPAN

This narrative section describes the approaches taken by political entities having the greatest experience to date with competitive safeguards: the U.S., the EC, and Japan. It concludes with shorter descriptions of relevant activities in several other jurisdictions.

5.1 UNITED STATES

The interplay of antitrust law and telecommunications policy has occurred in the U.S. in a way not likely to be repeated in other countries. However, the fundamental issues of control of monopoly conduct are the same, and the early inception of new transmission technologies has forced the weighing of the public policy questions which this issues paper discusses. TOs in the U.S. have long operated as private shareholder-owned, but publicly regulated, utilities. As regulated entities, these TOs are under common carrier obligations to provide nondiscriminatory service to all who desire it at tariffed rates. The former AT&T's monopoly for long-distance (as opposed to local) service was de facto only and not a matter of exclusive government concession. Thus, technological progress, in the form of low-cost microwave transmission, created an opening for the competitive offering of long-distance telephone services.

Once a competitor, MCI, entered the long-distance market with microwave facilities on high-volume routes, AT&T was claimed to have competed unfairly by providing MCI with poor-quality connections to its local loops. MCI succeeded in obtaining private antitrust relief through the federal courts. At the same time, the U.S. Department of Justice, in seeking structural relief in court, presented so much damaging evidence of other anticompetitive conduct that AT&T agreed in January 1982 to be divested of its local operations as of January 1, 1984. The U.S. District Court handling the case held public proceedings as to the terms of the decree to end the government's antitrust action and issued a Modified Final Judgment in the summer of 1982.[10] The newly divested Regional Bell Operating Companies (RBOCs)[11] were to retain their local service monopolies, antitrust considerations remained a factor.

To prevent reoccurrence of anticompetitive conduct, parties agreed in 1982 to exclude the RBOCs from three core lines of business:

- long-distance transmission service;
- telecommunications equipment manufacturing; and
- information services, defined in a manner similar to enhanced services under the FCC definition.[12]

The rationale for the line-of-business exclusion was the same as that of divestiture itself. The monopoly TO -- which has bottleneck control of the local exchange facilities essential to the provision of competitive value-added services -- inevitably has the ability and the incentive to compete unfairly. Despite much debate, litigation, and legislation considered by the U.S. Congress, those restrictions on RBOC TOs have remained largely in place today. RBOCs have been allowed to enter these businesses on a case-by-case basis, only to the extent that they could obtain specific waivers from the MFJ court, contingent upon convincing the judge that such entry would not have a significant anticompetitive effect.

ITAA appreciates that an exclusionary rule will have less appeal in other countries where the TO plays a more integral role in social and industrial policy. Based on the proven record of abuses, both past and recent, however, ITAA has supported the U.S. exclusionary rule for information services[13] while being willing to consider the use of structural safeguards -- that is, requiring entry through separate subsidiaries -- as an alternative.

The consent decree litigation has become too complex to be worth retelling in full, but essentially every substantive and procedural issue has been contested and every decision appealed. The federal judge in charge has decided, interpreting a strict legal instruction from a higher court and expressly against his own judgment, to lift the information services restriction on the RBOCs. At the same time, he stayed that order pending appeal. The RBOCs successfully appealed the stay, and the further appeal by opposition IT services groups to the Supreme Court was unavailing. Thus, today the RBOCs are free to enter the IT services business in the U.S., with few restraints. The MFJ now requires only that their information services activities not involve long-distance services, except pursuant to any waiver. As discussed below, existing regulatory requirements have not proved satisfactory to IT services groups. IT services groups are continuing to appeal the district court's ruling on its merits, as the judge anticipated.

Proceeding in historical parallel have been the regulatory efforts of the Federal Communications Commission (FCC) in its three Computer Inquiries, dating to the 1970s. These proceedings were occasioned by the regulatory need to determine where the FCC's authority over telecommunications, under the U.S. Communications Act of 1934, ended and where the competitive offering of computer services started. The agency has followed the guiding principle that it should regulate as little as possible and leave as much to market forces as possible. This distinction emerged as a fundamental concept:

- "Basic"[14] services, narrowly defined, that TOs must offer under tariff in performance of common carrier obligations,[15] essentially voice and data transport; and

- "Enhanced"[16] services, broadly defined, up to and including protocol conversion, to be offered on a competitive, unregulated, free-enterprise basis as companies choose, subject to carrier compliance with FCC-specified competitive safeguards.

In its 1982 Computer II decision, the FCC required AT&T to offer enhanced services through a separate subsidiary. After divestiture, that rule carried over to the new Bell TO companies, which found this requirement burdensome and sought its removal. The FCC reversed itself in its 1985 Computer III decision, agreeing with the Bell Companies and substituting nonstructural safeguards instead. It was here that the FCC first adopted the concept of Open Network Architecture (ONA) as one of the substitutes for the protection of fully separated subsidiaries, along with cost accounting standards and other regulatory requirements. It was here also that the FCC allowed RBOCs to offer Comparably Efficient Interconnection (CEI) as an interim measure until the approval of ONA plans.

ITAA took the view, as did most of industry outside of the Bell Companies, that the FCC had not established a basis for its policy reversal. The federal court reviewing the decision recently agreed, reversing that part of the decision as a matter of administrative law. Even so, the FCC is proposing to maintain the nonstructural safeguard approach in its latest Computer Inquiry proceeding.

While the ONA concept has merit, ITAA -- joined again by almost all of the IT industry -- has found the implementation to be quite lacking in many respects. Whereas full unbundling of TO services was originally held out as an ONA objective, substantial bundling in "feature groups" actually remains under TO ONA plans approved by the FCC. That is, to get one feature the enhanced services provider must take others in a package as well. As of this date, there is no known U.S. IT services provider ready to take the new ONA-mandated features under the ONA-specified prices, in many cases necessitating a four-fold increase in monthly rates. In ITAA's assessment, the nonstructural approach as administered by the FCC has provided ineffectual protection from anticompetitive activities by TOs, its disappointing implementation being added to its inherently lesser deterrent strength.

5.2 THE EUROPEAN COMMUNITY (EC)

While U.S. policy proceedings towards greater competition have lasted over the space of two decades or more, the forcing function of the EC's 1992 deadline for its unified internal market has created an urgent need for the EC Commission to struggle with these same issues. As part of its overall 1992 program, the EC Commission has issued six related policy proposals or directives:

- Telecommunications Terminal Equipment;
- Telecommunications Services;
- Associated Competition Guidelines;
- Open Network Provision (ONP);
- Satellite Services; and
- Government Procurement (including telecommunications).

The direction of all these instruments has been to move away from the traditional monopoly approach to the provision of telecommunications services and

equipment, and towards more open and liberal policies instead. ITAA and European users generally have welcomed this new policy direction by the EC.

The EC's approach to competitive safeguards is executed through the application of competition (antitrust) law in conjunction with the harmonization policy, Open Network Provision (ONP). The EC Commission's competition law authority resides primarily in Articles 85 and 86 of the 1957 Treaty of Rome establishing the European Economic Community. The Commission's ONP policy[17] seeks to harmonize, among the Member States, conditions for TO network access by IT services vendors. Member States and subject TOs must adhere to three competitive principles:

- make their decisions by an objective criterion;
- achieve "transparency" by publishing their decisions in an appropriate manner; and
- guarantee equality of access in a nondiscriminatory manner.

These ONP principles are intended to preclude most overt forms of anticompetitive activity by preventing the TOs from discriminating between providers (including their own affiliates) on the tariffs and usage conditions available for various network options. However, the EC Commission has acknowledged that there are situations in which the ONP principles may not protect against anticompetitive activities, such as cross-subsidization of competitive activities by the monopoly parent. For these and other circumstances where ONP does not constitute an effective safeguard, the Commission can apply competition principles directly.

Although competition law is inherently applied on a case-by-case basis, and thus is not enforced through a regulatory structure other than ONP, the EC Commission has published "Guidelines on the Application of EEC Competition Rules in the Telecommunications Sector" (26 July 1991). These guidelines offer advice on the general legal and economic principles followed by the EC Commission in applying competition law to the telecommunications sector. In essence, the EC's competition law (as embodied in Articles 85 and 86) prevents Member States from passing laws, or firms that are considered "dominant" from taking market actions, that fix prices, control markets, or discriminate against market participants. The guidelines describe the application of these principles to the provision of facilities and monopoly services, research and development, TO abuses of dominant position, and mergers and joint ventures.

Although the guidelines are not binding, their application through competition law will be enforced on a case-by-case basis. Thus, a clearer picture will develop of the EC's safeguard regime as harmonized ONP conditions are developed and implemented and competition cases are brought before the Commission.

5.3 JAPAN

The major landmark of modern Japanese telecommunications policy is the 1985 Telecommunications Business Law (TBL). Rather than distinguish between "basic" and "enhanced" services as such, that law chose to distinguish among firms, for legal and regulatory purposes, on the basis of facilities ownership and operation. Thus, the primary carriers such as domestic Nippon Telephone & Telegraph (NTT) and international Kokusai Denshin Denwa (KDD) are classified as Type I; all other firms, including value-added network services providers, as Type II. The Ministry of Posts and Telecommunications (MPT) administers a system of licensing for certifications to offer various services under this classification.

Japanese policy has evolved under a series of International Value-Added Network (IVAN) Agreements, the first of which was reached with the United Kingdom, and subsequent ones with the U.S., Canada, and France. In sum, although terms and conditions vary from one IVAN agreement to another, the agreements represent a significant step toward liberalization in the use of international leased circuits.

The latest step in Japanese policy began in March 1991, in the form of a special issues paper from MPT on "Measures to Ensure Fair and Effective Competitive in the Field of Value-Added Services." MPT stated a belief that, due to its review of Type I carrier charges for value-added services, predation would not be possible. New measures to be implemented are in the Accounting Regulation, effective for the 1992 fiscal year, such that Type I carriers will have to give separate profit-and-loss statements for voice (circuit-switched) and data (packet-switched) traffic, and for any "miscellaneous" service constituting more than 10% of the remainder. Furthermore, MPT promised that NTT would soon be offering its own network services and functions, now supporting its own competitive services, to Type II carriers as well; and that, in the future, such network functionality would be offered to Type II carriers at the same time as to itself. MPT said that the new competition policy would be subject to review within five years.

As to disclosure of technical information, MPT held that, while data for terminal connections had already started in 1990, it was requesting NTT to set up procedures for the dissemination of research and development results. Customer usage information disclosure measures remain the least developed safeguard. MPT announced that NTT had designated its own internally responsible body and established its own rules for in-house use, but there was yet no policy for release to other organizations. KDD has the entire matter under review.

5.4 OTHER COUNTRIES

Other countries have made substantial progress in liberalizing telecommunications services. Thus, they are progressing to the point where public policy discussions about competitive safeguards are meaningful.

5.4.1 CANADA

Canada relies on a mixed system of private and government telephone companies. The Federal Canadian Radio and Telecommunications Commission has adopted express definitions of monopoly "basic" and competitive "enhanced" services similar to, but not exactly the same as, the FCC's definitions in the U.S. The Canada-U.S. Free Trade Agreement was the first international trade document to incorporate trade in services obligations, including nondiscrimination requirements for "telecommunications-network-based

enhanced services." Moreover, Canada recently entered into one of a growing number of bilateral IVAN agreements.

5.4.2 AUSTRALIA

In 1990, the Government announced a package of liberalization measures, contained in legislation passed by Parliament in July 1991. The traditional domestic carrier, Telecom Australia, is to be merged with the international carrier, OTC (formerly Overseas Telecommunications Commission); and a private competitor will be established by year-end with full interconnection rights. The duopoly will last until mid-1997. In addition, the Government is seeking removal of current restrictions on both domestic and international resale, as well as the issuance of three public mobile telephone services licenses.

5.4.3 NEWLY INDUSTRIALIZED COUNTRIES

Hong Kong recently concluded a liberal IVAN agreement with the U.S., providing for essentially unrestricted use of leased lines, without punitive surcharges. **Korea** has been conducting bilateral telecommunications talks with the U.S. for several years. While Korea still maintains the principle that use of leased lines is restricted in general, it has been willing to ease some restrictions in practice and has publicly adopted the principle of network openness. **Singapore** has a telecommunications policy and practice that do not yet match its generally open and progressive overall economic and commercial policies, with national authorities not yet having embraced the concepts behind open network policies or competitive safeguards. **Taiwan** is pursuing an ambitious US$300-billion infrastructure modernization program. Liberalization and competition will become urgent issues as it faces decisions about how to build its telecommunications network for the future.

5.4.4 MEXICO, ARGENTINA, AND NEW ZEALAND

The privatization of previously state-owned telephone companies in these three countries is now making competition questions ripe in there. The North American Free Trade Area talks among the U.S., Mexico, and Canada will include negotiations over access to Mexican basic network services and facilities for U.S and Canadian IT services firms.

6. CONCLUSION

The emergence of competition between TOs and independent computer and information services vendors raises complex questions at the intersection of competition and telecommunications policy. The same ubiquity that allows the TO to provide desired services inevitably creates the ability and incentive for it to take unfair advantage of its less powerful rivals in competitive services. Options for regulatory safeguards, not all mutually exclusive, include an exclusionary rule; structural safeguards (fully separated subsidiary); resale; and nonstructural safeguards (accounting, regulation, information disclosure).

Debate may well center on the merits of structural versus nonstructural safeguards, or a combination of the two, with permissible resale possibly a part of either package. ITAA does not suggest that any one answer may apply to all situations. In light of political, economic, and cultural differences from one country and region to another, a good structure for one country may not be equally suitable for another. The objective in any event should be the promotion of competitive information technology markets through the restraint of TO monopoly power, however that objective is best achieved. in the context of each country's legal and regulatory system. That the International Chamber of Commerce, the world's leading business organization, has devoted so much attention to these issues underscores their importance in world economic growth.

Through the application of effective competitive safeguards, balance must be sought between the dynamism of entrepreneurial innovation, as reflected in competition policy, and the social objectives of diverse and geographically comprehensive services reflected in telecommunications policy and TO operating practices. This paper has sought to illuminate the nature of the choices and to delineate the wide range of informed approaches.

NOTES

1. Estimates by INPUT, Menlo Park, California, USA.

2. Estimate by International Data Corporation, Framingham, Massachusetts, USA.

3. This paper uses TO, in accordance with growing practice, as a neutral international term applying equally to franchised telecommunications enterprises regardless of ownership. The term PTT (post-telegraph-telephone), now in decreasing usage, has denoted government enterprises.

4. "Assurance of Fair Competition by Telecommunications Organizations," Position Papers Nos. 14-16, Paris, November 1990.

5. Resale, to be sure, refers to an action permitted to a user (in this case, an IT services vendor), rather than to one prohibited to the TO, the usual form that a safeguard takes. Inasmuch as resale does stop the TO from earning above-normal profits on its leased lines, and since it would be awkward to separate out resale from associated restrictive safeguards, this paper will speak of it as a safeguard. See Section III.D.

6. This particular case of network information involves the interplay of competitive equity and privacy or data protection issues. Generally, ITAA takes the view that, for data of this sort, a negative check-off or "opt out" option for subscribers suffices for their privacy interests, rather than the more cumbersome positive written consent. However one judges this issue, adequate data protection in no way justifies an asymmetry of access to subscriber data in favor of the TO to the disadvantage of independent IT services vendors. For a fuller discussion, see the related ITAA issue paper, "Personal Privacy and Data Protection."

7. These principles are expressed in accordance with U.S. accounting practices. Accounting rules must be tailored to be consistent with national accounting practices.

8. Terminology varies slightly. In the U.S., one refers to Open Network Architecture; in Europe, to Provision; in Japan, to Doctrine.

9. As a second best solution, if a TO insists on bundling (claiming, for example, that it is technically unavoidable), the the TO must be required 1) to use the bundled package in serving its own customers, and 2) to purchase or impute those service prices to its own competitive services at the same tariffed rates charged to all customers.

10. U.S. v. AT&T, 552 F.Supp. 131 (D.D.C. 1982).

11. RBOC has become the most common term for the seven companies thus created, called Regional Holding Companies by the Modified Final Judgment (MFJ) or Consent Decree, in distinction to the 22 Bell Operating Companies owned by them, who retained their names and service areas under the Decree.

12. See note 16 below.

13. As it does not represent long-distance or equipment companies, ITAA has formally remained silent about those particular restrictions.

14. "A basic transmission service is one that is limited to the common carrier offering of transmission capacity for the movement of information. In offering this capacity, a communications path is provided for the analog or digital transmission of voice, data, video, etc. information. Different types of basic services are offered by carriers depending on a) the bandwidth desired, b) the analog and/or digital capabilities of the transmission medium, c) the fidelity, distortion, or other conditioning parameters of the communications channel to achieve a specified transmission quality, and d) the amount of transmission delay acceptable to the user. Under these criteria a subscriber is afforded the transmission capacity to suit its particular communications needs." Amendment of Section 64.702 of the Federal Communications Commission's Rules and Regulations (Second Computer Inquiry), 77 F.C.C. 2d 384, 418-21 (1980).

15. A common carrier, at least in the common-law tradition, is one, either in transportation or communications, offering an essential public service and thus obligated to serve all customers and to do so equally, and to expand service capacity to meet the quantity demanded at its publicly regulated (sub-monopoly) price.

16. "For the purpose of this subpart, the term 'enhanced service' shall refer to services, offered over common carrier transmission facilities used in interstate communications, which employ computer processing applications that act on the format, content, code, protocol or similar aspects of the subscriber's transmitted information; provide the subscriber additional, different, or restructured information; or involve subscriber interaction with stored information. Enhanced services are not regulated under Title II of the [U.S. Communications] Act [of 1934]." 47 Code of Federal Regulations (CFR) 64.702(a) (1990).

In the Third Computer Inquiry, the FCC had made clear that protocol processing, in particular, is treated as enhanced and not basic: "The term 'enhanced service' shall refer to services offered over common carrier transmission facilities, which employ computer processing applications that act on the format, code, protocol or similar aspects of the subscriber's transmitted information; provide the subscriber additional, different, or restructured information; or involve subscriber interaction with stored information." Amendment to Section 64.702 of the Commission's Rules and Regulations, 2 FCC Rcd 3072, 3074 (1987).

17. Directive of 28 June 1990 on the Establishment of the Internal Market for Telecommunications Services Through the Implementation of Open Network Provisions, 90/387/EEC, Official Journal of the European Communities, L 192, Vol. 33 (24 July 1990).

NOTES

TELECOMMUNICATIONS DEVELOPMENT AND TECHNOLOGY TRANSFER IN TAIWAN, ROC

by P.Y.Lee
Director General
Directorate General of Telecommunications
The Republic of China

[Abstract]
Today , DGT is spending about US$ 2.3 billion every year for the network modernization and expansion of network capacity. The goal of building Taiwan as one of the financial centers in West Pacific is both logical and substantial. Through the heavy investment and managed efforts of technology transfer. Our goal will be realized by the end of 1996.

I. INTRODUCTION

Nowadays telecommunication is an integral part of people's daily life. Due to the effectiveness of network construction and operation, telecommunication provides people with speedy and convenient means for communication in both near and far-off distance. Taiwan, the Republic of China, is situated in the geographically strategic area in Asia. Based on our prediction about the future of this region, we deem it very important and practical to build this nation a telecommunication hub by enhancing our network construction.

We have also taken heed to another factor which will influence the future situation of Asia. Many people are quite concerned about the future and unpredictable impacts of Hong Kong after 1997. Aside from the probable political uneasy of the unstable economical prospects, a steady growth of economy and the attractiveness of financial resources must be preserved in this region whether the approaching unpredictable change of Hong Kong will happen or not. Building Taiwan as one of the financial centers in West Pacific to counter-balance the uncertain effects of 1997 is not only logical but substantial.

As we have set our goal and direction for the development of telecommunications, here I would like to focus my topics on the current development and the technology transfer in telecommunications in Taiwan, and taking this opportunity, to introduce our nation's "Six-Year Telecommunications Development Plan" which is designed to fulfill the above purposes.

II. CURRENT TELECOMMUNICATIONS DEVELOPMENT IN TAIWAN

1. Public Switched Telephone Networks

The popularity of telephone services can best represents the telecommunications development in Taiwan. Due to ever fast promotion of living standard and the economic prosperity of Taiwan in the past few years have stimulated significantly the demand for the telecommunications service. In order to cater for customer's demands and raise the network quality at the same time, DGT has not only devoted to modernize its plant facilities, but has also accelerated the digitization and optimization of the infrastructure of entire network. Currently the public switching telephone network is comprised of 3 primary centers, 15 toll centers and 1,032 local switching units. Among them, 92% of toll switching lines and 44% of local switching lines are digitized.

By September 1991, the number of subscribers has grown to 6.7 million and the telephone density has reached 32 main lines per 100 persons. We still remember the hard time of the early 70's, our growth rates were more than 20% annually, we had to double our plant facilities every 3 years. Even today, the growth is about 8.5% every year, is still higher than those countries with telephone density exceeding 30 main lines.

The investment in telecommunications in Taiwan has to rely on a self-supporting financial base and should be able to keep pace with the nation's economic planning and development. Today, DGT is spending about US$ 2 billion every year for the network modernization and the expansion of

network capacity. Special efforts have been made to generating revenues from new services.

2. International Network Development

To keep pace with the development of international trade and the rapid increase of people going abroad, as well as the growing interflow in international economics and culture, the International Telecommunication Administration (ITA), a subordinate organization under the Directorate General of telecommunications (DGT), has been engaged in the diversification, digitization and sophistication of communication satellite systems, optical fiber submarine cable systems, and international telephone and telex systems in recent years to upgrade the quality of international communications.

We have three standard A type satellite earth stations located in Taipei, and one brand-new satellite earth station located in the southern part of Taiwan. As satellite communication is going to digital as a world trend, ITA is gradually utilizing the most advanced communications facilities such as TDMA, IDR and IBS. We will set up two coastal stations to provide international maritime satellite communication services to the vessels sailing in the Pacific and Indian Oceans.

The technology of digital optical fiber submarine cable has come to maturity. Large capacity, long repeater span and high reliability are its major advantages. We have been directly investing in submarines cables through joint venture in Asian and Pacific region during recent years. These include the Asian-Pacific Cable, PACRIM-EAST, PACRIM-WEST, Australia-New Zealand No.2 cable, NO.5 Hawaiian cable, Burnei-Malaysia Cable, Brunei-Singapore Cable, No.4 Trans-Pacific Cable, No.2 Mediterranian Cable, and No. Se-Me-We Cable. At the same time, we have also procured the IRU to increase our traffic carrying capacity in the Atlantic Ocean. We believe that our communication facilities covering these three oceans will have enough capacity to accommodate the steady growing international traffic.

Today, we have a total of 4,709 direct telephone circuits and 752 telegraph, telex and data circuits to connect to 193 countries and regions. The growth rate of international telephone traffic was about 26% last year. In addition to the traditional Telephone and Telex, we also provide new services such as International free phone (I-800). International Operater Direct Connection (IODC), Store and Forward Facsimile.Since May 1989, we have provided the international video conference service to link Japan, USA, Hawaii, Singapore, UK and Hong Kong via IBS satellite circuits.

3. Data Service Networks

Data communication service plays and important role in Taiwan. DGT is responsible for providing public data communication service to the government agencies, private enterprise and the general public for their promotion of business operation, management and decision-making. We also provide the data circuit facilities to support the Value-Added Service providers to run their service. The Value-added Service has been liberalized to the private sector since in 1989 in Taiwan.

There are two packet switched data networks in Taiwan with 3 nodes located in Taipei, Taichung and Kaohsiung respectively. With a total capacity of 3,400 ports, there are 2,777 data subscribers linking by standard CCITT interfaces to the packet switched networks. Though our international gateway, subscribers enjoy the worldwide data-bank access. Taking this advantage, many subscribers set their firms and establish their global information centers in Taiwan. Last year, the growth rate of packet switched data services was 34%.

As computers overwhelmingly become part of our daily life in Taiwan, transfer of information becomes more and more imminent. The demand comes not only from business, but also from residences, not only in quantity, and quality but also in diversification. So the weighing of data communications services is expected to become heavier. To meet the diversified requirements we have established various data networks and provided the following data services:

- Leased data circuit
- Packet switching network
- Circuit switching network
- Chinese Videotex
- Public Information Processing Mail (PIPMAIL)

- Multi-Access Reservation Network (MARNET)
- Teletex
- Local Area Network (LAN)
- Public Information Process Service (PIPS)
- Mobile Vehicle Driver Network (MVDNET)

It is anticipated that the annual growth rate of data communications service in Taiwan will reach 30% in average. The ongoing network development will be focused on high speed processing, mass storage capacity and real-time transmission in order to promote the integration of computer and communications technologies.

4. Mobile Communications Development

Paging services and cellular mobile radio telephone are very popular in Taiwan today. For paging service the growth of paging subscriber is about 36% and the number of paging subscribers has reached 1 million. Both single-tone and display pagers are available in our paging system--the world largest paging system today which covers areas islandwide.

Mobile telephone is another rapid growing service in Taiwan. This service has opened in 1989 to meet with the requirement of the people-in-the-move. The service area covers three metropolitan areas of Taipei, Taichung and Kaohsiung as well as the area along the Chungshan Freeway, and it will be gradually expanded to cover other major cities of Taiwan. With a rocket-high rapid growth rate of 200% in the last year, now we have more than 210,000 subscribers today.

The mobile telephone system utilized in Taiwan today is an Advanced Mobile Phone System (AMPS) of North American standard. The urgent demand from subscriber pushes DGT to expand the system. Our next expansion project is to enlarge the capacity of the system to accommodate another 270,000 subscribers spreading over the whole island.

III. THE 6-YEAR TELECOMMUNICATIONS DEVELOPMENT PLAN

The telecommunications in Taiwan has made great advanced over the past decades. Our country has emerged on the list of fastest growing countries in the world in terms of telecommunications development. This is a mixed result obtained from the far-sighted development policy, the increasing demands of various sectors, the contribution of local telecommunications industry, and the endeavour of our colleagues.

Since 1980, in addition to the conventional voice traffic, the demands for data communication services has been growing rapidly. Such non-voice communication traffic will continue to boom up in the years ahead in parallel with the popularization of computers. To cope with the growth of the information oriented demands.

DGT has mapped out a "6-Year Telecommunications Development Plan" for the period of 1991-1996. In fact, this plan can be treated as a catalyst to transform ROC's telecommunications infrastructure into an intelligent and diversified one.

This plan includes the following 10 major construction projects:

- The construction of 10 million lines of local digital switches.
- Fully digitization of the toll switching systems in 1994.
- Mass construction of optical fiber transmission network.
- The construction of optical fiber transmission backbone along the Chungshan Freeway with a total length of 420 Km.
- The deployment of private circuit network with Digital Access Cross-connect Equipment (DACE).
- The construction of Taiwan-Matsu optical submarine cable to link Taiwan and off-shore island.
- Joint-venture to construct the Asian-Pacific submarine cable.
- The deployment of Personal Communication Network.
- The construction of Intelligent Network for providing services such as Call Card, Advanced Freephone, Mass Calling, Tele-voting and Virtual Private Network.

- The construction of ISDN for an early commercial use.

The total amount of capital investment in the next 6-year is about US$ 14 billion, and after the completion of the project, the digitization ratio of our local switching system will reach 92%, that will be the direct effect with such highly digitized infrastructure, we expect the ISDN service can be commercially interested in 1992 with a sound beginning of 1,000 users and reach 25,000 users in 1996, then gradually to become popular in the turning of next century.

IV. TELECOMMUNICATIONS TECHNOLOGY TRANSFER IN TAIWAN

The industry of telecommunications, as publicly recognized, has some characters, such as team work, intensive research and development, emphasis on maintenance and after sale service, and capital intensive investment. Especially when the advanced technology is a driving force behind the development of telecommunications service, such technology becomes not only costly to yield, but time consuming to reach its practical and commercial availability.

AT the end of 60's, DGT recognized that there existed a technology gap between Taiwan and some telecom leading countries such as USA, Japan and some European countries. In order to establish sound foundation for development of telecommunication technology, DGT set up the Telecommunication Laboratories (TL) in 1969. The mission of TL is to support DGT and its subordinates for the expansion, and improvement and modernization of the communication facilities and operating system so that more economic and high quality services can be provided to the public. By the turning of 80's, the goal of TL has been switched to "pave the way toward ISDN, both narrowband and broadband".

Currently, the resource allocated to TL is about 2% of DGT's revenue every year, which is about US$50 million. This founding is rather enormous, but can only support TL to conduct the R&D for the required technology to keep DGT's business running. It still unable to fill the long existed technology gap. A more effective and more efficient mechanism shall be implemented to save time for developing the leading-edge technologies. This approach is the technology transfer for the reason that transfer of technology has now become a very important business tool in today's fast changing and highly competitive world. In Taiwan, the technology transfer is a two-way approach, which has made notable effects and has reflected its advantages by higher technological level, larger system capacity, and better service quality.

For the technology transfer from overseas to Taiwan, 98 DGT employees were sent abroad to participate in the international conferences,symposiums and workshops in the past two years. At the same time, over 140 scholars were invited to come over to Taiwan and gave lectures of in different fields. To expedite the result of R&D, some licensed technologies and software were procured from foreign leading research institutes and companies. About 50 kinds of technical books, journals are also subscribed by TL to keep track of the most advanced development of telecommunications technology. In addition, joint venture of DGT with the three telecom manufacturing companies are still under way. These companies are AT&T Taiwan Telecommunications Inc., Taiwan International Standard Electronics Ltd. (TAISEL), and TAICOM System Limited. Through the joint venture, the advanced digital switching systems, such as AT&T's 5ESS, Alcatel's System 12, and Siemens EWSD (Taicom-5) have been manufactured in Taiwan with high percentage of local integration. Every year DGT procures from these manufacturers about 2 million lines of their switching system.

Moreover, a Science-Based Industrial Park was established in Hsin-Chiu, located in the northern part of Taiwan, in 1979 by government to encourage the return of overseas Chinese scholars and engineers to help set up high-tech firms in the Park. There are now 135 companies in the Park and 23 are engaged in the telecommunications-related activities.

As to the technology transfer from domestic R&D institutes to domestic industry, during the past decade from 1980 to 1990, DGT transferred many research results to the local manufacturers. The technologies have been successfully transferred to Taiwan's local manufacturers through 104 different contracts. Some of

the products have been put into service by DGT or exporting to overseas.

DGT has also enhanced the technology transfer through the mechanism of technology cooperation with local manufactures in the areas of System-12 Centralized OA&M System, Mini VSAT Network Operation and Management System, SONET Broadband ADD-Drop Multiplexer (ADM-600), Development of Optical AM Laser Link, Multi-channel FM-PSK Video Optical Fiber Transmission System, and ISDN PABX.

At present, DGT integrates the efforts of technology transfer and technical cooperation with local manufacturers and research institutes on the main topics of "ISDN CPE" and "broadband ISDN". This approach is aiming at the enormous market needs locally and abroad when ISDN and B-ISDN are going to be pervasively deployed in the coming years because the world trend are so obvious. Through the effective integration of the R&D resources, we will keep track of the world's technological development and winning our leading position in telecom hi-tech.

V. CONCLUSION

In the early 50's, only a small number of people in Taiwan were able to afford the telephone service. Today, you can find that about 92 residential households out of 100 have telephones to connect with all other telephones in every corner of Taiwan. We have witnessed the evolution that telecommunications have been contributed to creating the "economic miracle" in Taiwan. We still remember the "art" of how to make the best expansion of our telecommunications infrastructure with very scarce resources to benefit most to the national economic development. From this experience, we have the confidence that we can update our telecommunications to benefit the regional economic prosperity in Asian Pacific by the following ways:

- To increase the network capacity to meet the short-term and long-term requirements.
- To assure the network reliability to prevent the disaster due to communication interrupts.
- To reduce the network pricing to attract more users.
- To heavily invest on telecommunications construction projects to promote the prosperity of telecom/information industry.
- To provide swift telecommunication channels to assure better understaning of the governments and the people among the countries of Asian-Pacific.
- To market our dedicated services to fit those specific, and major customers.

The picture keeps in our mind is quite clear--- through heavy investment in telecommunications, many endless economic loops which bring countless wealth, will thus be generated in the way very similar to the nuclear chain-reaction. When the top priority was allocated to the telecommunications, and about 1.5% of GNP has been allocating to network construction, the great benefits to economic prosperity as well as leveling up the people living standards are predictable. It is hoped that our past experiences in telecommunications development, through the horizontal development of networks, and then to the vertical enhancement of services, which have been proved successfully in many occasions, will be applied today and tomorrow to make Taiwan a real contributing party of telecommunications hub in this region. We would like to have opportunities to share our experience with you !

Liberalization, Government Commitment And Telecommunication Performance: A Study of Telecommunication Sector Restructuring In Developing Countries

Nikhil Sinha
Department of Radio-TV-Film
University of Texas at Austin
Austin, Texas, USA

1. ABSTRACT

This paper presents the results of an empirical study of the impact of policy liberalization and increases in government commitment on the growth of telecommunications in 81 developing countries. The relative impact of these two trends is evaluated in terms of sector performance and distribution of basic telephone services.

2. INTRODUCTION

Telecommunications are increasingly being recognized as critical strategic infrastructure for ensuring the success of national social and economic development plans and programs, improving international competitiveness and integrating domestic economies into the world economy. New attitudes toward the economics of telecommunications and the role they play in overall growth and development are gradually being translated into stepped-up investments in the sector in many developing countries. In an effort to improve sector growth and development and overcome chronic deficiencies in telecommunication performance and distribution, many developing countries are engaged in revamping their sector policies.

However, there appears to be little consensus on the policies, regulatory mechanisms and sectoral arrangements which further the effective development of the sector. There are virtually no cross-national empirical studies of the impact of policies on the growth and development of the sector and few country specific studies of these issues. Despite this lack of research on the possible consequences of telecommunication policies on sector growth, many developing countries have been engaged in the process of sector restructuring. These changes have almost unexceptionably been directed at liberalizing the sector, where liberalization refers to the movement toward privatization and the introduction of competition.

This paper is motivated by the argument that sector policy changes may have significant consequences for telecommunications development. That the movement toward liberalized structures may not necessarily improve sector performance but may, on the other hand, adversely effect the conditions of access to and availability of telecommunications in many countries. This paper presents the results of a longitudinal cross-national study evaluating the impact of telecommunication policies in 81 developing countries on both the performance of their telecommunication sectors as well the distribution of services.

3. THEORETICAL DISCUSSION

The world telecommunications scenario has undergone dramatic changes in recent years. New information and communication technologies have transformed global and local economic activities. No country is exempt from the influence of this revolution. Reacting to these developments, governments, legislatures and regulatory bodies in most countries are engaged in re-evaluating the policies that govern the ownership and supply of telecommunication equipment, facilities and services with the aim of introducing private competition.

This drive toward liberalization is a marked departure from the policy framework which has governed the telecommunications sector in developing countries for a number of years. In the past, telecommunications was considered a good example of a natural monopoly, "an essential public good that governments should provide in a non-commercial mode" (Nulty, 1989, p. 7). Consequently, telecommunication services were provided by public enterprises under monopoly conditions. Changes in the technology and economics of telecommunications, it is argued, have eroded the condition of natural monopoly and the state monopoly structure is now increasingly being held responsible for the inadequate growth of the telecommunications sector in the past, and for its potential to hinder expansion and growth in the future.

The theoretical underpinnings of this drive toward liberalizing telecommunication policies are based on the many virtues of the market mechanism that have been detailed in neoclassical economics and which are being more or less vigorously embraced by a number of countries. Open competition and the relatively

unhindered operation of market forces, it is argued, will result in stepped-up sector growth and improved sector performance and efficiency (Saunders, Warford and Wellenius, 1983).

In short, the drive toward liberalization is based on the assumption that private competition may be the most appropriate mechanism for ensuring the growth and development of telecommunications. However, this belief in the ability of markets to foster the growth of telecommunications in developing countries, is not without its critics.

Raul Katz (1988) in his study of the information sectors in developing countries, argues that -- in contrast to developed countries where the development of telecommunications is the result of economic forces -- it is politics, rather than markets, that drives the growth of telecommunications in developing countries. There are two main reasons for this, the first concerned with sector efficiency, the second with sector equity.

First, despite the existence of some elements of competition, telecommunication markets in developing countries are far from efficient. Whether or not the sector is a natural monopoly, there do exist significant economies of scale which tend to be lost with the break-up of the public network. Additionally, the efficient operation of the market depends upon effective competition which is often difficult to achieve when economies of scale are large.

Second, markets usually deal inadequately with the provision of public goods or services like telecommunications. The market system works by putting a price on a service and the allocation of that service between consumers is made by their willingness to pay that price. When prices reach equilibrium it is assumed that demand for the service matches supply. This reliance on willingness to pay has obvious consequences for equity since, as Sen (1990) points out, "the willingness to pay also depends on the *ability* to pay" (p. 19; emphasis in original). Hence, even under conditions where competition can lead to improved sector performance and efficiency, it could very well lead to adverse conditions of distribution and equity.

Because of these dual shortcomings of the operation of market forces, particularly with respect to developing countries, Katz (1988) argues that "the expansion of the telecommunications infrastructure in most countries is a decision that pertains to political authorities" (p. 58). And the most effective instrument of governmental commitment to sector growth is the amount of resources it allocates to telecommunications. Pool (1963) argues that different investment practices may lead to the development of very different communication systems and, therefore, a major issue for most developing countries is how much of their resources to invest in communications.

Thus we see that in seeking to find ways to further the growth of telecommunications in developing countries we are faced with a number of competing approaches. On the one hand, there are those who argue that policy liberalization, characterized by the movement toward the introduction of private competition -- i.e., the operation of market forces -- may be the best solution for the problems of future sector growth and expansion. On the other hand, governmental control and commitment to sector growth, reflected in increased government investment in telecommunications -- i.e., the operation of political forces -- is also posited as an appropriate mechanism for telecommunications growth in developing countries.

At the same time telecommunication policies need to reconcile the possibly conflicting objectives of performance and efficiency with those of distribution and equity. This is an important issue since misplaced sector goals may run contrary to overall development strategies and objectives. In terms of both theoretical perspectives on the development process and empirical evidence of the role of telecommunications in that process, there is growing recognition of the need for balanced and equitable growth of the sector in developing countries.

Theoretically, the movement of thought in the disciplines of development economics and development communications has been toward underlining the importance of the distributional outcomes of development. The development economist Amartya Sen (1983; 1984) argues that the goal of development should be to enhance the capabilities of all individuals. Similarly in development communications, Kincaid's network-convergence theory (1988) and Krippendorff's theory of autopoetic development (1988) establish the importance of equitable access and availability of telecommunications to all individuals, communities and regions.as crucial to expanding their own potential as well as the potential of the societies in which they live.

Empirically, the importance of making telecommunications available to all sections of society is being increasingly documented. This ranges from case-studies of the introduction of telecommunications in different communities and their application in various sectors (Saunders, et. al.,1983; Hudson, 1981, 1984; Goldschmidt, et. al. 1982); through cost-benefit analyses of telecommunication projects to determine the rate of return on investments achieved by these projects (Kamal, 1981; Kaul, 1981; Saunders, et. al., 1983; Chu, et. al., 1985); to input-output analysis of the sectoral benefits of telecommunications (ITU, 1965, 1976; Lonnstrom, et. al., 1975; Kaul, 1979).

In short, it is apparent that regional, economic and social entities can play an important role in the development process, as long as they are provided the means and resources to fully participate in the lives of their nations. The role of governments, and by extension of the

policies governments formulate to govern various sectors like telecommunications, must be, therefore, to ensure that the conditions necessary for such participation are available and that no regional, economic or social entity is systematically deprived of access to those resources.

The preceding theoretical discussion suggests the following research questions which need to be addressed in an empirical study evaluating the impact of different telecommunication policies on sector performance and distribution:

1. What are the types of telecommunication policies existing in developing countries? How have these policies changed over the past decade?

2. What has been the pattern of government commitment to telecommunication sector development?

3. What are the patterns of telecommunication performance and distribution in developing countries?

4. Is there a relationship between policies and performance and policies and distribution?

5. Is there a relationship between commitment and performance and commitment and distribution?

6. Do these relationships hold after accounting for the level of economic development?

4. METHODOLOGY

4.1 Sample & Data

A total of 81 developing countries were selected for analysis after eliminating those with completely centrally planned economies and populations under 1 million in 1977. The study involved the analysis of secondary data which was collected from a number of different sources including the ITU's *Yearbook of Common Carrier Statistics*, AT&T's *World Telephones* and country reports maintained by the CCITT and the World Bank. The period under review was 1977 to 1988. More specifically, the impact of changes in policies and government commitment from 1977 to 1987 were examined in relation to changes in telecommunication performance and distribution from 1977 to 1988.

4.2 Variables

The research questions posed in the preceding section suggest four sets of variables involved in the study. The first set, the dependent variables, relate to telecommunications outcomes. The second, third and fourth sets, the independent variables, relate to telecommunication policies, government commitment and the economic factors that are thought to condition the relationship between policies and outcomes.

4.2.1 Telecom Outcome Variables

Telecommunication outcome variables (relevant to this study) are of two kinds: 1) variables measuring commercial performance and national level indicators, together referred to as *performance variables*; 2) variables measuring the conditions of availability and access to services, together referred to as *distributional variables*.

Performance Variables: The four main areas selected to represent improvements in telecommunication performance were: 1) expansion of basic telephone service, measured as the number of telephone lines per 100 persons; 2) improvement in network efficiency, measured as the average number of telephone calls completed per line per year; 3) demand performance, measured as the reduction of outstanding demand for basic telephone service; 4) improved financial performance, measured as increases in annual sector profits.

Distributional Variables: The two main areas for measuring availability and access were: 1) regional distribution, i.e, differences in the availability of, and access to, services between rural and urban areas and measured as the number of telephone lines per 100 persons in rural and urban areas; 2) the affordability of basic residential service, measured as the national average price of such service after converting to cross-nationally comparable international dollars (*World Tables, 1990*).

4.2.2 Telecom Policy Variables

The three main areas in which telecommunication policies were examined were: 1) policies governing the manufacture and procurement of telecommunications equipment; 2) policies governing the ownership of telecommunication facilities; 3) policies governing the supply of telecommunication services. The measurement of these variables involved the coding of policies, regulations and rules governing the extent of privatization and competition in each of these areas. Each variable was measured as the extent of competition and privatization permissible in each of the three areas on a ten point scale with 1 representing state owned and controlled monopolies and 10 representing private ownership and open competition, both domestic and foreign.

4.2.3 Government Commitment Variable

Government commitment to the growth of telecommunications was measured as the total annual government investment in telecommunications in each country, as a proportion of total annual government investment.

4.2.4 Economic Variables

The level of economic development is considered an important determinant of the growth of telecommunications. Per capita GNP is the most commonly used indicator of economic development in both economic and telecommunication studies and is used in this study as a control variable. GNP figures used here are those reported by the World Bank (*World Development Report, 1990*).

4.2.5 Research Design

The empirical analysis performed in this study was in three parts. First, *descriptive*, showing the state of the telecommunications sector in terms of policies, outcomes (performance and distribution) and commitment in 1977 and 1988. In the case of policies simple comparisons between measures at these two points in time would not be very useful in evaluating what is essentially a dynamic phenomenon. Therefore, using measures in 1977 and 1987 a policy change variable was constructed for each of the three policy areas -- equipment, facilities and services -- measuring both the recency and magnitude of policy changes through the following formula: $C = (M * T)/10$; where: C = average annual rate of change; M = extent of change from 1977 to 1987; T = number of years policy has been in place. The policy change variables were used in the analyses.

Growth rates were also calculated for government commitment and GNP/capita, in addition to comparing the state of the variables in 1977 and 1987. Here again growth rate variables rather than the single-point-in-time measures were used in the analyses.

The second, was *correlational*, showing the relationships between policies and performance and policies and distribution. The correlational analysis was designed to reveal whether or not changes in policies are significantly associated with changes in tele-communication outcomes. This analysis was further detailed by comparing the relationships between policies and performance and policies and distribution at different levels of national income: low, middle and high. Low income countries were defined as countries with with per capita incomes of less than $500. Middle income countries were those with GNP/capita between $500 and $5,000 and high income countries with GNP/capita over $5,000.

The third set of analyses were *multivariate*, estimating parameters of a regression model including both policy and economic variables. The regression model used in the study is a variation of the panel design. To capture the dynamic nature of policy developments as well as the impact of changes in economic variables, growth rates of policies, government commitment and GNP/capita (from 1977 to 1988) were used instead of static variables measured in 1977.

The final model was in the following form:

$$Y_t = a + b_1 Y_{t-1} + b_2 X_{ri} \ldots + b_n X_{rn} + e.$$

Where:

Y_t = dependent variable at time t

Y_{t-1} = lagged dependent variable

a = constant

b = unstandardized regression coefficient

$X_r i..X_{rn}$ = growth rates of independent variables

e = error term.

5. FINDINGS

Telecommunication sectors have undergone considerable changes during the eleven years spanned by this study. Despite financial and technical bottlenecks and rapid population increases, developing countries, as a whole, have shown improvements in most telecommunication outcome indicators. Table I compares summary statistics for telecommunication outcome variables (both performance and distribution) for 1977 and 1988.

Line densities (LinDen) have increased significantly over the period and traffic densities (TraDen) have also gone up. What is perhaps surprising is that demand performance (DemPer) has improved over the period with the registered demand for lines expressed as a proportion of existing number of lines being reduced by about ten percent. What is not surprising is that financial performance (FinPer) has worsened over the period. Whereas in 1977 profits were on average about 35% of expenditures, by 1988 they were registering an average loss of about 8%. Clearly, what was once a relatively profitable sector is increasingly becoming a financial burden in a number of countries (Nulty, 1989).

In keeping with the increased national level line densities, both urban (UrbDen) and rural (RurDen) line densities have shown improvements from 1977 to 1988. What is worrying is the significant increase in the average price (AvgPri) of basic residential service. The 1977 figure of about three international dollars per year represented from 8 to 12 percent of the average annual income of most people in developing countries, while the 1988 figure of almost five international dollars amounts to between 15 and 18 percent of average annual income. It appears that basic telephone service may be increasingly unaffordable in many countries.

Perhaps the most important assumption on which this study is based is that there have been significant changes in telecommunication sector policies, specifically those relating to equipment, facilities and services, over the period under study. These changes have been characterized as a process of liberalization encompassing the two axes of increased competition and movement toward privatization. In addition, there is also the presumption that

government commitment to the sector has also been stepped-up in many countries. Table II presents summary statistics for the three policy scales in 1977 and 1987 as well as the government commitment variable.

Clearly, policies relating to all three areas, equipment (EqPol), facilities (FacPol) and services (SerPol), have undergone liberalization over the period. Policies relating to the manufacture and procurement of telecommunications equipment were the most liberalized, even in 1977, and remained so in 1987. Service sector policies show a clear trend toward liberalization and there has also been movement toward liberalization in the facilities area. At the same time, government commitment to the the growth of the sector (Invest), measured as governmental investment in telecommunications as a proportion of total government investment, has also registered dramatic increases. There was an an almost five percentage point increase in investments in telecommunications from 1977 to 1988 providing clear evidence of the growing importance of the sector for developing countries.

While it is clear that telecommunication performance and distribution, as well as policies have undergone considerable changes over the period under review, are these changes related? The initial bivariate analysis of the relationship between policy change and performance suggested that policy liberalization is significantly related only to improvements in national line densities, while increases in government commitment are significantly related to improvements in line densities as well higher traffic densities and better demand performance

When these bivariate relationships were specified by levels of national income, the relationship between government commitment and performance remained consistent at all three levels of national income, low, middle and high. In contrast, the relationship between liberalization in the three policy areas and improved performance was significant only for high income countries.

Multivariate analysis further minimizes the impact of liberalization on performance. Table III provides the standardized coefficients of the regression of each of the four performance variables on the independent variables.

We note that there are virtually no significant coefficients for the three policy variables for any of the performance variables. In other words, after we account for the effect of the growth of GNP and the growth of government commitment, there are no significant independent effects of any of the liberalization variables. In contrast the government commitment variable maintains a significant independent impact on three of the four performance variables, underscoring the importance of the state for the growth of telecommunications in developing countries.

A similar step-by-step analysis was conducted for the distribution variables. The bivariate analysis revealed that liberalization of facilities, services and equipment policies are highly correlated with worsening conditions of access to and availability of telecommunication services. This is particularly true of the relationship between liberalization and increases in the price of basic residential service. In terms of the urban-rural divide, rural densities are negatively related to the three liberalization variables while urban densities are positively related to liberalization. In contrast, increased government investment in the sector appears to improve both rural and urban densities and is not related to increases in average price.

Specifying the bivariate relationships in terms of national income revealed that the deleterious effect of liberalization on rural densities and price of service is particularly acute for low income countries, while the positive impact of government investments is felt uniformly at all income levels.

The regression analysis confirms these trends (Table IV). The improvements in distributional outcomes from increased government investments hold even after controlling for the growth of national income and policy liberalization. Similarly, increases in price are almost entirely accounted for by liberalization in the three policy areas. The relationship between liberalization and poor growth of the rural network also remains significant after controlling for the growth of GNP/capita and government commitment.

6. DISCUSSION

The transformation of the telecommunications sector in developing countries, away from one characterized by state owned, controlled or operated enterprises, is significant. It appears that many developing countries are looking toward domestic and foreign private competition as the panacea for the many ailments of the sector. Perhaps the most remarkable development has been the liberalization of telecommunication facilities though changes in this area have more moderate and slower in coming than changes in the services and equipment sub-sectors. At the same time government commitment has increased significantly over the period under study, reflecting the changing perception that governments and international development agencies have of the importance of telecommunications for national development.

Of these two trends, one toward increased liberalization and the other toward stepped-up government investment, the latter is clearly a more important predictor of overall improvements in telecommunications performance. Increasing levels of government investment are particularly important for telecommunication expansion because of the relatively high capital requirements (Chapius, 1975) and high capital-output ratios (Huntly, 1967) that characterize the

sector. Traditionally, sectors with such characteristics, for example power, have tended to attract private investment mainly in distribution or re-distribution activities and rarely in infrastructural activities. This accentuates the saliency of government investment for sector growth.

Unlike liberalization of policies, increases in the proportion of government investment in the sector is associated with higher line densities at all levels of national income. Clearly, if developing countries are seeking to rapidly expand basic services, then the solution appears to lie more in stepping-up government investment in telecommunications, than in the neoclassical panacea of privatization and the operation of market forces. Indeed, governmental commitment remains an important predictor of network expansion even after accounting for the growth of GNP/capita.

With respect to distribution, again higher rates of growth of government investment are associated with improvements in access to availability of services in both rural and urban areas. In contrast, liberalization clearly leads to a worsening of distributional outcomes, particularly in terms of increases in the price of basic service and the retardation of the growth of the rural network.

Liberalization can lead to higher prices for basic service in three main ways. First, through the movement toward setting prices as close to cost as possible that is usually part of the liberalization process. This tends to eliminate the subsidies that are commonly in place for basic residential service and consequently tends to push up prices. Second, in a number of countries where sector policy liberalization involves the separation of urban and rural services, enterprises are able to take advantage of the outstanding demand for telephone service in urban areas by raising prices. Finally, as Saunders, et. al. (1983) point out, there could also be hidden costs incurred in sector liberalization in developing countries including inefficiencies associated with the loss of economies of scale through network fragmentation. It is quite probable that part of these costs are passed onto consumers.

Of equal concern is the opposite direction of the relationships between liberalization and rural and urban densities. There are three main ways in which sector liberalization can translate into improvements in network expansion in urban areas at the cost of rural areas. First, through the break-up of national monopolies into regional monopolies within the public sector. This enables those regional entities servicing urban areas to concentrate on network expansion and the reduction of outstanding demand without having to worry about transferring financial or technical resources to the more difficult to expand in rural areas.

Second, liberalized sectors are more sensitive to demand than traditional public sector monopolies. Though there is a large unmet demand for telephone service in many developing countries, this unmet demand is concentrated almost entirely in urban areas. Moreover, the demand for service is much more price inelastic in rural areas than in urban areas. Therefore, following these market signals, liberalized sectors tend to concentrate on expanding urban facilities to the neglect of rural areas. Third, it is probable that many services in rural areas may fail to attract private capital or suppliers. Liberalized sectors may be reluctant to invest in rural areas because sunk costs are high and returns low. Thus Walsham (1979) suggests that the expansion of rural service is dependent on either direct government subsidies of financing from out of the financial surpluses generated from urban subscribers and long distance services.

Developing countries, it seems, need to be particularly concerned about the impact of liberalization especially if keeping prices down and increasing rural penetration are national priorities. In contrast, increasing government investment may lead to the expansion of the basic network in both rural and urban areas, without prohibitive increases in the price of these services.

7. CONCLUSIONS

Dallas Smythe once wrote "Governments always, everywhere, intervene in the actions of their populations. The immediately relevant question lies in the answers their policies and actions give to the question: for whose benefit are they intervening?" (1986, p. 21). The findings of this study suggest that the liberalization of telecommunication policies in developing countries leads to a systematic worsening of conditions of access to and availability of basic telephone service with little corresponding gains in improved sector performance. If there are gains to be had from sector restructuring they may be realizable only under conditions of relatively high economic development and in countries with predominantly industrial economies. Perhaps more importantly, this study found considerable evidence that government commitment to stepping up the growth of the sector is the most important single factor in improving both performance and distribution at all levels of development.

There is, therefore, clear indication that if sector growth and development are important priorities for governments than attention should be turned toward stepping-up investments rather than sector restructuring. If sector liberalization is to be considered, then perhaps it would be effective only after certain levels of development have been achieved.

These findings are in keeping with an emerging body of literature which suggests that equitable development of many sectors in the developing world, including health and education, has been fostered mainly through the commitment of governments to sector growth and expansion. Many

620

countries that have relied on the market mechanism to foster growth have performed indifferently with respect to growth and worse still in terms of equitable growth (Sen, 1990).

Part of this problem arises from the fact that in developing countries, the market mechanism is inadequate for generating and equitably distributing a number of goods and services, particularly those that economists describe as public goods. Telecommunications, characterized by significant network externaliti, is, in many ways, a quintessential public good. Subjecting it to imperfect markets could prevent any possibility of equitable access to telecommunications in the majority of developing countries.

This study has attempted to evaluate the impact of telecommunication policies with an emphasis on the process of privatization and the introduction of competition that is underway in a number of developing countries. While much of the research attention has been focussed on the changes in the telecommunications sector in developed countries, this study has shown that a slow, quiet, but significant revolution in telecommunications policies is taking place in much of the developing world.

Virtually all reforms being considered by governments involve reduction in the monopoly control of the traditional telecommunications entity and some increase in the influence of market forces over operations and investments in the sector. The reasons behind these changes are manifold. It is believed that liberalization can overcome chronic deficiencies in investments in the sector, cope with the unmet demand for basic services, meet the needs of large users and expand the reach of the basic network. In short, liberalization is perceived to be the panacea for the many performance ills that plague the telecommunications sector in developing countries.

But, as the findings of this study show, liberalization of telecommunications has not been associated with significant improvements in telecommunications performance in the decade under review. As the global economy becomes increasingly integrated developing countries are looking increasingly for new ways to effectively participate in the global electronic marketplace. Telecommunications are now seen as electronic commodities essential to the expansion of national economies (Aronson and Cowhey, 1988). If this perception of the vital importance of telecommunications is to be translated into significant sector improvements, then liberalization may not be the solution. Instead, as already discussed, increased government investment may be the most effective means for significantly improving sector performance.

Efforts to improve sector performance through liberalization can also often lead to difficulties in striking a balance between considerations of commercial efficiency and social equity. Nulty and Schneidewind (1989) argue that in order to respond to growing technical and economic pressures, governments: "give their telecommunication systems greater autonomy and commercial orientation. But important national, social and economic interests will be jeopardized by the move to more commercial modes of providing telecommunications services" (p. 30).

In the traditional organization of telecommunications systems, these contradictions were reconciled directly within the single political body that both operated the telecommunications system and made social, national and economic policy: the government. But in the separation of telecommunications from government control and in the absence of effective regulatory bodies, the mechanisms through which the balance between equity and efficiency were maintained are sundered.

States thus play a two-fold role in the development of telecommunications in developing countries. On the one hand they are the prime sources of finances for investment in telecommunications. The extent of governmental commitment to the sector is the main predictor of the extent of sector expansion. In the second instance, governments provide the only existing effective domain within which competing interests can be reconciled and goals of balanced sector growth and equitable access and availability of services can be maintained.

While the focus of policy reform has been on improving commercial efficiency and sector performance, it must not be forgotten that telecommunications are important public goods with powerful consequences for the process of development. Distributional consequences are, therefore, an important component of policy evaluation. The negative impact of policy liberalization on the conditions of access to, and availability of services, could have grave consequences for national development plans and programs. Inability to access or afford services may result in the systematic deprivation of the potential to increase their capabilities (and, consequently, the conditions of their lives) for large sections of the populations of developing countries.

It is hoped that this study will provide evidence that will help in the evaluation of the telecommunication policies that developing countries have pursued in the recent past -- the impact of liberalization and government commitment on performance and distribution. And, on the basis of this evaluation provide guidance to policy-makers in these countries in selecting between the options available to them for reforming their telecommunication sectors and doing so in the context of their national economies and overall developmental objectives.

COMPETITION : A PATH TO NATIONAL AND REGIONAL COOPERATION

Australia

ABSTRACT

As much of the world moves into a new age of competition, Australia, too is undertaking a major restructuring of its telecommunications framework. The Government is instituting fundamental micro-economic reforms across the board, and introducing competition to what had been a public sector monopoly telecommunications provider. This paper addresses the nature and timing of these changes, looks at the processes and the players, and assesses some of the emerging outcomes.

1.0 THE CHANGING ENVIRONMENT

1.1 Globalisation

The world has continued to change markedly since Marshall McLuhan coined *the global village*. Easy access to reliable and affordable communications has not only shrunk much of the world but it has also given rise to typical village markets and competitive business practices. For some years now we have seen increasing internationalisation of businesses as well as changes in the nature of business. The huge demand for a wide range of communications products and services has given impetus to the development of new and exciting technologies and applications.

While this has yielded tremendous benefits to users and to manufacturers, it has also meant that the commercial life of technologies and applications has been considerably reduced. As a result, development has become a high risk/high cost activity, and the telecommunications equipment market has been increasingly dominated by a relatively small number of large global suppliers.

We have also seen standards take on new and critical meaning. Because of the rapid changes in technology and applications, the traditional standard-setting processes of the International Telecommunication Union (ITU) through the CCITT and the CCIR have found it difficult to respond to the pressures of the market place within a commercial timeframe.

As a result, *de facto* standards have emerged because of early market dominance and wide user acceptance. However, the increasing implementation of open systems has helped to unlock proprietary markets and created new opportunities for the smaller players and the specialist firm serving a particular section of the market.

While these outcomes may have introduced the character of a global village - complete with bazaar - they have also confirmed the dominance of export markets by the majors. On the other hand, because of the diversity of user needs within any particular market, the majors are beginning to recognise the valuable role that can be played by competent smaller firms in providing systems adaptation and integration to meet

625

the unique needs of the local market and to provide personalised customer service.

Globalisation of telecommunications, therefore, has brought with it a most interesting mix of competition and mutual dependence. The intriguing aspect of these changes is that few firms seem to have recognised that they have occurred.

1.2 The Australian Situation

For a country the same size as the United States with a population less than half that of California, given our geographic location and history it should be no surprise that the Australian situation is unique. Australia has a high standard of living, is a competent user of high technology and has a world class telecommunications network - which is as much due to necessity as to choice.

Providing reliable telecommunications services throughout this harsh continent to all Australians at an affordable cost is a tremendous challenge. The public switched telephone network is an essential asset to people living in remote homesteads and outback mining communities. It also provides a communications lifeline in times of natural disasters, such as during our frequent bushfires and floods, and tragedies such as Cyclone Tracy.

Internationalisation of business has also meant the internationalisation of competition and as pressures mount, so does the demand for a range of quality services and personalised customer support, at lower and lower prices. The same national PSTN that serves an essential community need, must also be responsive to the needs of business and provide world class access to the markets of the world.

There has been a popular perception that because it is a public sector monopoly, Telecom Australia could not deliver the lower prices and innovative new technologies required by business. Others believed that it was unresponsive to customer needs and was relatively inefficient on a world scale, being controlled by a powerful union protective of jobs. Telecom used to employ about 86,000 people.

In the May 1988 Economic Statement the Government announced a new framework for telecommunications in Australia. It also embarked upon a bold program of micro-economic reform across its transport, maritime and aviation sectors. It made sweeping changes to the Telecommunications Act, created a separate regulatory body (Austel) and foreshadowed further liberalisation of the telecommunications environment. With the rapid and severe deterioration of the world economy, however, the Government was again faced with decisions on the telecommunications sector.

1.3 Government Decisions

The Government believed that new attitudes were required in the industry, to be under-pinned by vigorous competition, if Australia was to survive and prosper in the international telecommunications market. On 8 November 1990 it announced a number of decisions which significantly extended the impact of its micro-economic reforms.

The key decisions announced by the Minister for Transport and Communications, the Hon Kim Beazley MP, provided for the following initiatives:

- the establishment by the end of 1991 of a private sector competitor to a merged Telecom/OTC;

- the introduction, as soon as practicable during 1991, of full resale of domestic and international telecommunications capacity;

- the issuing of three public mobile telephone service (PMTS) licences including one to AUSSAT prior to its sale and one to Telecom/OTC;

- the introduction of full competition in the provision of public access cordless telephone services (PACTS);

- consideration of further PMTS licences in 1995;

- carrier competition to be limited to the duopoly until 30 June 1997.

In a subsequent speech on 4 March 1991 the Minister noted that in promoting competition and dynamism in the telecommunications industry, the Government wanted to position Australia to take advantage of new export and job opportunities that will be created around the world, particularly in the Asia-Pacific region. The Minister also reaffirmed the Government's wish to maintain Telecom and OTC in full public ownership and to ensure maximum possible Australian ownership of the telecommunications industry.

The Government saw network competition as the driving force for achieving its policy objectives. It envisaged across the board competition between the two carriers in both the domestic and international markets. AUSSAT would be freed of its restrictions from competing fully with Telecom/OTC and sold to form the basis of the second carrier which would have majority Australian ownership within five years.

In relation to industry policy considerations, the Government decided that both carriers would be free to choose and exploit technologies of their choice from around the world. However, the licence conditions of both carriers would provide for commitments to technology transfer, local research and development, local sourcing of equipment, and exports of locally developed products.

In defining its policy framework, the Government articulated 83 separate decisions, covering areas such as:

- competitive safeguards over the abuse of market power by Teleco/OTC as a result of its established presence in the market;

- arrangements for interconnect and access to the Telecom network and ancillary facilities;

- charges for interconnect and access;

- accounting separation of the activities of the second carrier and Telecom/OTC;

- price capping arrangements (*CPI-x*) for the dominant carrier Telecom/OTC to encourage productivity improvements and prevent predatory pricing;

- maintenance of Community Service Obligations (now called Prescribed Carrier Obligations) particularly to rural and regional areas, pensioners and people with disabilities;

- end of the First Phone monopoly on 30 June 1991; and

- provisions for the merger of Telecom and OTC.

The Government's decisions were laid down comprehensively in legislation. The Government also strengthened and enhanced the role and powers of Austel as an independent regulatory body to cover technical regulation, promotion of fair and efficient market conduct, protection of customers and the

achievement of industry policy objectives. Austel was also given a specific mandate to promote competition within the regulatory framework established by the Government's decisions.

2.0 COMPETITION

2.1 The Australian Identity

Such major changes coming on top of the changes promulgated in the May 1988 Economic Statement surprised many in the industry. After all, the revised *Telecommunications Act* and the Corporatisation of the Government Business Enterprises (GBEs) were less than a year old, and for years the tradition of telecommunications reform in Australia has been *steady as she goes.*

The way in which the changes were introduced indicates something about the Australian identity and, indeed, about this particular Labor Government. The package comprises an interesting mix of reliance on free market forces and, to make sure that they actually work the way they should, a bundle of supporting legislation and regulation. It clearly demonstrates the art of liberalisation, or deregulation through re-regulation.

The timetable that the Government set for achieving the changes was nothing short of breathtaking. No doubt the tight timeframe imposed on the proceedings owed much to internal party political considerations and to the Federal elections to be held in 1993.

However, while it would be easy to be critical of the rush, there is much to commend the Government's fortitude for sticking to its guns and driving both the public sector as well as its own internal political processes to ensure that the planned outcomes could be achieved within the timeframes it had set.

The problem confronting the Government was how to quickly change the culture, orientation and operations of a very traditional public sector PTT to a market driven, customer responsive, innovative telecommunications organisation operating essentially on commercial principles.

Unlike some other countries, the Government had made it clear that while it supported restructuring and liberalisation, it would not tolerate a *slash and burn* approach. The changes would need to take account of Australia's unique position and the Government's commitment to the achievement also of social objectives in the public interest.

It recognised also that the Australian telecommunications industry had grown up around Telecom and, by and large, embraced the same traditional PTT culture and attitudes. As the supporting industry would need to be an integral part of the restructuring, it too had to become even more competitive if it were to be able to operate successfully in the new environment.

Faced with these considerations, it could be argued that the imposition of a short, sharp shock would act as a circuit breaker, without causing undue and long term disruption to the industry. Because of the importance of the changes and the tight timeframes imposed for action, all concerned parties would have little option but to focus on getting the best positive outcomes within the parameters presented by the Government. To date, that strategy appears to have worked.

2.2 The Second Carrier

That AUSSAT should be offered for sale as the core of the second carrier has caused much debate. At various times it has been described as a "lemon" or an "albatross" for the Government. Various statements have been made about AUSSAT's

$740 million debt, implying that this is the extent of "wasted" taxpayers' money.

While such statements catch headlines and are easy to understand, they are also incorrect. By far the greatest part of AUSSAT's "debt" is normal private sector leverage leasing arrangements to cover payments for the replacement B-series satellites planned for launch in 1992. The Government has agreed to discharge the totality of AUSSAT's debt on its sale.

AUSSAT is a public company in which the Government is the sole shareholder. It is required under its Memorandum and Articles of Association to operate as a commercial, taxpaying enterprise, subject to certain public interest provisions. Most importantly, it has been prevented (until recently) by policy and legislation from competing directly with Telecom for the services it provides, and from engaging in international traffic.

Given the restrictions under which it has had to operate, the results that AUSSAT has been able to achieve are remarkable. AUSSAT has established a wide range of customers, principally in the broadcasting sector, and made possible a new range of services to people in outback and under-served areas as well as to downtown hotels and to clubs. It has also successfully planned and negotiated world-wide contracts and arrangements for the replacement B-series satellites, which embody leading edge technologies.

In presenting AUSSAT as the nucleus of the second carrier, the Government is privatising a valuable asset with an established customer base. AUSSAT also has many experienced professional staff who know and understand the operations of Telecom and OTC extremely well - most of them came from there!

3.0 CARRIER SELECTION

3.1 The Selection Process

The selection process for the second carrier licence (and also for the second mobile licence) was the sale of AUSSAT. In the early days leading up to the process there had been a number of wild guesses at the appropriate level of licence fee. Some argued figures of around $1500 million, while others had equally expansive figures on the potential worth of OTC when it was thought to become the core of the second carrier.

Such speculation obviously caught the attention of the cash-strapped Government, which anticipated a generous second carrier licence fee, as well as expecting Telecom to pay a fee to the Government for the acquisition of OTC to become the merged Telecom/OTC.

The Government established a Second Carrier Selection Team comprising representatives from a number of Federal Departments to administer the selection process and advise the Minister. It invited initial expressions of interest on 5 December 1990 and foreshadowed a staged process through firm proposals to requests for tender, to be completed by December 1991. Another task group was established within the Department of Transport and Communications to be responsible for the Implementation of New Carrier Arrangements (INCA).

Perhaps the most difficult task was sustaining and supporting on-going consultation with the industry and potential stakeholders. The timeframes were already tight, and the time that could be made available for outside parties to consider and comment on draft legislation and conditions was necessarily short. However, the consultative process was essential for bringing about a result that would work. By involving all parties in the process,

any difficulties could be identified at an early stage and, where possible, agreed solutions achieved.

3.2 The Selection Criteria

The Government's principal objectives to be achieved through the second carrier are to improve the standard and range of telecommunications services, and to reduce costs to consumers both residential and business.

The Government also announced that in assessing proposals, it would attach particular emphasis to the following criteria:

- the ability and commitment of potential investors to compete effectively in the Australian telecommunications environment;
- the financial strength and managerial capabilities evidenced in the proposed corporate entity, and a proven track record in planning and operations in the telecommunications field;
- commitments to bring tangible benefits to Australian industry, through technology transfer, contributions to Australian research and development, local manufacturing opportunities and support for exports of products and services;
- arrangements for achieving majority Australian ownership of the second carrier on a planned agreed basis within five years;
- price and related payments, although these would not be the sole determinants of selection.

The RFP sought innovative proposals from prospective bidders for AUSSAT which addressed the above criteria and detailed how their proposals would lead to development opportunities for Australian industry.

3.3 Industry Policy Considerations

One of the issues that was given considerable attention throughout the selection process was the strength of the Government's commitment to industry policy arrangements. What should have been a relatively clear cut issue became clouded by much uninformed debate.

There was a perception that because the Government had adopted economic rationalism and competition through free market forces as its approach to the economy, it was not serious about the industry policy requirements for selection of the second carrier. This caused concern to Australian firms, who considered that without the commitment of the major players, they could be locked out of local network development or denied access to regional markets dominated by the majors, irrespective of the quality of their products and services.

The Government established a Ministerial Advisory Committee (the MAC), chaired by a prominent Parliamentarian, with a number of expert advisers drawn from various sectors of the industry to consider and advise on a range of industry issues.

4.0 STRATEGIES AND ALLIANCES

4.1 The Emerging Players

In response to the Government's advertisement in December 1990, over thirty expressions of interest were received. None of these was announced, but various players became public during the process and the Government welcomed such keen competition for the second carrier licence. It was known, for example, that a number of the RBOCs and major European telcos were among the contenders.

As the process moved into the second stage in March, however, there were a number of departures from the competition. Among these were Nynex and British Telecom, whose withdrawal created much speculation in the industry. Some argued that in seeking a high licence fee and making AUSSAT the centre of the second carrier, the Government was making the game too tough. Others claimed that there were few credible bidders left in the race and the Government could not sustain effective competition for the carrier licence.

There was much speculation about which firms were left in the race and what their chances were likely to be. The presence of major Australian industrial and financial companies also created interest. Ameritech and Bell Atlantic, fresh from their triumph in New Zealand, were rated highly, as were BellSouth and Cable and Wireless.

4.2 Competition and Cooperation

It was an exciting time in Australia! Everyone was courting everyone else (or others claimed they were) as the pace hotted up. It was not long, however, before two consortia emerged - an American led group with the Aboriginal name Kalori, and a US/UK alliance with the unfortunate acronym ACE (Australian Communications Enterprise).

The Kalori group comprised Ameritech and Bell Atlantic, together with the Hong Kong based Hutchison Whampoa. ACE comprised BellSouth and Cable and Wireless, and several major Australian investors including Mayne Nickless, AMP, National Mutual and the AIDC. While names such as Bell Canada and AT&T were mentioned, they could not be tied to any consortium.

The campaigns conducted by Kalori and ACE were very different.

BellSouth continued its high profile activities and initiated wide-spread dialogue with Australian industry. It was open about its plans for network competition and in effect invited "tenders" from Australian firms for the inputs they could provide. In this way ACE sought to demonstrate that they were serious about industry policy and had a number of Australian firms already "signed up".

By comparison, Kalori made few public statements. No doubt it was making its *due diligence* inputs to the Second Carrier Selection Team, but it was losing the war of words and lacked public visibility. Its plans, other than for mobile, were held close to the chest. It did not seem to appreciate the importance in Australia of maintaining a positive image of the consortium before politicians and the public.

Some have argued that this was really a strategy to have contenders under-estimate the Kalori bid, while they quietly presented their winning case to the Government.

4.3 Strategic Alliances

While the major competitors for the second licence sought to position themselves with the appropriate mix of joint venture partners, the smaller industry players were also taking a hard look at market opportunities both in Australia and in the Asia/Pacific region.

It was too early to pick winners, but the firms noted that the members of both ACE and Kalori had considerable leverage in the regional markets. While it was very attractive to "sign up" with one or the other, the risks of exclusivity were obvious, including the potential reaction by Telecom, their existing major client who would remain the dominant purchaser for some years.

The keen competition proved to be a catalyst for the more entrepreneurial Australian firms. Looking beyond

the second carrier, they saw the need to be aligned with a major world class supplier who complemented their capabilities and had access to regional markets and new technologies. By remaining neutral, they could retain their existing favourable supplier status with Telecom, while presenting themselves to ACE and Kalori on their merits, hopefully with a major world supplier lending weight to their claims.

An excellent example of regional cooperation was the forging of a strategic alliance on 13 June 1991 between Exicom Limited, Australia's largest domestically owned telecommunications and electronics manufacturer, and the international telecommunications giant Northern Telecom Limited. The alliance positioned NorTel Australia Pty Limited, Northern Telecom's local subsidiary and Exicom to take advantage of the rapid changes in Australia and in the Asia/Pacific region.

Both companies are targeting initial joint manufacturing and marketing initiatives to yield at least $10 million in exports in the first year. The partners are establishing an Australian Development Centre at Exicom's modern manufacturing facilities in Sydney, supported by a technology transfer program from Northern Telecom. The Centre will provide specialist local development and adaptation of NorTel products to meet the stringent requirements and standards of the Australian licensing authorities, the carriers and resellers.

The focus of the initiative is on both developing a comprehensive manufacturing base for NorTel and establishing the required level of customer service and support, drawing on a base of technological excellence and strict quality assurance. The Centre will apply its research and development capability to extend the range of Exicom and NorTel product packages, with a particular focus on leading edge technologies to meet the specific and often unique needs of regional markets.

This alliance has been a positive response to the changes in the telecommunications environment. It has been well received by the Government and the major players, and should provide long-term benefits to both firms.

4.4 Industry Arrangements

For many years Telecom Australia had encouraged the development of the Australian telecommunications industry under its local sourcing policies. Given Australia's geographic location, population distribution and relatively advanced economy, such support owed as much to enlightened self interest as to national pride. The result has been a small but efficient telecommunications industry well versed in advanced technologies, with particular skills in developing and adapting overseas equipment and software to meet Australia's unique needs.

Firms were concerned, however, that the imminent pressure of competition from the second carrier could force Telecom to pursue a "lowest price" purchasing philosophy. They also recognised that unless some constraints were placed on the consortium of overseas players that would control the second carrier, transfer pricing could result in equipment being supplied internally from the corporate giants overseas. Similarly, because of the dominance of regional markets by the majors, access to export markets could be extremely difficult.

Leading Australian firms co-operated to formulate industry policy arrangements for the period of the carrier duopoly until 1997 and beyond. Considerable consultation was involved and the views and fears of key Government Departments and Ministers were taken into account.

The arrangements were built on commercial principles rather than on protectionist lines, while ensuring that Australian firms would be given the opportunity to compete.

The resulting policy generally met with the approval of all key players. It was also very similar to the industry development arrangements formulated by the MAC.

5.0 THE SECOND CARRIER

5.1 The Final Bids

The timing for the selection of the second carrier was extremely tight. Several streams were pursued in parallel to ensure that the legislative backing was in place to support implementation of the decisions. Decisions by Austel were also awaited on issues such as the price of interconnect and the associated arrangements. Nevertheless, firm proposals were invited on 26 March and, despite various withdrawals, on 31 July two consortia were invited to make their final offers.

The reduction of competitors from over thirty to two could have been embarrassing for the Government had it not been for the impeccable qualifications of the contenders. ACE had been quietly re-named Optus Communications, which it was explained came from the Latin *I choose* (and not "opt US" or "opt us"). It was rumoured that Kalori was soon to gain yet another large and powerful partner, although guesses ranged from AT&T to Bell Canada, and that British Telecom would re-enter the race.

The third contender to lodge a bid in early July was COMSAT. However, the Government did not believe it appropriate for COMSAT to be shortlisted, because its proposal addressed only satellite technology applications. It suggested that COMSAT would be free to pursue its ideas with Optus and Kalori.

Final offers were due by the end of October. Optus widely canvassed industry participation possibilities and sought to respond to the weight of paper presented to the competing consortia by the Second Carrier Selection Team. There was much debate about the real value of the licence fee and indeed of AUSSAT, particularly as to how this would affect Australia's ability to leverage an acceptable return for its sale.

Many argued that AUSSAT would be more attractive if the Government agreed to Pay Television. The first time around it was rejected by the Caucus, but as the competitive edge wavered, the Government gave the go-ahead for Pay-TV on 9 October (at least in principle) and reserved the national license for satellite delivery via at least four AUSSAT channels. The push had been from some quarters for optical fibre cable delivery by Telecom.

This was seen by many as a means of trying to make the AUSSAT sale more attractive, but at that time dire rumours were circulating. Despite the addition of France Telecom to the team, the imminent collapse of the Kalori consortium was reported in the *Australian Financial Review* on 22 October. The news was confirmed on 24 October in a press release by Ameritech, Bell Atlantic and France Telecom. They advised that the decision resulted from a realisation that the final business plan developed by the Kalori consortium was not a strategic fit with their companies' investment criteria.

The interesting outcome was that Hutchison decided to pursue the bid on its own as Kalori. It also announced an alliance with AT&T and an Australian link through AWA.

Meanwhile, Optus had announced NorTel as its primary switch supplier, Nokia for GSM mobile and Exicom as a key Australian supplier and systems integrator. It was also quite open about its network rollout plans and employment strategies.

5.2 The Decision

Both Optus and the modified Kalori submitted their final offers early in November. The bids were quite different, with Optus offering fixed links to provide network competition, and Kalori stressing wireless links and reliance upon the existing optical fibre network capacity of Telecom to avoid "wasteful" duplication.

By 19 November it was all over. The Government announced that it had selected Optus to be the second carrier. Optus would pay to the Government a total of $800 million (which would nicely cover AUSSAT's debt and leverage leasing arrangements of $740 million which the Government had agreed to discharge on sale) and invest almost $2000 million over the next six years in the network. Optus also committed to achieve 70% Australian content in its capital investment in equipment supply and installation. It expected that over the next five years 5000 jobs would be created, with $100 million committed to training.

Because of its Australian joint venture partners, Optus would have 51% Australian ownership from the outset, exceeding the Government's requirement to achieve majority Australian ownership after five years.

The Government expects contractual documentation to be finalised in time to enable completion of the transaction on schedule by 31 December 1991 as planned. The overall effort over such a timeframe is remarkable and a credit to all participants, including the industry players who had to drive very hard to meet the tight and continuing deadlines.

6.0 UNFINISHED BUSINESS

6.1 Competition

Network rollout will be rapid. Long distance and international services are expected to start from Sydney in late 1992. A competitive mobile telephone service will begin in early 1992, using resale of air time on the present Telecom analogue MobileNet system to establish market presence. It will be some time, however, before practical assessments can be made about the benefits of competition.

The industry policy arrangements for which the leading firms fought hard to achieve will be reflected in the licence conditions for the carriers, which will have the force of law. However, because this requires amendments to legislation, the statutory process would have left the amendments tabled and subject to disallowance by both the Senate and the House of Representatives for fifteen sitting days. This would have deferred the licence conditions into 1992.

To overcome this potential difficulty, the Government simply moved an amendment changing the statutory time from fifteen days to five.

The Government made what was thought to be a "brave" decision in selecting GSM for the digital mobile telephone technology to replace the existing analogue systems. With the rapid changes in technology, some are already asking whether GSM has already been passed and are we not into the realm of PCN. This will have interesting implications for competition in mobile services, particularly as the Government has re-affirmed that expressions of interest for the third mobile licence will be invited in early 1992, with service expected to begin in 1993.

6.2 Regional Co-operation

The introduction of the processes leading to competition have already had a considerable effect in forcing Australian firms and their strategic partners to take a wider view of their market opportunities. Some have started to position themselves not

only to deal effectively and competitively with the carriers, but also to focus on export opportunities in regional markets. One of the challenges is which products? and which markets?

The growing commercial importance of telecommunications has forced even the larger players to take the implications of globalisation into account in their planning and marketing. In the '90s we have seen individual competition give way to co-operation in the pursuit of markets. While there are still opportunities for smaller firms to capture niche markets, the increasingly high cost of proving technology applications provides a strong incentive for co-operation so that costs and risks can be shared.

Contrary to popular past perceptions, regional markets are fast becoming more challenging. As economies develop and the population becomes more demanding and discerning, it takes skill, understanding and patience to establish a lasting market presence. While the large global players have established markets around the world, their very size makes it difficult and expensive for them to configure their products to meet particular local needs.

It is in these situations where the capable smaller firms are able to create new opportunities. Their greater flexibility and often regional understanding complement the access to technology of the global firm and the corporate resources it can make available. Such symbiotic relationships in the decade of the '90s herald the era of competitive co-operation.

Handled sensitively, competitive co-operation can unlock a wealth of alternative futures for the emerging nations of the Asia/Pacific region. In establishing such arrangements, Australia is already playing a leading role.

Restructuring of the Global Information Industry and the Resulting Demand for New Skills

Una Mansfield and Richard A. Joseph
Information Technology and Communication Unit
Faculty of Informatics, University of Wollongong
Wollongong 2500, Australia

1. ABSTRACT

The ongoing restructuring of the information industry affects a wide range of constituencies. Good models are needed to guide our understanding of the relationships among industry sectors; existing models are discussed together with suggestions for an alternative approach. Issues relating to the appropriate education and training of the workforce needed by the restructured industry are raised.

2. THE INFORMATION INDUSTRY

2.1 Convergence and Competition

The 1990s are providing unprecedented opportunities--and risks!--for telecommunications organisations. Many of those that have enjoyed virtual monopolies over a well-defined set of products and services are facing competitors in established markets and the challenge of capturing new markets for hybrid products and services based on converging technologies.

And the field is rather crowded. As Jonscher (1) points out, enhanced information processing functions to support new products and services can, in many cases, be provided equally well by computers and intelligent terminals *or* by value-added systems *or* by transmission links and switches. This leads not only to competition among various types of firms in the computing field but to a new level of competition between computing and telecommunications. With the advent of digital audio, whose transmission system may be merged with other digital communications streams, broadcasting also enters the picture.

We believe, therefore, that the strategies for capitalising on the new business opportunities will be more effective if telecommunications is regarded as an integral (albeit the largest) part of a broadly defined information industry whose primary sectors--*telecommunications*, *computing*, *broadcasting* and *publishing*--are becoming more integrated at the level of technology but more competitive at the market level.

We aim to explore this convergence and competition in our paper, and to point to the need for good maps and models of the information industry to guide strategic decision-making.

2.2 Constituencies Affected

Many constituencies stand to benefit from a clearer understanding of the evolution, structure, regulation, activities, relations among and economic importance of the various sectors of the information industry. Apart from *telecommunications organisations* themselves, these include:

economic planners, who see the information industry not only as a dynamic activity in its own right but as a core industry that enables others to develop and, therefore, as a catalyst for economic growth;

national and regional governments, who must make public policy on indigenous information-industry development and regulation, as well as on the control of national and international information flows;

international organisations, who represent the social, political and cultural views, as well as the economic interests, of their constituents in relation to the "new world information order" (a UNESCO phrase);

transnational corporations, whose operations depend on the unimpeded flow of corporate data through international public and private networks;

service industries, who see in the application of new information technologies the potential for big increases in the tradeability of their services (banking, insurance, marketing, etc.);

production industries, who look to such new technologies as CIM (computer-integrated manufacturing) for productivity improvements to render or keep them competitive;

information-industry entrepreneurs, who control a major growth industry, which also provides the infrastructure and services that enable other industries to develop;

information professionals, who possess the expertise on which the information industry depends for research, development and applications, and who need to be able to plan careers that could involve mobility among the various industry sectors; and

educators, who must understand the dynamics of the information industry so that they can maintain curricula that give graduates and trainees knowledge and skills that are relevant in a constantly changing marketplace.

3. THE FORCES OF CHANGE

3.1 Market Factors

Some of the forces that are bringing pressure for restructuring of the information industry are also affecting other industries at this point in history.

They include: globalisation of markets and production facilities via the establishment of transnational or multi-domestic corporations; the concomitant push for liberalisation of world trade, as overseen by such institutions as the GATT (General Agreement on Tariffs and Trade); the emergence of powerful regional trading blocks, such as the 12-nation European Community, which enable nations to trade in markets much larger than their home bases and give them strength in numbers in their dealings with other regions; plus a spate of mergers and takeovers by companies seeking to take advantage of the "economies of scale" offered by global trading.

Other forces are peculiar to the information industry: they include the continuing pressure for re-regulation of telecommunications and broadcasting; and changes in the relative world market values for individual communications versus mass-communications, where declining computing and networking costs have rendered the former competitive with the latter and opened up a whole new slate of opportunities for both buyers and sellers.

3.2 Technological Factors

The single most important technical influence on information-industry restructuring is the digitisation of all the forms of information representation (voice, video, data, images and text) which permits information that formerly was carried separately (e.g., voice traffic by telephone companies and video traffic by television companies) to be handled in common with all other types of information. Thus, according to a recent OECD (Organisation for Economic Co-operation and Development) report (2), technology is becoming of less importance as a limiting factor constraining innovation. Instead, "it is other factors, such as pricing, quality, marketing, and the level of demand which determine the success of new products and services." Each of the industry sectors must recognise that its technology no longer necessarily gives it an exclusive advantage over competing sectors in specific applications.

The implications of technological convergence are far-reaching. Armstrong (3) speaks of "services which can leap the existing legislative boundaries"; and problems arising from the existence in many countries of separate regulatory agencies for broadcasting and telecommunications have been well documented. Public policy and regulation must, in future, be formulated for a more integrated information industry; once again, we sense the urgent need for good maps and models to guide the process.

4. MAPS AND MODELS

4.1 Earlier Approaches

Among the best-known attempts at illustrating the information industry and its constituent parts are the "Map of the Information Business" devised by members of the Harvard Program in Information Resources Policy (4) and the "Model of the Integration of the Information Industry" designed by Larry Day for the [American] Information Industry Association and reproduced on the cover of their annual directory (5). These will be described briefly below, together with a model of "The Structure of the Information Industry"

637

produced in a recent OECD report (6) and a pie-chart showing the "Market Size of the Information Industry [in 1986 and 2005]" with the relative share for each sector, published by the Japanese NTT (Nippon Telegraph and Telephone) in 1990 (7).

Although devised for different purposes, the following methods all share one important attribute: they use the singular "information industry" (or "business") to more accurately reflect a growng degree of interdependence as the formerly distinct industries of telecommunications, computing, broadcasting and publishing are being restructured:

The Harvard Map of the Information Business positions various information products and services strategically on the map so that a series of overlays can be used to highlight different aspects of the industry, for instance, its historical development, patterns of government regulation and deregulation, areas of operation of specific firms, diversification of special interests (newspapers), products and services involved in office automation, and so on. The map has proved to be a useful tool for tracking the dynamics of the U.S. information industry.

The Information Industry Association's Model aims to show the continuing integration of the industry sectors. It is divided into eight parts: Content Services, Content Packages, Facilitation Services, Information Technologies, Integrating Technologies, Communications Technologies, Communications Channels and Broadcast Channels. The various products and services are allocated within these divisions, the implication being that the closest integration is to be found between neighboring sections. The Association, founded in 1968 to serve the interests of entrepreneurs in the Content areas, now boasts members in all eight segments.

OECD's Structure of the Information Industry details the three core technologies: computing, communications and broadcasting, the range of hardware needed to support this core, and the types of software and services it generates. It distinguishes between the traditional dominant modes of communication in each of the areas: many-to-one (computing), one-to-one (telecommunications), and one-to-many (broadcasting). The perspective for this model is the *convergence* arising from the digitisation of the three underlying technologies.

The 1990 NTT Pie Charts of Market Size of the Information Industry [in 1986 and 2005] are of interest here because of the four-way sectoral breakdown they use: *telecommunications; information processing; broadcasting;* and a fourth sector that includes "mail, newspapers, *publishing*, etc." The change in the relative share of the pie among sectors from 1986 to 2005 reveals an increase in the information processing share at the expense of both telecommunications and the mail/newspapers/publishing sector.

4.2 An Alternative Approach

Each of the maps and models described above aims to allocate products and services of the information industry among various designated sectors. Mansfield is experimenting with a new approach based on the following premise.

Industry developments are increasingly geared toward providing consumers with more choice among alternative methods of achieving the same results, thus facilitating the substitutability of products and services from various sectors. This being the case, it seems worthwhile to look at the industry from the point of view of *the information functions users will want to perform* and build the model on the basis of an analysis of which sectors can service which functions. This approach may give fresh insights into the true degree of overlap--and consequently of competition--among sectors.

5. THE DEMAND FOR NEW SKILLS

5.1 The Importance of Skills

Whichever models are used to help us to understand the restructuring of the information industry, one thing is certain: the requirements of its various sectors for appropriately skilled professionals and workers will need urgent attention. There are a number of reasons for this:

1) human resources are becoming a new competitive parameter and strategies are being adopted to coordinate the development of both physical *and* human resources;

2) the need for quality and reliability is forcing firms to consider more integrated strategies for managing new technology, work organisation and skills--rigid 'Fordist' or 'Taylorist' standards

are being replaced by more flexible human-centred approaches; and

3) reductions in the availability of unskilled jobs mean that newly created jobs may be more demanding and require multi-skilling (the process--e.g., job rotation, on-the-job training--through which workers are equipped to perform many different tasks within a flexible work organisation).

The Organisation for Economic Cooperation and Development (OECD) has identified three levels at which convergence of different sectors of the information industry can be understood: *technical*, *service*, and *corporate structure* (8). By considering each of these levels in turn, some general trends relating to skills can be identified.

5.2 Skills at the Technical Level

At the technical level, the shift from analogue to digital technology is blurring boundaries, not only between industry sectors but at the level of the technology itself. For example, it is likely that future trends will be characterised by:

- multimedia networks using a hybrid of fibre, copper and wireless;
- multi-service networks carrying a selection of different services (perhaps from different service providers) over the same network;
- multifunctional terminals incorporating a variety of different computational, communicative, and visual functions (9).

The implication is that professionals will need to have knowledge of the major network technologies--namely, fibre, cable, satellite, and mobile communications. At the process level, digitisation of these networks will require skills (e.g., digital programming) that are applicable across the range of networks.

For example, the fact that data and voice traffic are increasingly being carried over the same network is requiring 'integrated' people who are capable of managing this integrated service. While, in the past, individuals may have had a strength in one area or the other, to be effective in future, professionals will need to understand the requirements of both areas of technology (10).

As competition moves to multi-service networks, it will no longer be enough for the professional to know only about technological factors. Increasingly, as we indicated earlier, competitive pressures based on quality of service, pricing, marketing, and demand considerations will require that they be acquainted with these issues in order to effectively participate in teams or projects. In addition, the globalisation of networks and services will require some knowledge of worldwide technical standards and regulation, the legislation governing international information flows, and markets.

5.3 Skills at the Service Level

At this level, the advent of hybrid services (e.g., data broadcasting, narrowcasting and interactive services) is making it difficult to distinguish the various information industry sectors solely on the nature of their service and how it is communicated. As we argued above, there is now considerable overlap between the traditional functions of telecommunications, computing, broadcasting, and publishing; for instance, it is possible for newspapers to be transmitted electronically and data services to be distributed via broadcast channels.

The familiar employment patterns of arts graduates going into broadcasting and engineering graduates into telecommunications may break down with the overlap in services. While knowledge of a disciplinary area will continue to be required, there is likely to be increasing demand for professionals who have cross-disciplinary skills. The blurring of services and the media by which they are conveyed will be largely determined by government regulation. If markets are to be structured in this way, then knowledge of regulatory regimes will be essential also.

5.4 Skills at Corporate Structure Level

At the level of the corporation, telecommunications organisations, computer companies and media conglomerates are restructuring in order to capture markets in a broad range of activities including the provision of networks, interactive services, information delivery, value-added services, and news gathering and dissemination. Mergers, acquisitions and strategic alliances are being formed among information-industry firms all around the globe.

In view of these demands, future managers will have to be conversant not only with investment opportunities but also with cultural factors and regulations at the international level.

Change in corporate structure has implications for human resources, particularly in relation to the categories of staff employed. For example, Koenig has pointed out that the major insurance company, The Travelers, forecast that for the decade 1980-90, the ratio of its professional to non-professional staff would be reversed from 10,000 professionals and 20,000 non-professionals to 20,000 professionals and 10,000 non-professionals (11).

Within organisations, the previously separate information service departments of a company may need redesign to respond to convergence. It may no longer be feasible for the functions of data processing, research and development, telecommunications, and the library to be administered separately. These challenges will require managers who have skills in innovating, as well as company restructuring (12).

5.5 Major Themes

The major themes arising from the above observations are that while specialist knowledge of a disciplinary area will continue to be important, there is increasing pressure for professionals to have some knowledge of related disciplines. Multi-skilling, which is already evident in manufacturing, will continue to be an important feature of human resource development. The progress of digitisation will require more widespread knowledge of this technology. In addition, the ability to manage projects and work in teams is likely to be an increasing requirement in the workplace.

6. RESPONSES TO CHANGING SKILL NEEDS

Industry, educational institutions, labour and governments must develop strategies to cope with the human resource implications of the restructuring of the information industry, particularly that of its largest sector, telecommunications.

6.1 Industry

Industry is perhaps best placed to respond to the demand for new skills. At the highest level, management will need to ensure that human resources are factored appropriately into planning. Strategies which continue to replace labour with capital may have some short-term attraction but could be costly in the long term. Management that is not prepared to embrace multi-skilling practices and human-centred work structures could be limiting its company's ability to move into new markets, especially in a deregulated environment.

The role of information as a resource has to be recognised and managed appropriately. On-the-job training for employees may well need to be supplemented with frequent opportunities for formal education and re-skilling. Company re-organisation may encourage cross-training. For example, employees who have experience in computing may be encouraged to take positions in the telecommunications department; in that way, skills can be broadened. And internal company programs to enable all staff to become familiar with new technologies being introduced in the organisation should be encouraged. A way in which companies can recruit suitable staff is to offer scholarships or work experience to graduates training in a particular discipline. The knowledge gained from formal education can be enhanced by the experience gained from working in a related but different technology or division of the company.

Unless stronger links are fostered between industry and educational institutions, opportunities may be lost. Likewise, failure of management to improve opportunities for multi-skilling at all levels could expose the organisation to increased tensions with labour as job domains and design inevitably change.

6.2 Educational Institutions

Educational institutions have a responsibility to be abreast of the major technological, social and organisational changes affecting the information industry. At one level, degree courses should reflect the integrated nature of restructuring. Students should be exposed to other technological systems which relate to their areas of expertise. For example, a computing graduate would benefit from some knowledge of telecommunications engineering. This interdisciplinary approach is even more important if the skills of teamwork, project leadership, communication, and knowledge of business and political factors are included.

The academic location and design of interdisciplinary courses will be an important factor not only in their success but also in promoting

a fresh approach to education for the information industry.

As the study of the legal, political, economic and managerial aspects of the information industry grows in importance, it may make sense for these subjects to be taught in conjunction with technical subjects. The cross-fertilisation of the social and the technical dimensions would be enhanced if technical faculties were willing to undertake teaching in such areas as strategy and policy formation, once thought to be the sole preserve of arts faculties. This refreshing approach would help to increase the value of course offerings to students, break down disciplinary boundaries no longer relevant to industry, and promote research that is truly interdisciplinary (13).

Upgrading the skills of managerial and professional staff through postgraduate programs is another area where educational institutions can play a valuable role. Appropriately designed courses would allow professionals to gain an understanding of new technologies and their likely trajectories, as well as a broader knowledge of political, economic and regulatory issues affecting the information industry.

Educational institutions must face up to the fact that the latest technology and expertise will often lie outside their campuses. Encouragement and funding for university-industry interchange will be necessary to keep staff knowledge and curricula up-to-date.

6.3 Labour Organisations

Labour organisations, too, will need to be more flexible in their approach to job specifications and skill requirements. While unions have traditionally been strong supporters of staff training, the changes brought about by convergence of information technologies is threatening the very foundations of the unions themselves.

Although the restructuring of the information industry may reduce the number of jobs, the potential for productivity gains could act as an incentive to unions to facilitate and even shape the process of change. With higher productivity, redundancy packages may become more generous, income levels higher, and retraining opportunities more widespread. In this way, the immediate disadvantage of job losses can be counterbalanced by innovative approaches to work design, skills development and training.

6.4 Government

Finally, government has an important role to play in skill enhancement. At a general policy level, government can encourage skills formation by introducing regulations that acknowledge the potential for technological and service integration. This means that regulation will concern itself more with access to, and interconnection of, networks and services rather than relying on specific technological regimes (e.g., satellites, telecommunications, newspapers). Putting artificial boundaries around particular technologies will inevitably lead to market distortions.

More specifically, government will have a continuing role to play in providing a sound educational foundation for future skills development. It should not leave vocational education solely to industry. Government will need to continue to provide a good standard of 'liberal education' as well as the usual opportunities for vocational training. Government encouragement of closer links between industry and educational institutions will be vital.

One mechanism to improve these links would be through the facilitation of short-term exchange between educators and employees in industry. This would promote skills transfer (14). Other possible mechanisms include joint research programs using technology that is shared by industry and the educational institution, and joint sponsoring of courses that are tailored to the needs of particular companies.

6.5 The Quality of the Response

How well the above groups will respond to change will depend on their understanding of the nature and dynamics of the information industry and their willingness to adopt ways that are human-centered, innovative and flexible.

New Directions In Asian Telecommunication: The Soviet Equation

Steve Levy and Deirdre Buell
Pillsbury Madison & Sutro
Washington, D.C., USA

ABSTRACT

The jurisdictional debate over control and oversight of telecommunications activity in the former Soviet Union is at the heart of a basic policy debate within the USSR. Soviet authorities are advocating the evolutionary development of a "Trans-Soviet Line", which on economic and security grounds would constitute a national "backbone" for an integrated, nationwide communication system linking the two extremes of the USSR. This Line would also be used for the purpose of enabling the Soviets to capture hard currency earnings by transiting international calls from West Europe to Asia over their own territory and, of necessity, would link the USSR with contiguous international networks. The initial building blocks for this network are to be installed in various key localities, Moscow, Leningrad and Kieve, where the Soviets have proposed to install international "gateway" switches. At the same time, various republics and municipalities are in the process of exploring other forms of gateway projects which would establish international connections for the republics in their own right and which could also serve "national" purposes by interconnecting European and Asian USSR, albeit via networks transmitting North America. Moreover, republic authorities, or subdivisions thereof, have indicated the desire to establish their own international and regional gateway switches.

There are more issues than answers. For example, the various draft treaties, as well as existing laws, do not indicate the recipient of the revenue from an international system, who receives the interest, nor who controls the traffic. If the Soviet national government uses the facilities of the republics then must the national government pay the republic rent? Will parallel telecommunications systems of the republican governments and the national governments compete? What of the role of purely extreprenurial systems?

The outcome of such debates as well as general issues pertaining to joint venture organization and access to foreign exchange will control the evolution of the largest territorial market in Asia and the most important new laws of telecommunications development.

Various initiatives at the Republic level may contribute to the ultimate answers to such questions. With respect to the controlling legal standards, the Republics are clearly taking charge of their economic destinies. The November 15, 1991 edict relating to "Liberalization of Foreign Economic Activity in the Russian Soviet Federated Socialist Republic" promises sweeping change in the international activity of business entities and ordinary citizens alike. The decree exempts the Russian Republic from central Soviet regulations about foreign economic activity, including import, export, tax, duties and foreign economic activities. Conversely, as a basic element of sovereignty, the edict establishes the primacy of Russian currency. Foreign exchange settlements of local transactions are prohibited. This principal minimizes the hard currency exposure of telecommunications and other joint ventures to local service organizations, thereby conserving foreign exchange for the importation into Russia of western-source goods and services. The decree will also benefit foreign investors in repatriating profits and dividends, but will also limit local companies in terms of their purchase of foreign exchange for imports. This restriction makes sense because, it is fair to assume a chronic deficit of foreign exchange reserves until Russia will be able to balance its foreign trade; hence, limited licensing. Other measures likewise will restrict the access of purely local enterprises to foreign exchange reserves, including a requirement that local enterprises sell part of their foreign exchange receipts an exchange rate that may be different from the freely convertible one.

In sum, the decree sets an eloquent background for free trade and convertibility and a reasonable balance of controls providing for their orderly development.

Introduction

Telecommunications has historically been neglected in the Soviet economy because of a "prejudice against 'nonproductive' activities." (1) In the highly centralized economy, a public telecommunications network was not required for business purposes, and Soviet leaders were wary of citizen access to communications facilities. The telecommunications system was designed to serve official and administrative rather than household needs. The Soviet network evolved as a rigid hierarchical structure which responded poorly to user demands.

President Mikhail Gorvachev initiated reforms of the highly centralized structure, and the administration placed telecommunications at the forefront of development and growth. One million new lines were installed yearly from 1980 to 1985, and two million were added each year from 1986 to 1990. The network was altered to make residential service a priority.

Even before the failed putsch, decentralization of the telecom organizational structure began. Two levels of authority existed - one at the All-Union level and the one at the

Republic level. Traditionally, the two groups did not work well together, and this strain hindered productivity. Gorbachev's perestroika improved this relationship by changing laws and granting Republic Ministries greater independence and responsibility.

In April of 1991, the Deputy Minister of Soviet Communications, Kalijeu Kukk, predicted that the role of the All-Union Ministry, eventually, would be very close to that of the FCC in the United States - a body limited to unifying standards, regulating and licensing throughout the Soviet Union. (2) Prior to the unsuccessful coup, an agreement was signed between the Federal Ministry of Communications and the Republic Ministries of Communications stipulating distribution and sharing of functions and responsibilities. In July of 1991, First Deputy Minister of the Soviet Ministry of Communications, G.G. Kudriavtsev, reflected that the agreement had indeed resulted in heightened coordination of activities carried out among the Republic ministries.

During a session at Telecom '91, Yuri Gulyaev of the Soviet Academy of Sciences, (formerly and perhaps presently Chairman of the Supreme Soviet subcommission on Telecommunications) said that most telecom decisions will be made at the republic level, and the Soviet Union is in need of a central body like the American FCC to administer telecom standards for the various republics. Gulyaev was to propose legislation in the latter part of October 1991 making the activities of the all-Union MPT similar to those of the FCC.

Another aspect of telecommunications touched by perestroika was Gostelradio. President Gorbachev announced in 1990 that he intended to abolish Party control of broadcast operations and ensure the "democratization of the airwaves" by allowing political parties access to the air. Also in 1990, the Soviet Union revealed plans to abolish its censorship organization, Glavit, which for decades was the guardian of the Communist Party line in literature and the arts. Glavit was to be replaced by Guot, an organization concerned with guarding state secrets.

Background

Telecommunications development first appeared in the Soviet Union's 1966-70 Five Year Plan, which called for a Unified Automated System of Telecommunications (EASS). The EASS was to be an integrated network with the capacity to carry voice, video and data traffic. However, little integration took place during the five year period.

The focus upon telecommunications increased in the 1980s. In 1985, the Central Committee and the Congress of the Soviet Communist Party called for a restructuring of the Ministry of Communications. The Prime Minister initiated a program for telecom growth and converted some military communications manufacturing to civilian production. The five-year plan from 1986-1990 sought to add 12.1 million new lines to the system, shift to semi-electronic exchanges, and introduce fiber-optic and digital technology. The plan's emphasis was on residential systems, and 75% of the new installations were to be residential.

The goal of MinSviaz, the Ministry of Communications, was to reach 90-100% urban penetration and 50% rural penetration by the year 2000. Attaining this goal would require the installation of 60 million lines in the 1990s. Yuri Gulyaev outlined the development goals as transition to a digital network, and the deployment of fiber, cellular systems, and satellite communication links.

Former Organizational Structure: All-Union Level

Telecommunications facilities, service and manufacturing operations were state monopolies under the Federal Ministry of Posts and Telecommunications (MPT). Coordinating overall telecom policy, the All-Union MPT was responsible for manufacturing all telecom equipment, developing technical standards, and creating a pricing policy for services of an all-union nature, i.e. long distance and international telephony. New equipment integrated into republican networks had to conform with technical standards provided by a special commission.

An All-Union Ministry of Communications (MinSviaz) operated national and international networks and services, as well as postal services and television and radio broadcasting. The reach of MinSviaz extended to the building, maintenance and operation of facilities for TV and radio broadcasting. The internal organization of Minsviaz consists of a collegium, a scientific-technical council, and a number of Chief Administrations (glavne upravleniia or glavki). The latter included the Chief Administration for Science and Technology (GNTU), the Chief Administration for Industrial Enterprices (GUPP), and the Chief Administration for Satellite and Radiobroadcasting (GKRU).

Prior to its abolition in 1989, the Ministry of Communications Equipment Industry (Minpromsviaz) carried out all production and installation functions. Minpromsviaz was supplied with components and equipment by the Ministry of Electronic Industries (Minelektronprom) and the Ministry Electrotechnical Industry (Minelektrotechprom) which was responsible for component production.

Gostelradio was the State Committee dealing with television and radio broadcasts both in and out of the Soviet Union. It was also referred to as the USSR Ministry of the Radio Industry.

Organizational Structure: Republic Level

Each of the 15 Soviet republics had its own MinSviaz, subordinate to the national MinSviaz and the republic's local Council of Ministers. Fifteen individual MinSviaz administered the facilities in their respective territories.

Each Minsviaz operated on the principle of khozraschet, or internal accountability. Individual enterprises had their own bank account, conducted their own accounting, and were generally financially independent. In 1987, there existed some 7000 financially independent enterprises, 1200 of which lost money in 1987. Minsviaz profits in 1988 totalled 5.3 billion rubles, but 75% was returned to the central government.

The 15 republic networks operated on different standards of equipment with certain networks operating only on a domestic scale. According to law, the Republic governments abided by All-Union standards, and the All-Union ministry was responsible for conducting activities overlapping republic boundaries, but the republican Ministries were fully responsible for the development of the communications networks in their respective republics.

Every Soviet enterprise, large or small, had the right to trade with foreign countries through joint ventures. This right extended to the ministries, both at the All-Union and the republic level. Procurement was handled by the separate republics, but the Ministry of Finance was required to review projects dealing with hard currencies.

Russian Telecommunications Today

In the past, the Russian republic oversaw its own telecom policies, procurement and installation of its telecommunications network within its own boundaries. Russia had its own technical research and development institutes. Today, Russia's control over its telecom system is expanding further as the all-Union governmental structure disintegrates into a body that only exists to coordinate the economic and technological policies of the republics.

In Moscow, local communications are organized by MGTS, which serves 3.8 million local phones through a network of terminal and district PABXs. Inter-district bridges are connected to nine inter-city bridges under Sovtelecom and Moscow through a combination of satellite, microwave and ground cables. Calls are routed within the inter-city network through 12 automatic switches, one for each USSR region.

Special industry networks and/or departmental networks are all connected to the 12 main trunks. Sovtelecom uses 12 main trunks for diverse routing. Trunks exist between the various switches and the Moscow inter-city network. The international switch is Sovtelecom switch number 10 and the Kiev switch operated with AT&T.

Sovtelecom is an All-Union stock company. The Russian Republic holds 72% of the shares, and the remaining 28% is allocated among 25 other long distance companies across the USSR. Seventy percent of Sovtelecom's facilities are in Russia, though the company owns equipment and installations in other republics. Total employment includes 55,000.

When establishing a new project in the Russian Republic, Sovtelecom is subject to a license from the RSFSR Ministry.

An interesting phenomenon in Russia is the specialized networks operated by various ministries other than MinSviaz. For example, the Comincom company has been established to build up and operate separate Digital Overlay Networks in the USSR and has been granted the status of Recognized Private Operating Agency (RPOA) by the International Telecommunications Union. It was formed by the Ministry of Foreign Affairs, Ministry of Communications, the Orbit Bank, and a number of state enterprises.

Its main activities are to provide commercial international telecommunications services to customers and establish and operate international telecommunications centres and local networks to connect customers to them.

The company organizes the export and import of different types of electronic equipment as well as intellectual products. It also provides services in engineering digital telecommunications networks and manufactures different types of communications equipment. The scope of the company activities also spans leasing of local and foreign telecommunications equipment in the USSR and abroad, co-operation, advertising, marketing and training.

Organizational Structure Under the Economic Treaty

In the event that some form of economic union emerges from the shambles of the USSR, some guidance on future collabration on telecoms may be gleaned from the draft Economic Community Treaty. Its usefulness is limited because only eight republics signed the treaty and the principles behind the distribution of authority lack detail, but the balance of power is obviously skewed in favor of the republics. The treaty deems relations between the community and its members to be based upon generally recognized principles and norms of international law. This clause concedes that, indeed, the republics are sovereign nation states.

Any integration of the individual republics is based solely upon the possible economic advantage of coordinating trading, scientific, technological and foreign policies. As the republics switch to a market economy and enter the world economy, members would agree to "bring their economic legislation closer together and conduct coordinated policies in a number of areas." These areas include

scientific and technological programmes of common interest to the community and standardization. It is likely, though not definite, that telecommunications would fall under the realm of such "technological programmes."

The outcome is not merely of theoretical importance. It is at the heart of a basic policy debate within the All-Union structure and the former Soviet republics. All-Union authorities are advocating the evolutionary development of a "Trans-Siberian Line" (formerly the Trans-Soviet Line), which on economic and security grounds would constitute a national "backbone" for an integrated, nationwide communication system linking the two extremes of former Soviet territory. This Line would also enable the Community to capture hard currency earnings by transiting international calls from West Europe to Asia over their own territory and, of necessity, would link the republics with contiguous international networks. The initial building blocks for this network are to be installed in various key localities, Moscow, St. Petersburg and Kiev, where the Soviets have proposed to install international "gateway" switches.

At the same time, various republics and municipalities are in the process of exploring other forms of gateway projects which would establish international connections for the republics in their own right and which could also serve "community" purposes by interconnecting European and Asian USSR, albeit via networks transmitting North America. Moreover, republic authorities, or subdivisions thereof, have indicated the desire to establish their own international and regional gateway switches.

The treaty and the related debate thus raises more issues than it resolves. For example, it does not indicate the recipient of the revenue from an international system, who receives the interest, nor who controls the traffic. If a central agency uses the facilities of the republics then must the "community" government pay the republics rent? Will parallel telecommunications systems of the republican governments and all the all-Union governments compete? The confusion regarding the creation of a Banking Union and the preservation of a single currency adds additional problems. The Community Treaty does not even begin to answer these questions, among others, which will emerge as soon as telecommunications projects are discussed in the national government or in the republics.

On the Cutting Edge: Unilateral Developments Toward Privatization and Currency Reform

Irrespective of what may emerge on a cooperative basis, the various republics, particularly the RSFSR (Russia), have initiated various substantive measures with broad impact on the Republic economy and of particular relevance to telecommunications. These measures include the November 15 edict on foreign exchange and the forthcoming edict on privatization.

With respect to the former, Russia declared itself independent from any external regulation on foreign economic activity and declared its own sovereign mastery over its own foreign economic affairs. As a result, all Russian enterprises are now allowed to engage in foreign economic activities. Such activities were previously subject to strict licensing procedure by the various Central and Republican ministries of foreign economic affairs. Now, licensing of and quotas on import/export operations will be relaxed. Such operations will be taxed, however, at the Republic level.

In order to establish the primacy of Russia currency, on the other hand, foreign exchange settlements of local transactions are prohibited. In the telecommunications sphere, this principal might eliminate the possibility of hard currency settlements by international carriers to local telecos, absent some special, qualifying arrangement for their sharing directly in the foreign exchange revenues generated by international traffic. Such arrangements would be subject to the concomitant principle first mentioned that all enterprises, including local entities, may engage in "foreign" economic activity, including intermediary activity. The status of local telco access and termination of international traffic in this context may require further definition. Obviously, the relevant ministries are obliged to find ways and means to serve the hard currency requirements of local and regional telecos, particularly with respect to the ownership and acquisition of western-source goods and equipment, which are only available on the international market.

The ultimate and long-term solution to such issues is the development of a freely convertible currency. This task is entrusted to the Russian Central Bank. All banks will be authorized to deal in foreign exchange; a market-based foreign exchange convertibility will be allowed; the Central Bank will have a right of intervention; foreign currency accounts may be maintained and used freely by local entities.

An interesting element of the overall policy is that foreign exchange reserves will be developed for the purposes of convertibility through requirements that local enterprises sell to the Russian Central Bank part of their foreign exchange receipts at an exchange rate that may be different from the market rate. Besides tax and duty on imports, this measure will effectively reduce the foreign exchange availability of entities such as local telecos derived from hard currency revenues that they might otherwise earn through settlements on international traffic. At the very least, it will limit the amount of foreign exchange directly under their control and therefore limit their ability to import equipment freely.

On the other hand, local companies will be allowed to purchase foreign exchange for imports, and foreign investors will be allowed to repatriate profits and dividends. Obviously, any joint venture agreement must carefully define the concept of "profits" and "dividends." At the Republic level, such operations, as well as investments by local companies abroad will be subject to licensing. It is fair to assume a chronic deficit of foreign exchange reserves until Russia is able to balance its foreign trade. Hence, there will be limited licensing. The regulations to be developed ultimately may impede the ability of local telecos to proceed to overhaul of their system without a license to import equipment and services. The granting of any such license may be subject to uncertain foreign exchange availability at the Central Bank. The saving grace may be the telecommunications is consistently identified as a priority sector, and therefore may be granted, either formally or informally, special recognition in the context of any licensing regime.

Concerning privatization, the Russian republic has announced that it will issue decrees requiring the ministries to divest their holdings in state companies. It is expected that various state companies will be converted to the joint stock forum, so that shares can be sold or otherwise disposed of on a gradual basis. What is not clear is whether or not such shares will require payment in hard currency, or whether local currency will be acceptable. Consistency with the foreign exchange edict would have the question turn on the nature of the business of the enterprise involved. Obviously, western partners in substantial joint ventures may be under some pressure to "acquire" an interest in their Russian partner through the acquisition of shareholdings. It may yet emerge that the Russian "contribution" to joint ventures may be shares in the constituent enterprise.

A countervailing consideration to western acquisition, would be the position of local management. One of the purposes of privatization would be to turn over operations to a cadre of local managers conversant in the dynamics of the state enterprise. Obviously, such "management buy-outs" would be a principal way of perpetuating incumbent interests.

In the absence of overall direction, local authorities have conducted privatization on an ad hoc basis. In all such cases, however, there is the general problem of evaluating Soviet assets. In addition, some of the largest pending such privatization efforts--principally in the automobile industry--have been hampered by disorganization at the government level. It is not always clear to potential acquirers to whom they should be talking and who even owns the assets in question.

BUSINESS TELEVISION IN THE PACIFIC RIM

Dr. Kathleen J. Hansell
KJH Communications, Atlanta, U.S.A.

This paper presents a brief summary of preliminary findings about satellite networks used for private video broadcasting. Such networks are particularly prevalent in the U.S. and in Japan.

INTRODUCTION

This paper is a summary of some of the preliminary findings from the study *Worldwide Business Television Networks*, undertaken by KJH Communications in late 1990. This multi-client study surveyed private, program, and educational satellite networks around the world. (Networks that have as their major purposes the provision of entertainment and those that serve sports operations were excluded from this study.) Data for private networks that operate in North America and Asia, and specifically in the U.S. and Japan, are summarized in this paper. Private networks are defined as those that are operated by companies, government agencies, or non-profit institutions for purposes of providing information, training, and motivation to employees, franchisees, resellers, and/or customers.

GROWTH IN NUMBERS OF NETWORKS

Our study examined over 250 networks worldwide and found that 127 networks met our criteria for private networks, which included a requirement for having broadcast during 1990 at least six programs to permanently installed downlink sites.

The greatest number of networks (see Figure 1) is found in North America, where the practice of using Ku-band satellite frequencies for private networks first became popular in the early 1980s and where there has been an annual increase in operating networks to the 1990 total of 68 networks. All but one of these North American networks operate from the United States. The second largest number of networks is found in Asia, where all but two of the 45 Asian networks operate in Japan.

A look at the numbers of operating networks year by year shows interesting growth patterns (Figure 2). Observers of the market in the United States were extremely optimistic in the mid and late 1980s about the continued adoption of business television networks, and indeed the growth patterns were strong through 1989. The picture began to change in 1990, however. For a variety of reasons, including the slowdown of the U.S. economy, fewer new networks were established and several existing networks ceased operation, resulting in a decrease in the growth rate. The resulting growth curve resembles not the "hockey stick" effect predicted in 1988 but the beginnings of a more classical "S" curve of innovation adoption.

The rapid deployment of networks in Japan since the launch of JC-Sat in 1989 shows a sustained rate of growth in numbers of networks through the end of 1990, even in the face of the failures of the two Superbird satellites. The question for forecasters is whether this rate of growth in operational networks will be sustained, given the beginning of a slowdown in the Japanese economy and the possibility that some existing networks, having tried business television, may decide against continuing.

DOWNLINK SITES

The 127 business television networks worldwide account for over 40,000 downlinks (Figure 3), including TVROs that are designed solely to receive video programming and VSAT downlinks that transmit and/or receive data as well as receive video programming.

The 30,000 downlinks associated with the North American networks and the 12,000 downlinks in Asia yield average network sizes of approximately 270 and 440 sites for North America and Asia, respectively. The larger average size of the North American networks reflects the presence of several VSAT data/video networks with several thousands of sites in the United States, primarily in the automobile manufacturing and retail industry segments. In Asia, the business television average network size is not yet influenced by large VSAT data/video networks.

INDUSTRY SEGMENTS

Worldwide private networks represent a number of industry groups (Figure 4). Manufacturing companies account for the greatest number of networks in both North America and in Asia. The largest numbers of networks are found in the office equipment and electronics industries, where networks are used for disseminating product information to internal and external

audiences, including customers, and for training employees of the manufacturers and their dealers. In the automotive industry, networks provide a variety of information to employees of manufacturers and their dealers.

Financial services companies account for the second largest number of networks in both North America and in Asia. In this industry group, insurance companies and non-bank financial services providers (securities and investment firms) are most represented. With one exception, banks are not users of business television networks, primarily because of the political boundaries within which they operate.

With few major exceptions, industry groups represented by private business television networks in the United States and Japan are essentially the same. One exception is the presence of business television in the construction industry in Japan.

TRANSPONDER USAGE

The method for procuring satellite time and the annual usage varies greatly, depending on the applications for the network (see discussion below). The majority of users book transponder time on an occasional basis; however, those with regular program schedules or extensive programming rely on part-time or full-period transponder leases. A sampling of approximately 30 percent of the Japanese networks yields an average annual usage of approximately 300 hours for 1991; usage on the U.S. networks, based on a 90 percent sampling rate, is approximately 470 hours.

Coverage is almost always domestic only. There is little use of international satellites to distribute business television programming between Asia and North America, primarily because of the vast differences in time zones and the additional cost to reach relatively smaller audiences.

APPLICATIONS AND BENEFITS

Most applications of private business television networks can generally be classified as corporate communications, product information, and skills training. In addition to these major categories, there are many unique applications for satellite-delivered private network programming.

Corporate Communications

In Japan, company chairmen use their networks for new year's greetings. Other annual corporate communications programs include year-end financial and business summaries and statements of directions for the new year. Similar programs, including sales "kick-off" meetings, where sales targets and strategies are revealed, are common annual events in the United States. And the death of a founder or senior officer in either country is usually covered on the network.

Corporate news programs are common in the United States and Japan. These programs range from 5-minute daily news programs based on the previous day's business and financial events to longer magazine-format programs that include segments designed more for motivation and fostering company spirit than to satisfy need-to-know requirements. While many networks begin by using professional anchors to host these programs, many find that employees of the corporate communications department, though not as polished in performing on the air, contribute more credibility to the broadcast.

Companies in both countries use their networks for a variety of management communications. Where scrambling equipment is employed, regional messages can be targeted to appropriate downlink locations.

The chief advantage of satellite networks over other delivery vehicles for corporate communications is the ability to inform large numbers of people simultaneously. In order for communications to be perceived as credible and significant, networks must apply certain journalistic standards to programming that is featured as news or commentary, and networks must guard against trivial and overly long productions in all programs.

Product Information

The dissemination of product information occupies the largest amount of broadcasting time on the private networks. Programs deliver marketing information to internal sales staff or dealer personnel as well as technical information to technical support personnel, service technicians, and customers. In some instances, broadcasts are aired without scrambling in order to provide video information that can be used on public or commercial television stations.

The chief advantage of satellite networks for disseminating product information is the ability to shorten the cycle time for informing a field force. When a new product or product feature becomes available, information can be communicated directly to the individual in the field without the need to send it through layers of management in the field organization. This time advantage may cause concerns among middle management personnel in traditional bureaucracies, who may perceive the network as diminishing their responsibilities and stature in the organization.

A major challenge for almost all networks is the control of program content. Product managers, who are often the "clients" for product information types of programming, often need help in translating face-to-face

presentations into formats suitable for the television medium. Targeting specific audiences, choosing a limited amount of critical information to be conveyed, and generally limiting the length of these programs are the biggest challenges to network managers.

Skills Training

In this study, we use a strict definition of skills training to mean instructional programs where objectives are clearly defined and there is some change in behavior desired from the viewer. We differentiate this type of programming from the mere dissemination of information. Many companies do provide their audiences with well-designed training delivered over their networks. Interaction during the training program may be carried via telephone, facsimile, a still or motion return video link, or data response units that employ a keypad for polling, testing, and otherwise obtaining feedback from participants.

The chief benefits to using business television networks for training are cost savings from less travel, the ability to train more people using the same training resources, and the reduced amount of time that salespeople spend away from their customers and their sales territories. The greatest challenges for companies using satellite networks for training are in developing courses that are sufficiently rich in activities and information so that the audience can develop skills in a comfortable training environment. Well-run training programs often combine local activities with satellite-delivered activities and make use of a mix of delivery vehicles including instructional hardware and local facilitators at each site.

SUMMARY

This brief paper presents only a small portion of the study data, but enough to see that satellite networks have been embraced by a number of companies in North America and Asia, and particularly in the U.S. and Japan, with various requirements for communicating to dispersed employees, dealers, customers, and other audiences.

"The Evolution of Voice Processing -- Integration of Voice and Data as a Strategic Advantage for Pacific Rim Companies Operating in a Global Market."

By Mr. Jan Waluk
General Manager for Asia Pacific and Latin America
Octel Communications
Milpitas, Calif., U.S.A.

The Pacific Rim is emerging as a major market in the global economy. At this critical point, when a region is one of the fastest growing in the world, it is crucial that information access be timely and accurate. With the recent trend in the telecommunications industry where two technologies, voice and data, have been integrated, voice processing has become an effective way to communicate at any time and from any place in the world.

The sun is rising on a new industry, voice information processing. This paper will address economic and technology trends that have paved the way for sophisticated transnational communications. On a more direct level, it will explore the emergence of voice information processing; the benefits of the technology; its growing presence in the Pacific Rim; and finally, how it translates to maximum productivity and reduced costs for companies operating on a global scale.

Voice information processing, the marriage of voice and data processing technologies, is allowing multinational companies in the Pacific Rim (Pac Rim) to conduct business with a global handshake. It is estimated that trade between North America and other Pacific Rim countries was worth $US15 billion in 1970, growing to $US215 billion today, and could rise to $US750 billion by the end of the decade (1). With this unprecedented trade activity, communication technology has met its challenge.

"Globalization" has been more than a trend and a fascination, it is the hallmark of the twentieth century, and nothing has accelerated the momentum of globalization quite like the telephone, which has been dubbed the ubiquitous terminal. If information is a company's most strategic asset, then the ability to mobilize it efficiently and expediently through voice and data technology will be a company's highest strategic advantage.

Voice information processing technology -- the means to link voice-, text- and image-based information over international telephone networks -- is becoming the preferred global business connection. Not only does it provide a seamless interface among computer databases, fax machines and voice mail boxes, but it also bridges the time and distance gap. Users can access time-sensitive information or deliver important messages at any time from anywhere in the world, in a single telephone call.

Growth in the Pacific Rim

A confluence of trends are contributing to the explosive growth in the Pacific Rim. The export-driven growth of the 1980s has created a higher standard of living and there is a surge in the demand for consumer goods: TVs in Malaysia, cars in Indonesia, telephones all over the region. At the same time, the labor costs and manufacturing sophistication in the region have created a new land of opportunity and high profits that the whole world would like to tap.

As a spokesman from Texas Instruments (one of the largest corporate investors in Asia) pointed out, "If you're going to be a player in the '90s, you've got to be in Asia" (2).

As the Pac Rim grows into its position as the number two supplier of products worldwide, supplanting Europe, global highways carrying vital information on technology, vendors, suppliers, customers and market conditions, need to accommodate the intensified information traffic.

Pac Rim Tigers

The four "tigers" or "dragons," Hong Kong, Singapore, Taiwan, and South Korea, have shown exceptional manufacturing strength with active capital and financial markets.

Hong Kong, for example, a long-time free-enterprise and free-trade economy has earned its international reputation as a leading manufacturing and commercial center. Because of its favorable economic climate, productive work force and strategic position in the Pacific Rim, Hong Kong has garnered foreign capital, mainly from the U.S., Japan and the United Kingdom. Hong Kong will continue to be a vital center of communications for the Pac Rim community.

Japan warrants little introduction to the Pacific Rim forum. With a gross national product pushing 400 trillion yen with total exports nearing $US300 billion (3), Japan is a vital force, worldwide, not only in the Pac Rim.

Developing and developed countries alike, realize that an advanced communications infrastructure is a prerequisite for attracting new business investment. Thailand and Malaysia, witnessing the success of the four dragons, are adopting technology that will invigorate their economies. Thailand envisions the addition of 3 million new telephone lines, while Malaysia's current telephone density of 8 percent is expected to climb to 25 percent by the end of the '90s.

Australia, whose exports have grown manifold, has become a popular world trade partner. To support the surge in world trade, Australia is developing a regional telephone network that will expand from its current 37 million telephone lines to some 325 million over the next 50 years (4).

633

Expanding Transnational Communications

To sustain the increasing economic activity in the Pacific Rim, the availability of advanced communications technology will need to expand at an even faster rate than investment and exports. And there is an aggressive response from telecommunications companies on the other side of the Pacific (the U.S.) to capitalize on the emerging Pacific Rim telecommunications market.

Just as barriers are breaking down to create a contiguous global marketplace, barriers to competition in telecommunications are also falling. Deregulation and privatization of national telecommunications companies especially in the Pac Rim, are creating an intense competitive climate. New telecommunications companies moving in from abroad are pressured to provide global solutions to their corporate customers who have gone "global." As a result, a vast intercontinental infrastructure for both fixed and mobile transmission is in the making, and partnerships are being formed to lay transoceanic voice and data cable systems.

A recently announced Asian fiber optic cable will be owned by some 38 carriers to link Singapore with Japan, via Malaysia, Hong Kong and Taiwan. California is also a major economic power in the Pacific Rim (some say the sixth strongest in the world), and technology to increase transmission speed among California, Australia, New Zealand and Japan will soon be in place.

At the Pacific Rim Futures Conference (September 1991), an officer said, "It cannot be overemphasized: telecommunications and technological changes have caused and will continue to cause more globalization, greater interdependence, instantaneous informational flows, immediate recognition of financial risks and opportunities..."

As an indicator of heightened business activity between countries, international corporate voice, data and teleconferencing (measured in messages per minute) is growing at an annual rate of 15 percent to 20 percent, nearly double the 7 percent to 9 percent corporate domestic rate, according to Arthur D. Little (Cambridge, MA).

A sampling of the 10 top countries the U.S. talks with the most includes three Pac Rim countries: Japan, South Korea, and the Philippines. Telephone calls in millions of minutes from the U.S. in 1990 were 214, 164 and 163, respectively (5). With the proliferation of voice information processing and the ability to access multiple information sources across nations and continents, the frequency is sure to be on the rise; meanwhile, the demographic representation may change as the Pacific Rim captures more of the top 10 spots.

Voice Information Processing for Cellular Users

In addition, the cellular industry is moving toward offering a more comprehensive suite of integrated voice, data and image applications. In 1990, the Asia/Pacific Rim countries accounted for 15 percent of the world's cellular subscriber base, or 1.6 million. Within the region, Japan will be driving the growth accounting for nearly half the customer base by 1995 (according to EMCI Inc.). In the streets of Tokyo, for example, it is not uncommon to see mobile phones in the hands of ambitious people, who can't afford to miss a beat -- whether it's stock prices on the Tokyo Stock Exchange or a promising sales lead.

Cellular providers have been quick to answer customer needs and to seize new marketing avenues with enhanced information services. Meanwhile, those who are serious about closing the communications gap through cellular phones are just as serious about the services voice information processing can provide. For example, mobile callers can retrieve messages from voice mail, instantly access audiotex services for updates on key corporate or financial news, and leave a detailed message with a business associate that needs to respond immediately to the news.

Where timely information means the difference between success or failure, mobile communications coupled with voice information processing allows users to hedge the risk of missing important news.

Voice Information Processing: Emerging Technologies

Traditional voice mail involved little more than the use of computers to electronically store voice messages for later retrieval. In time, more advanced voice mail capabilities, such as automated call routing and distribution, voice-prompted forms registration and voice bulletin boards, emerged. Today's voice information processing offerings include a range of voice, data and image technologies that can be integrated into one phone session; they include:

Interactive Voice Response -- The ability to input and retrieve information from a computer database via touch-tone telephone. Provided that 80 percent of all U.S. telephones and a growing percentage of international telephones feature touch-tone dialing, banks, universities, and newspapers, to name a few, are automating customer service with voice information processing. The benefits are improved responsiveness and a better allocation of resources.

Fax Publishing (Fax-On-Demand) -- The ability to request that fax information be automatically forwarded to the caller via touch-tone phone. With fax publishing, companies can disseminate current information -- from price lists and product brochures to contracts and healthcare benefits -- to their customers, clients, contractors and employees. In this way, postage costs and long distance telephone costs can be reduced, while information can be expediently delivered.

Audiotex Access -- The ability to access timely news residing on computers via satellite feeds to the telephone. Many companies are generating new revenue by offering audiotex services -- from newspapers which offer audiotex-based news updates to financial companies which provide up-to-the-minute access to breaking news and stock market reports.

Two-Way Message Notification -- The ability to link voice mail and electronic mail systems so that users can collect all messages -- voice- and text-based -- through a single source. This capability encourages better communication and decreases the time and costs associated with accessing different, incompatible systems.

Voice Recognition Response -- The ability for people to interact with computers by speaking commands into their telephones. This development is a natural interface for applications such as order placing and sales reporting. In the not so distant future, voice recognition technology will be able to read computer-based E-mail messages to users who call in from remote sites.

Applications Mix

Designed for customization, voice information processing allows customers to pick and choose from a variety of different applications. Given the flexibility of modular systems, management can choose the appropriate mix of voice and data modules to fit current needs and expand applications and systems as the company expands.

Evolution of Integrated Solutions

Over the past two years, E-mail, voice mail, fax, cellular phones, audiotex and interactive voice response have improved information access and responsiveness. Until recently, these technologies did not provide complete solutions because they were stand-alone, not integrated solutions. For example, when faced with stand-alone solutions, an employee traveling overseas -- who wants to connect with the home office -- calls one number to retrieve messages from voice mail, then logs-on to a computer to inquire about electronic messages, and then calls a third number to inquire about faxes. Today's integrated solutions offer the same traveling employee convenient access to messages, E-mail and fax in a single phone call. The advantages of integrated solutions become more significant when companies are calling overseas, because time saved translates to even greater savings in long distance rates.

The Benefits of Voice Information Processing

In the age of lean corporations and fierce competition, voice information processing technology can help companies reduce labor costs by automating tedious telephone answering and basic message response. It can free-up staff for more important and productive tasks. It can increase accuracy and efficiency by eliminating message errors and by automatically forwarding messages to groups of people for more immediate action. It can augment security by enabling fax and/or messages to be sent to private mail boxes rather than a public fax. It can provide access to more information sources via computer databases and satellite services, and the list continues.

With respect to labor savings, studies suggest that the use of voice messaging alone will save a company on average, a half an hour per person per day (6). Voice messaging lessens the chance that a message will be lost or misinterpreted, and it eliminates frustrating telephone tag!

Enhancing A New Management Style

Fundamentally, this new technology can boost employee involvement and awareness through open communications at all levels -- peers, superiors and subordinates -- leading to higher worker output and satisfaction. This decentralized corporate communication characteristic of the Japanese style of management, has been successfully imitated by the U.S. and others. Though hierarchical, it is also participative, and western business cultures have begun to notice the positive repercussions on the way people interact, create, and execute tasks, not to mention improvements to productivity and a company's bottom line.

Because voice information processing brings together people from different levels and locations with decision-critical information, it will play a key role in optimizing the benefits of the decentralized management structure. For example, a project leader can easily send out a single, standard message to a programmed set of individuals, relaying project completion dates, special policies, or even feedback. This serves to reinforce project completion and proves a necessity when the project team is divided between the Pacific Rim and the U.S.

For instance, sales people can pass on customer requests for new products/services to management. At the same time, these messages can be simultaneously passed on to customer support and product development at corporate headquarters in another city, state or country. By involving management, product development, customer support and sales at the onset, better solutions are apt to be found more quickly.

Acceptance of Voice Information Processing

Implied in the technological impact of voice and data technology is the sociological impact, which may greatly reshape the way organizations function and the extent to which people use the telephone to their utmost advantage. The acceptance level of voice processing is high, and the same is expected for voice information processing. The reasons are simple: for most of us, the phone is a natural extension of the way we communicate, and the operation of its keypad couldn't be made easier; it has been around for most of the 20th century; and it has played a major role in our personal and professional development.

In contrast to the personal computer that becomes intuitive once commands are learned, voice information processing provides a voice-based instructional interface that guides a user by providing options. With voice information processing, commands need not be learned, and users can discover a number of innovative ways to communicate across distances.

The Markets Served

Among the major markets for voice information processing are banking and finance in such applications as account inquiry and transactions; insurance for coverage verification and premium quotes; transportation for scheduling and shipment tracing; manufacturing for inventory and product cycle communication; and the service industry for mail order and credit card requests.

Other markets include healthcare to streamline communication among medical professionals; colleges and universities for registration, campus events publicity and ticket orders, career information, and increased professor/student communications; state and local governments for increased responsiveness to public concerns and coordination among the different government agencies; and publishing for classified advertising, opinion polls and information bulletins.

What a Difference a Day Makes...

In the context of international business and communications, 24-hour access to information is imperative because a business associate in one part of the

world may be leaving work when others are starting their workday. Although voice information processing technology can't eliminate time zones, it allows business counterparts to carry on projects that might otherwise have to wait 12 even 16 hours depending on geographic locations.

The fax machine has done much to bridge the information flow given time changes and multinational operations. Voice information processing will take international businesses another step in providing continuity between groups working in tandem from different parts of the globe. The productivity leaps are already impressive, and the technology is still in its early stage.

Case Histories

As an example of bridging time-zones through voice information processing, McDonald's, which has become an international icon, has set up a network of Octel voice mail boxes to foster communications among offices in the U.S. and Australia.

With the communications hub in Chicago, offices in Sydney Australia (12 hours ahead) can program their messages so to be sent at 10:00 p.m. Australia time for early morning pick-up by their U.S. counterparts. In this manner, there is a more continuous information flow, and McDonald's can save money by transmitting messages during off-peak times.

With a carefully constructed database, general information pertaining to McDonald's facilities, construction, equipment and marketing, can be immediately channeled to various destinations as far down under as Sydney and Melbourne. Senior executives at McDonald's also use the systems to broadcast new environmental policies or send press releases to the regional managers -- a form of internal public relations.

Beyond bridging time-zones, Celcom Malaysia is an example of targeting technology to cultures and languages. Celcom Malaysia, operator of Malaysia's latest mobile communications network, ART 900, installed Octel's voice messaging and interactive voice response applications to meet the rising demands for more extensive mobile or remote communications services in that country and around the Pacific Rim.

Celcom Malaysia will offer multi-lingual prompts in Malay, Cantonese and Mandarin in addition to English to guide users through the applications. The first installation of its kind, Celcom Malaysia will initially focus on integrating Hong Kong and Taiwan into the network and subsequently expand communications into other countries in the Pacific Rim.

Publishing is a strong market for voice information processing because it is by nature a gatherer and purveyor of information. Telephone answering, voice messaging, voice bulletins and audiotex information allow publishing businesses to save money and free-up people for more interesting tasks, while providing a higher level of service to their readership and advertisers.

Singapore Press Holdings, which has the largest daily newspaper in Singapore, found that adding voice information processing was a move "to stay on the forefront," as the publishing industry changes. For Singapore Press Holdings, this technology is more than a round-the-clock advertising tool, it is an up-to-the-minute information provider as well. Classified advertisers can have inquiries left in a personal mail box so they aren't disturbed at home. Users can call in for weather bulletins, tide and flood information. There are also lines for sports and financial news. Editors can also poll their respective communities on political events and controversial issues.

Because of the multitude of tasks that can now be performed with voice information processing, and its impact on productivity as we operate more on an international scale, this technology may eventually be thought of much as the telephone itself: one can't imagine existing without it.

AN UPDATE OF OFF-THE-BEATEN-TRACK DIGITAL NETWORKS;

A CASE STUDY FROM INDONESIA

Christopher Bent Sivertz, P.Eng
Nigel Bailey
Infosat Telecommunications Ltd.
Vancouver, Canada

During the first two years of this decade, the International Satellite Telecommunications regulatory environments experienced dramatic changes. With advances in earth station technology imminent, these changes will rapidly lead to the redefinition of International Networks.

This paper illustrates this redefinition through a case-study of a Texas-based multinational corporation. Their Indonesian operation consists of a regional office in Jakarta which supports several isolated exploration and production sites.

The Texas-based organization's objective, shared by its numerous counterparts, is to effect reliable communications with its international operations.

INTRODUCTION

Multinational Resource Development Corporations (RDC's) are second only to the U.S. Military in their pioneering efforts to push the latest Telecommunications technologies to the extreme limits of their performance.

An example of their early influence is the widespread use of HF Radio transmission to provide interconnected - telephone and telex communications to remote regions. Because RDCs had both a need for this capability, and the budget to pay for it, they enabled the Telecommunications Industry to develop and commercialize HF Radio Technology. Now commercial automated HF Radiotelephone service is available to fixed, mobile, and marine users, worldwide.

RDCs also pioneered the early development of automated VHF Radio-telephone technologies. Out of necessity they implemented this service wherever possible, and extended it into remote areas of North America during the early '70's.

This early development made North American communications firms world leaders in radio network technology. Corporations such as Motorola developed a wide range of sophisticated radio network advances, including Trunked-Radio, Paging, and Cellular Telephone.

RDCs were also among the first to adopt Inmarsat's L-Band Global Satellite telephone service and, as high volume users, helped to drive its commercialization to its practical extremes.

It is no surprise, then, that the recent global expansion of North American private voice/data networks again finds RDCs in the forefront. Their missionary-style role continues in their use of domestic satellites for private network services in developing nations.

In Indonesia, Mobile Oil pioneered the use of the Palapa Satellite System for private network service in 1988. Shortly afterwards, in Ecuador, Unocal followed suit, using PAN-AM SAT. What had previously been thought unviable due to technical and regulatory factors, the use of domestic satellites for private network services has evolved rapidly in developing nations, fuelled by the involvement of RDCs!

As they influenced Radiotelephone commercialization, RDCs have helped pave the way for other industry sectors in these developing nations to expand their voice/data networks. Less than four years after Mobile Oil's benchmark, several dozen private networks have been installed in Southeast Asia and Latin America. Using Palapa, PAN-AM SAT, and Asiasat, industry sectors in Transportation, Finance, Hospitality, Retail Distribution, and other areas, now operate private domestic satellite networks.

Lacking terrestrial alternatives, they have adopted domestic satellite as the most cost-effective means of providing reliable communication between operations dispersed within a developing

nation. In only a few days, any remote operation's contact with the regional office is transformed from sporadic speech over HF Radio, to fully integrated telephone/facsimile/data service using digital transmission, via domestic satellite.

In fact some of these private networks are providing remote operations with a grade of service equal to, or superior than, that available to their North American counterparts! This sudden abundance of information has allowed the management of these remote regions to make use of greater external input to aid in their decision making.

Unfortunately the implementation of state-of-the-art digital communications between domestic operations in a developing nation has limited benefits without complimentary access to international services. Regulatory and technical barriers limit the implementation of private international satellite networks, and overcoming this obstacle has become the latest challenge to global expansion.

Again it is the RDC's, with their long history as users of private domestic networks, who are pioneering access to international services.

The RDC that will likely be the first to succeed in overcoming these obstacles in its attempt to extend its international network to include Houston, Jakarta, and beyond - is the subject of the case study which follows.

CASE STUDY

OVERVIEW

This study describes the experiences of a Houston based multinational corporation with decades of experience in petroleum exploration in remote locations, worldwide. It currently has a regional office in Jakarta, with several remote operations throughout Indonesia.

Over the past 3 years this RDC has been installing a private domestic satellite network to provide communication between the Jakarta Office and Remote Sites. Digital transmission enables simultaneous voice, data, and facsimile service over this network.

Communication between the Jakarta and Houston Offices, however, depends on the local and international PSTN's (Public Switched Telephone Network). Analog transmission permits substandard voice, inconsistent facsimile, and unreliable data service.

OPERATIONAL OBJECTIVES

Houston-Jakarta Communications:

Over the past five years, this RDC's management has gravitated towards the Houston-based Corporate Information Services Network (CISN) (see Sheet Six) as a primary communications media. With the CISN's capabilities growing steadily and now able to support Voice-Mail, E-Mail, LANs, etc, the importance of having regional offices "on-line" is also increasing.

For the Jakarta operation, this means reliable voice, data, and facsimile communications with Houston, as shown in Sheet One.
Ultimately, the Jakarta Office will act as an international node on the RDC's private network. As shown in Sheet 8, this requires that the following communication interface with Houston:

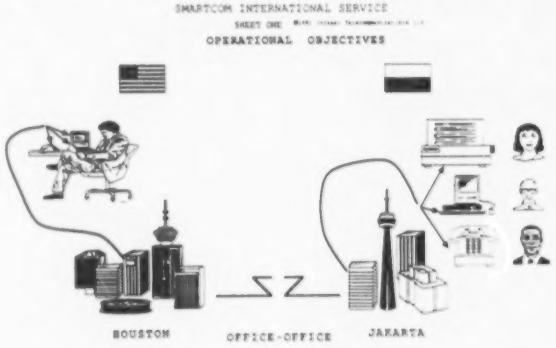
-support of a small Local Area Network
-local PSTN interconnection
-Group III facsimile service
-direct-dial voice service
-local PSTN modem access

Houston/Jakarta-Remote Site Communications:

Confronted with rising remote site daily operating costs, lower production yields, and fluctuating market prices, RDCs must manage international exploration and production activities more efficiently.

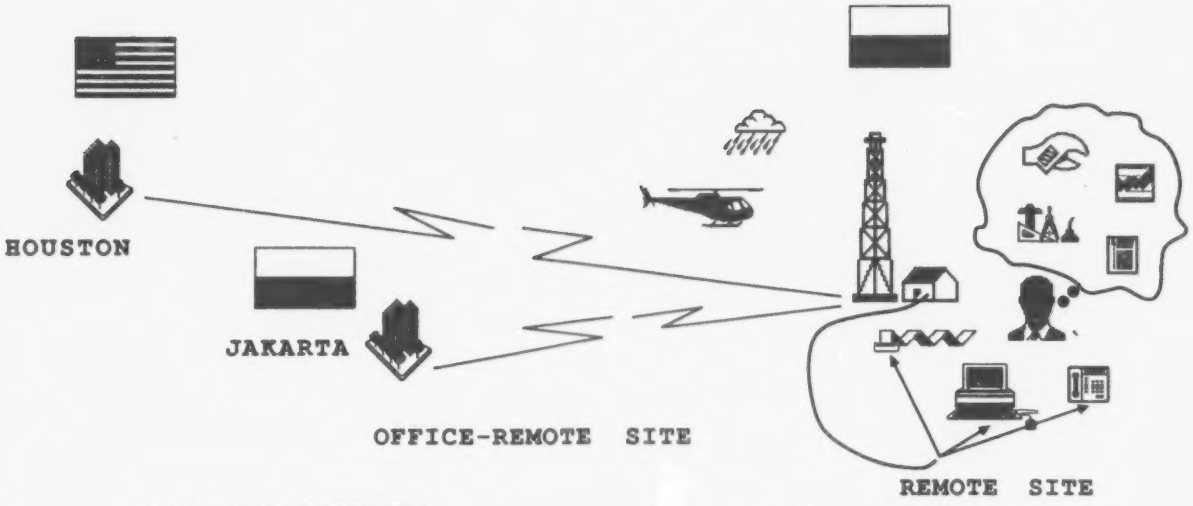
In this case, major efficiency improvements in remote site operations are identified through access to both the Jakarta Office and Houston's CISN. (See Sheet Two)

Reliable voice, facsimile, and data communications will facilitate Houston's technical and operational support on an as-needed basis, reducing remote site downtime. (See Sheet Nine)



SHEET TWO ©1991 Infosat Telecommunications Ltd.

OPERATIONAL OBJECTIVES



LOGISTICAL CHALLENGES

Houston-Jakarta Communications:

A wide range of Houston-Jakarta communication services, readily available from Submarine Cable and International Satellite, cannot be implemented due to the "Last Mile Problem". (see Sheet Three)

The ownership, operation, and maintenance of Indonesia's (not unlike USA's) wired telecommunications network resides solely with the state-owned PTT.

Saddled with the same dilemma that is faced by many other developing nations, that of trying to meet an enormous demand for POTS (Plain Old Telephone Service), the mandate of Indonesia's PTT focuses on basic subscriber services.

In Jakarta alone, the next decade will see the installation of 1,000,000+ basic subscriber lines. This will result in a ten-fold increase in the number of telephones per person. Nearing 1 line for 20 people by the year 2000, Jakarta's penetration will still fall far short of North America's present 1 for 2 level of service.

With Indonesia's PTT committed to at least one decade of continuous expansion and transition, cabled connection to international gateways will remain a significant challenge to reliable network services.

Houston/Jakarta-Remote Site Communications:

Jakarta-Remote communication has relied mainly on HF Radio due to (a) the lack of existing telephone service in many regions, and
(b) the large geographic area managed by the Jakarta Office. HF Radio, at best, is useful for restricted "push-to-talk" voice communication, but remote access to network services such as Telephone Voice, Facs, and E-Mail has proven to be impractical using this technology.

The recent advent of private domestic satellite networks has given remote sites direct access to the Jakarta Office's communication services. However, when the telephone traffic in and out of each remote station is switched through the Jakarta Office, the result in a significant increase in demand for (and decrease in availability of) local (Jakarta) PSTN lines. Having only 3 voice (+1 Facs) lines, (often reduced to 2 or 1 due to service outages) the Jakarta Office Telephone Switch is overloaded with local calls from 8am to 10pm (6pm-8am Houston time).

This means that for 14 hours out of every day, Houston-Remote communication is not available. The lack of reliable facs or data (due to Jakarta's PSTN) makes voice the prime means of communication between these points. So late-night telephone sessions with Houston are held, but only during critical circumstances.

OPERATIONAL OVERVIEW

Houston-Jakarta Communication:

In order to resolve the Jakarta Office's communications bottle-neck, the RDC asked for permission from Indonesia's International Signatory to operate a dedicated Jakarta-Houston satellite circuit. Ultimately seeking the on-site installation of the Jakarta Office's private international satellite station, the RDC knowingly faces an administrative process that will take some time to complete.

This digital international satellite circuit, operating at 64 Kbps, gives the Jakarta Office direct access to the Houston Office. (see Sheet Five)

Equipped with PCSI Voice/Data Multiplexers, the HOU-JKT circuit can be configured to carry 0 to 8 voice channels and/or 0 to 8 data channels operating up to 64 Kbps. (see Sheet Six for Houston's requirements)

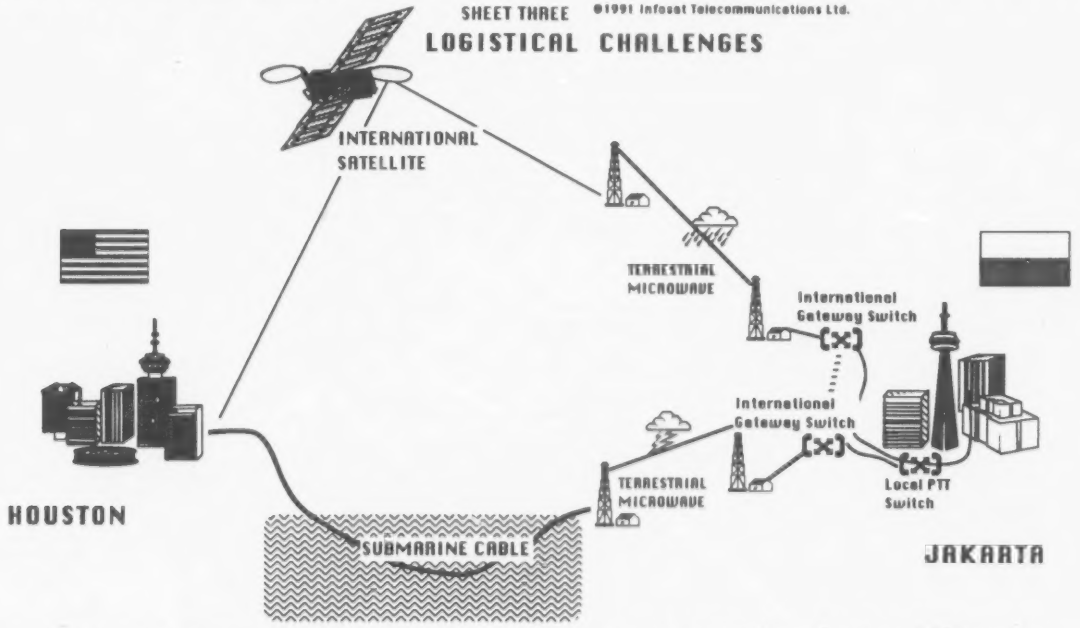
The PCSI units are configured automatically according to a pre-programmed schedule that reflects international traffic patterns. A typical program entails re-allocation of circuit capacity on a daily routine as follows:

Sample PCSI Programming
64 Kbps (HOU-JKT)

Slot #:	Jakarta Time:	Circuit Configuration:
1	6am-1pm	28.8 Kbps data for LAN connection 38.4 Kbps for voice: 2@15KBps for Houston-Remote (2-Hop) 1@8.4KBps for Houston-JKT
2	1pm-9pm	56 Kbps data for LAN, etc 1@8KBps voice for voice-mail, etc
3	9pm-1am	9.6 Kbps data for LAN, etc 3@15KBps voice for Houston-Remote (2-Hop) 1@9.4KBps voice for Houston-JKT
4	1am-6am	56 KBps data for LAN, etc 1@8KBps voice for voice-mail, etc

SHEET THREE ©1991 Infosat Telecommunications Ltd.

LOGISTICAL CHALLENGES



In this example, the two PCSI units connected to the 64KBps HOU-JKT circuit are programmed for four time slots.

SLOT #1; PROGRAM RATIONALE

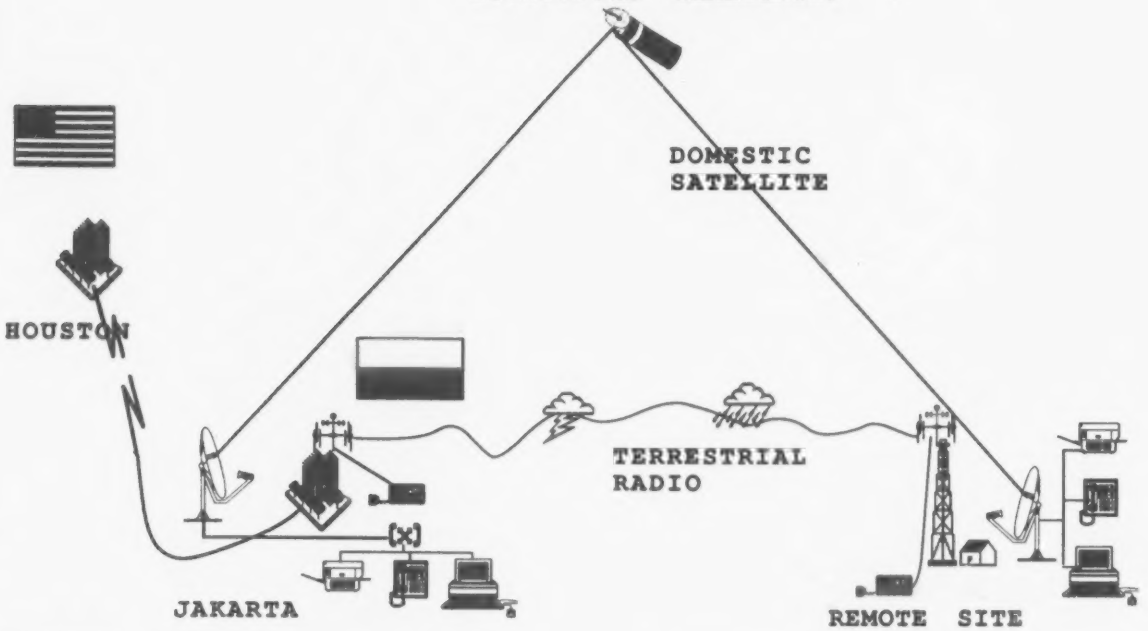
During Slot #1, the PCSI units apportion the 64 KBps circuit for 28.8KBps data and 38.4KBps voice.

Remote LAN Interconnection:

For discussion purposes, assume that the entire data capacity is dedicated to linking the Houston (see Sheet Six) and Jakarta (see Sheet Eight) LANs. Operating at 28.8 KBps, the HOU-JKT LAN link supports the small number of users in the Jakarta Office, and at remote sites.

SHEET FOUR ©1991 Infosat Telecommunications Ltd.

LOGISTICAL CHALLENGES

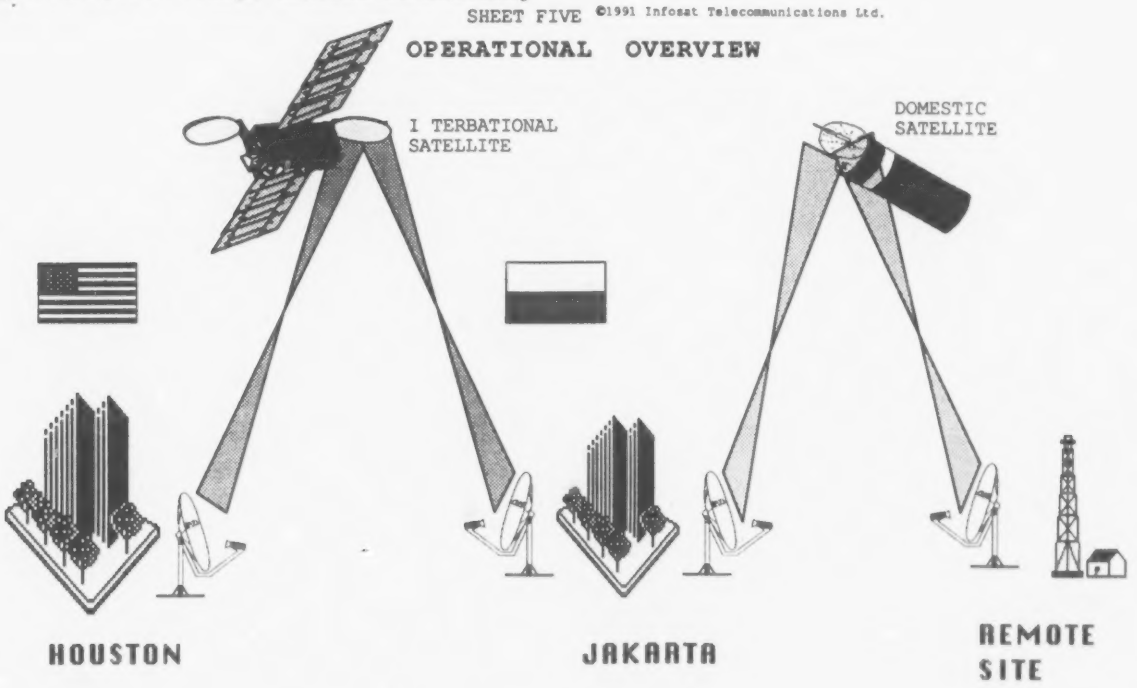


The PCSI units, using menu-driven software commands, may be manually configured for any data rate from either Houston or Jakarta Offices.

PCSI voice ports are individually configured, under software control, for data rates from 6KBps to 32KBps. Ports operating at >14KBps exhibit outstanding voice quality and are best suited for applications involving two satellite hops (as shown on Sheet Five which depicts the Houston-Remote Site communications path.)

SHEET FIVE ©1991 Infosat Telecommunications Ltd.

OPERATIONAL OVERVIEW



High Quality Speech:

In order to minimize speech-quality degradation due to compounded voice compression, two 15KBps PCSI voice ports are allocated for HOU-Remote Site calls. This ensures that 2-Hop satellite voice demonstrates no noticeable quality degradation compared with terrestrial voice.

In most cases, where calls are made from within the Houston Office to a remote site, there is no PSTN interconnection. Unencumbered by the uncertainties arising from PSTN interconnection, the PCSI units, configured for operation as if in a closed system, perform minimal signal processing of transmitted speech. This ensures that 2-Hop satellite voice does not exhibit noticeable processing artifacts such as centre-clipping, echo, background noise, etc.

The PCSI voice ports support standard 4-wire telephone interfacing, (see Sheet Eleven) thereby eliminating the need for 4/2 wire conversion at the Jakarta and Houston switches. This minimizes speech quality degradations due to echo and poor transmission level settings.(3)

For remote-site calls made from within the Houston Office, the speech quality, in terms of levels, noise, echo, and centre-clipping is comparable with domestic PSTN fibre. Given this excellent voice circuit performance, callers quickly adjust to satellite transmission delay.

For remote-site calls made from the US PSTN (see Sheet Twelve), the degradation in speech quality may range from unnoticeable to barely acceptable. The degree of deterioration depends on the consistency of Houston Office and Subscriber Line interconnections to the US PSTN or other VNETs (see Sheet Seven).

Digital Connection to US PSTN:

The Houston Office uses a digital interface for connection to the local PSTN Central Office (C.O.). For PSTN calls, the Houston Office Switch creates a 4-wire digital path between the PCSI unit and the local C.O..

The use of the digital (as opposed to traditional analog) C.O. interface ensures the consistency of Houston

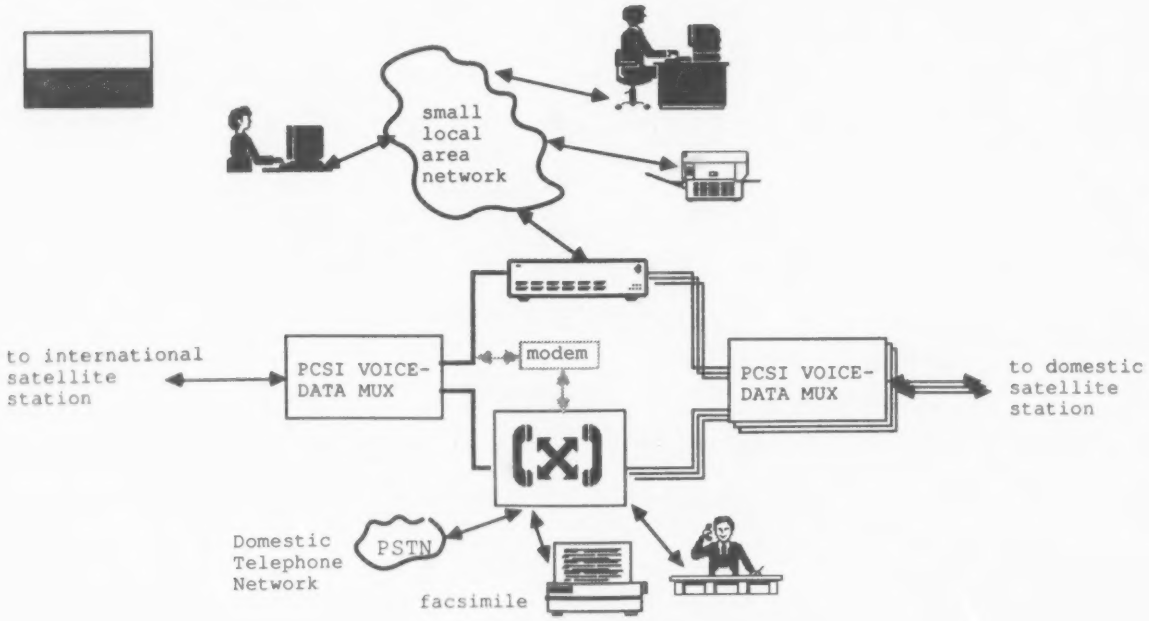
JAKARTA OFFICE CONFIGURATION



JAKARTA OFFICE

Office to local PSTN C.O. connections in terms of transmission levels, return loss, and channel noise. This eliminates variations in the quality of satellite-interconnected PSTN calls due to "bad" C.O. trunks.

The 4-wire (as opposed to 2-wire) C.O. interface eliminates the process of 4/2-wire conversion at Houston Office Switch, followed by a 2/4-wire conversion at the local PSTN C.O. Each of these conversions introduces an impedance mismatch, causing transmission losses (decreased Signal to Noise Ratio;SNR) as well as power reflections (echo) in 2-wire C.O. interfaces.

The 4-wire transmission path between the PSTN C.O. and the Houston Office Switch removes two sources of circuit impairment. Similarly, the PCSI unit's support of a 4-wire (as opposed to 2-wire) interface with the Houston Office Switch removes two more impairment sources.

By configuring the Houston Office Switch to support (a) digital C.O. interface and (b) 4-wire PCSI connection, five sources of circuit impairment are eliminated. As a result, PSCI unit connection to the local PSTN C.O. has the same speech quality as the Houston Office Switch.

Digital Transmission to PSTN C.O.'s:

The US PSTN is being rapidly upgraded to digital transmission using digital C.O.s. As a typical example, Indiana Bell, recently retiring it's last electromechanical C.O., already provides digital service to 47% of it's subscribers.(4) Therefore, calls to many PSTN C.O.s are handled in the original digital transmission format used by the Houston Office Switch.

Digital transmission to PSTN C.O.'s eliminates speech quality degradation due to A/D & D/A conversion, analog trunk noise, poor return-loss, and variations in transmission levels. These impairments, inherent in Analog networks, represent the major sources associated with transmissions between PSTN C.O.s.

The Houston Office Switch is configured to provide a transparent 4-wire digital interface between the PCSI unit and the US PSTN. Satellite interconnected calls made to any digital C.O. in the US PSTN suffer no transmission impairments up to the subscriber loop.

Analog Subscriber PSTN Connection:

Digital transmission between the Houston Office Switch and most US PSTN C.O.s leaves 2-wire analog subscriber lines (local loops) as the prime source of speech quality degradation in PSTN-interconnected calling.

A/D & D/A conversion distortion, Analog noise, poor return-loss, and variations in analog transmission levels are the major contributors to speech quality impairments in a digital network with digital C.O.s using 2-wire analog subscriber lines. Drawing from almost a century of expertise, the US Telephone Companies have learned to design and maintain C.O. Equipment and Outside Plant to provide an exceptional level of service using 2-wire analog loops. Unfortunately, this level of service extends only up to the subscriber's premises. Subscriber-supplied apparatus, such as low-cost telephones, office key-systems, and cordless phones, routinely fail to comply with PSTN specifications. Presently, this is a major factor in speech quality degradation for PSTN-interconnected satellite calls.

Digital Loops; Nearing Optimal Speech Quality

The US Telcos' steady introduction of digital services to business subscribers is beginning to expand into residences. These digital services eliminate the degradation caused by analog loops, thereby improving the quality and consistency of calls involving satellite interconnection to the US PSTN.

The US Telcos have already begun installing fibre from the C.O. to subscriber premises. By the year 2000, over 40 million US telephones will be served by fibre. (2)

DSP-based Telephones; Improving Loop Performance:

The use of sub-spec subscriber apparatus will wane rapidly with the advent of "intelligent services", such as caller identification, offered by the US Telcos. A new bread of DSP-based (Digital Signal Processor) telephone products will actually enhance 2-wire analog line performance through noise cancellation, transmission level correction, and return-loss impedance matching.

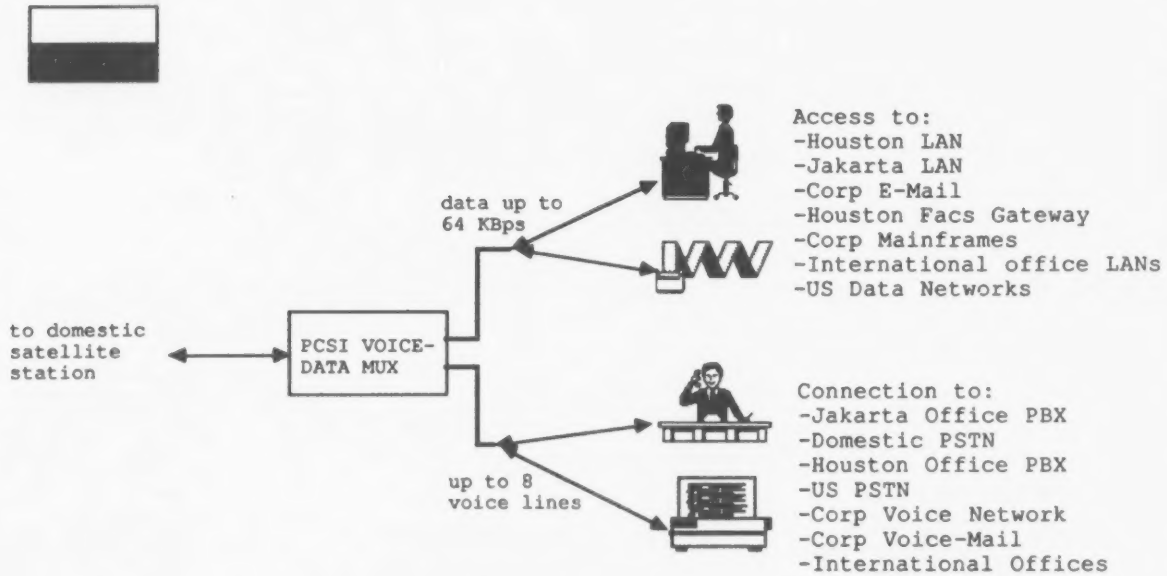
As the precursor to ISDN, DSP-based telephones will enhance the performance of 2-wire analog subscriber lines, making the speech quality of US PSTN-interconnected and internal Houston Office satellite calls virtually identical.

interconnecting through the Houston Office Switch, deliver optimal speech quality when calling the Jakarta Office and/or Remote Site(s).

SHEET NINE

©1991 Infosat Telecommunications Ltd.

REMOTE SITE CONFIGURATION



REMOTE SITE

Cellular Interconnection; Echo-Free:

Cellular telephones, employing a 4-wire interface for interconnection to the US PSTN, do not use the 2/4 & 4/2-wire hybrid converters required in 2-wire analog subscriber loops. Sheet Twelve depicts a Cellular Telephone {1} given 4-wire interconnection to the digital US PSTN. The digital interface between the US PSTN and HOU Office Switch enables seamless 4-wire transmission up to the PCSI Voice/Data MUX shown in Sheet Six.

This network configuration maximizes the benefits available from cellular's 4-wire interconnection to the US digital PSTN. With service throughout urban USA, cellular telephones,

Echo-Cancellation; A 2-wire Reality:

Many non-cellular PSTN interconnections, using 2-wire analog subscriber loops, suffer degradations in the form of far-end echo, speech clipping, and low transmission levels.

Far-end echo, heard mainly by the Jakarta & Remote parties, is the result of impedance mismatches at the US PSTN subscriber loop 2/4/2-wire hybrid converters. These hybrids cause some of the far-end parties' voice energy to be reflected back along the return speech path. Delayed approximately 1/2 second by the round-trip over each satellite, this reflected energy appears as an "echo" to Jakarta & Remote callers.

The PCSI Voice/Data MUX's use leading-edge DSP technology to provide adaptive echo-cancellation. Despite the recent improvements in their technical capabilities, echo cancellers provide optimal performance only under specific operating conditions.

Considered to be more of an art than a science, echo canceller programming involves the balance of Rx & Tx TLPs, plus the activation/inhibition of signal processing functions including centre-clipping, noise filtering, and return speech cancellation.

PCSI units provide interactive programming of these echo-canceller functions for each voice port in the network. This enables dynamic configuration of voice ports in response to network conditions.
The importance of high quality US PSTN interconnection is clearly demonstrated in an example. Let us suppose the very real probability of an hour long teleconference held at 10am Jakarta time (8pm Houston time), involving five managers; one in the Jakarta Office, another at a remote site, and the remaining three at various US PSTN-connected telephones.

This meeting would simply not be practical without digital PSTN-interconnection.

SUMMARY

As demonstrated by this case study, the combination of international and domestic satellite systems provides a very effective means by which

corporations can extend their international voice and data networks into developing nations.

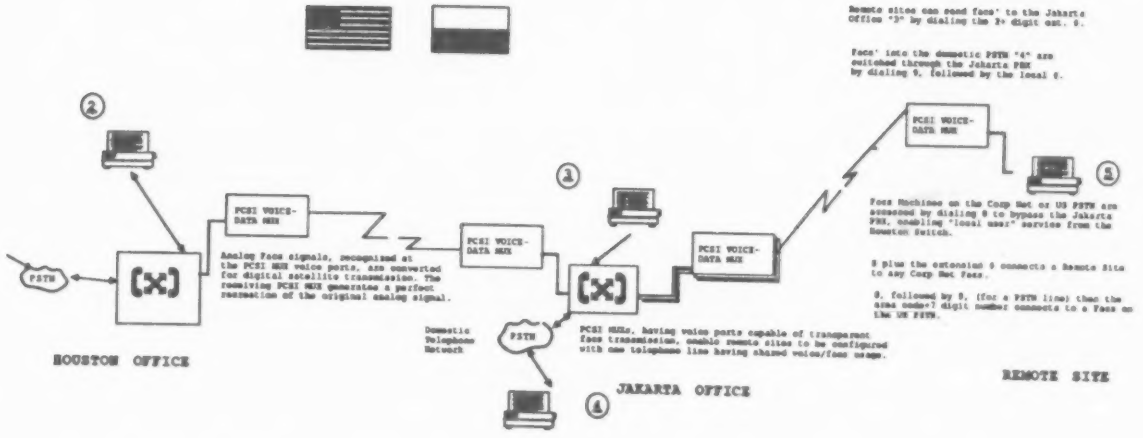
FACSIMILE OPERATION



COMPACT DISC QUALITY INTERNATIONAL AUDIO DISTRIBUTION AT C- OR KU- BAND

PAUL A. STERN AND KAY M. NORTON
COMSAT WORLD SYSTEMS
WASHINGTON, D.C.

The authors wish to acknowledge the invaluable assistance of John Phipps and William Sandrin of COMSAT Laboratories in the drafting and editing of this paper.

Abstract

Fixed satellite distribution of high-quality digital audio service is available now. Unlike mobile applications, which may ultimately be provided directly from the satellite to hand-held receivers, fixed distribution would be provided to small C- or Ku-band antennas located at or near existing radio stations for rebroadcast at AM or FM, direct to hotel rooftop antennas or to cable headends for rebroadcast on existing cable networks.

1.0 Introduction

At the outset, it is important to distinguish digital audio distribution service from its more well-known relation, digital audio broadcasting (DAB) service. The term DAB is generally used to refer to direct-from-the-satellite L-band transmission into small handheld or car receivers. Although several U.S. companies have proposed DAB satellite networks, this service is not expected to be available for several years, pending development of receivers and resolution of several international and domestic regulatory issues.

The service discussed in this paper, digital audio distribution service, is multipoint distribution of high-quality audio, up to compact-disc (CD) quality, into small (e.g., 1.8 or 2.4 meter) fixed C- or Ku-band antennas. Unlike digital audio broadcasting service, this service is available now.

2.0 The Market

The small receive antennas for digital audio distribution service would typically be located at AM or FM radio stations, hotel rooftops or cable headends. Signals received by these radio stations would be rebroadcast at AM or FM; those received at hotels would be distributed throughout the hotel; and those received by cable headends would be distributed to listeners in much the same way that cable TV is distributed to viewers.

For listeners of programming rebroadcast at AM or FM, some of the frequency response advantages would be lost in the retransmission and thus CD quality reception is not presently possible. This will continue to be true until frequencies are set aside and receivers developed for digital audio reception. However, even in the case where the end product is analog, digital transmission is superior to analog for signal storage and long-distance distribution. The fewer conversions between analog and digital, the higher the ultimate signal quality will be.

Although AM and FM listeners must wait for CD-quality audio, cable radio subscribers can enjoy the full benefits of high-quality international digital audio immediately. Many listeners are already enjoying digitally delivered, commercial-free programming in domestic applications (including jazz, classical, country, rock, live concerts and sports). Service providers such as Digital Cable Radio, a partnership of Jerrold Communications and three top U.S. cable operators; and Digital Music

Express, a subsidiary of International Cablecasting Technology, are offering a 24-hour premium cable audio service featuring digital sound that is transmitted to subscribers' stereo receivers via their cable television systems.

3.0 Principles of Compression

The ideal range of human listening is 20 - 20,000 Hz with loudness sensitivity varying by frequency. The digital audio coders currently being marketed divide this range into a large number of smaller bands based roughly on the acoustic response of the human ear. These individually coded smaller bands are transmitted with an error protected control word which is used to reconstruct the input signal in the decoder.

This coder technique can be more easily understood when considered in the context of a single piano note. For example, the fundamental frequency of the D_6 key on a piano is about 1175 Hz. When the key is struck and the note passed through a coder, only the frequency band which contains those narrow tones associated with the D_6 key are activated. Slight coding inaccuracies which result in low-level noise are limited to the same space already occupied by the much louder D_6 note, which effectively "masks" this noise.

By using sophisticated source coding/compression techniques, the space segment required for transmission of high quality signals can be dramatically reduced. For example, the recently adopted ANSI standard for audio encoding (ANSI T1.305-1990) requires a 384 kbit/s transmission rate per monaural channel for program audio with a 15 kHz bandwidth. With currently available compression equipment, this same transmission could be accomplished at a transmission rate of 64 to 128 kbit/s.

Several organizations have developed algorithms for identifying inaudible sounds. The most tested and documented algorithms include the Masking-Pattern Universal Sub-band Integrated Coding and Multiplexing system (MUSICAM), Audio Processing Technology, and two proprietary systems developed by Scientific Atlanta and Dolby Laboratories. These algorithms operate at multiple bit rates, providing flexibility between audio quality and transmission bandwidth.

Manufacturers have incorporated these algorithms into a range of audio products which deliver very high-quality sound at a relatively low cost, while also providing sophisticated network management and control capability.

Table 1 below summarizes the features of the various algorithms. Table 2 provides information regarding currently available audio codecs incorporating these algorithms.

4.0 Quality of Service

While some argue that the quality of FM radio is adequate and that CD-quality audio transmission is unnecessary, it is likely that the public will ultimately demand higher-quality fidelity for both voice and music transmissions. Compact discs and digital audio tapes are becoming increasingly popular for home and automobile use, and consumers will not likely be comfortable stepping down in quality when listening to the radio. In this respect, the radio broadcast industry now lags behind the video broadcast industry, where a higher quality is available over the air than is available for home video viewing.

While available compression technology makes possible the transmission of CD-quality sound with lesser amounts of spectrum, it is important to keep in mind that not all customers will require compact disc quality. Instead, various customers will require different grades of service depending upon the market area, audience and type of transmission. For example, listeners of news, sports and information programming will likely be satisfied with lower fidelity than listeners of music.

Based upon the prevalent standards in the professional and consumer audio industries, four important grades of audio service have been identified. These grades are commonly characterized by the following quality attributes:

a. Transparent CD Quality Service: The required audio signal bandwidth for this grade of service is a 20 kHz channel. Typical transmission rates are approximately 192 to 256 kbit/s per monaural channel, with a required bit error rate of less than 10^{-8}. Signal to quantization noise ratio of greater than 90 dB is expected.

b. Near CD quality service: The required audio signal bandwidth for this grade of service is a 15 to 20 kHz channel. Typical transmission rates are approximately 128 kbit/s per monaural channel, with a required bit error rate of less than 10^{-7}. Signal to quantization noise ratio of between 65 and 90 dB is expected.

c. Broadcast FM Quality: The required audio signal bandwidth for this grade of service is a 15 kHz channel. Typical transmission rates are approximately 64 to 128 kbit/s per monaural channel, with a required bit error rate of less than 10^{-6}. Signal to quantization noise ratio of approximately 60 dB is expected.

d. Broadcast AM Quality: The required audio signal bandwidth for this grade of service is a 5-7 kHz channel. Typical transmission rates are approximately 64 kbit/s per monaural channel with a required bit error rate of less than 10^{-5}. Signal to quantization noise ratio of approximately 45 dB is expected.

Table No. 3 below summarizes the key attributes of each type of quality discussed above.

The signal to noise ratio of greater than 90 dB associated with "transparent" CD quality audio is needed in order to accurately recreate the dynamic range of the analog source. As a practical matter, it is extremely difficult to achieve this standard, particularly for more highly compressed systems. Thus, while several audio codec manufacturers claim to be delivering true, i.e. "transparent" CD-quality, purists argue that what is actually being delivered is "near" CD quality with a signal to noise ratio of 90 dB or less.

In August 1991, at the Satellite Communications Users Conference in San Jose, California, COMSAT World Systems conducted a live satellite demonstration comparing various audio codecs against each other and against uncoded audio. Scientific Atlanta, Dolby, LNR and Intraplex all participated in the demonstration, each representing one of the four principal compression algorithms. A digital audio tape recorder was used as source material for all four digital audio systems. Various music and speech samples had been previously recorded onto the DAT from the compact disc. The DAT source material was then routed through each coder and transmitted via the INTELSAT 174 ° east satellite using a 2.4 meter transportable antenna. The

TABLE 3. AUDIO CODEC CHARACTERISTICS

Quality	Typical Coding Techniques	Channel Bandwidth (kHz)	Transmission++ Rate (kbit/s)	SNR *	Minimum BER +
CD	Waveform	20 kHz	192 - 256	> 90	< 10-8
Near CD	Parametric	20 kHz	128 - 192	65	< 10-7
Broadcast FM	Parametric	15 kHz	64 - 128	60	< 10-6
Broadcast AM	Parametric	5 - 7 kHz	24 - 64	45	< 10-5

* Signal to Noise Ratio in dB + Minimum bit-error rate, assuming no FEC ++ Per Monaural Channel

four signals were received using the same antenna and fed into the decoder and ultimately into a central switcher, allowing demonstration participants to directly compare each signal and the DAT source. Figure 1 below is a block diagram of how this demonstration was configured.

Although listeners to the San Jose demonstration were told in advance whether they were listening to coded or uncoded audio, many audio experts and most casual listeners indicated that they heard no difference between the two audio sources or between the various algorithms. In "blind" tests given by Scientific Atlanta and others, where listeners were asked to distinguish between coded and uncoded audio, very few were able to do so on more than a random basis. Thus as a practical matter, the term "CD quality" has become synonymous with both near and transparent CD quality.

5.0 System Design and Spacecraft Capacity

The design of an economically practical digital audio service via satellite requires careful consideration of a number of system parameters, including transmission rate, receiving earth station size, availability, modulation and coding.

The most efficient system design is to optimize the entire transponder for digital audio services. This results in the least amount of bandwidth per channel and thus the greatest number of channels per transponder. When the transponder is operated under a shared arrangement there will be constraints placed on the system by the other carriers.

FIGURE 1. BLOCK DIAGRAM OF COMSAT DIGITAL AUDIO DEMO - AUGUST 1991

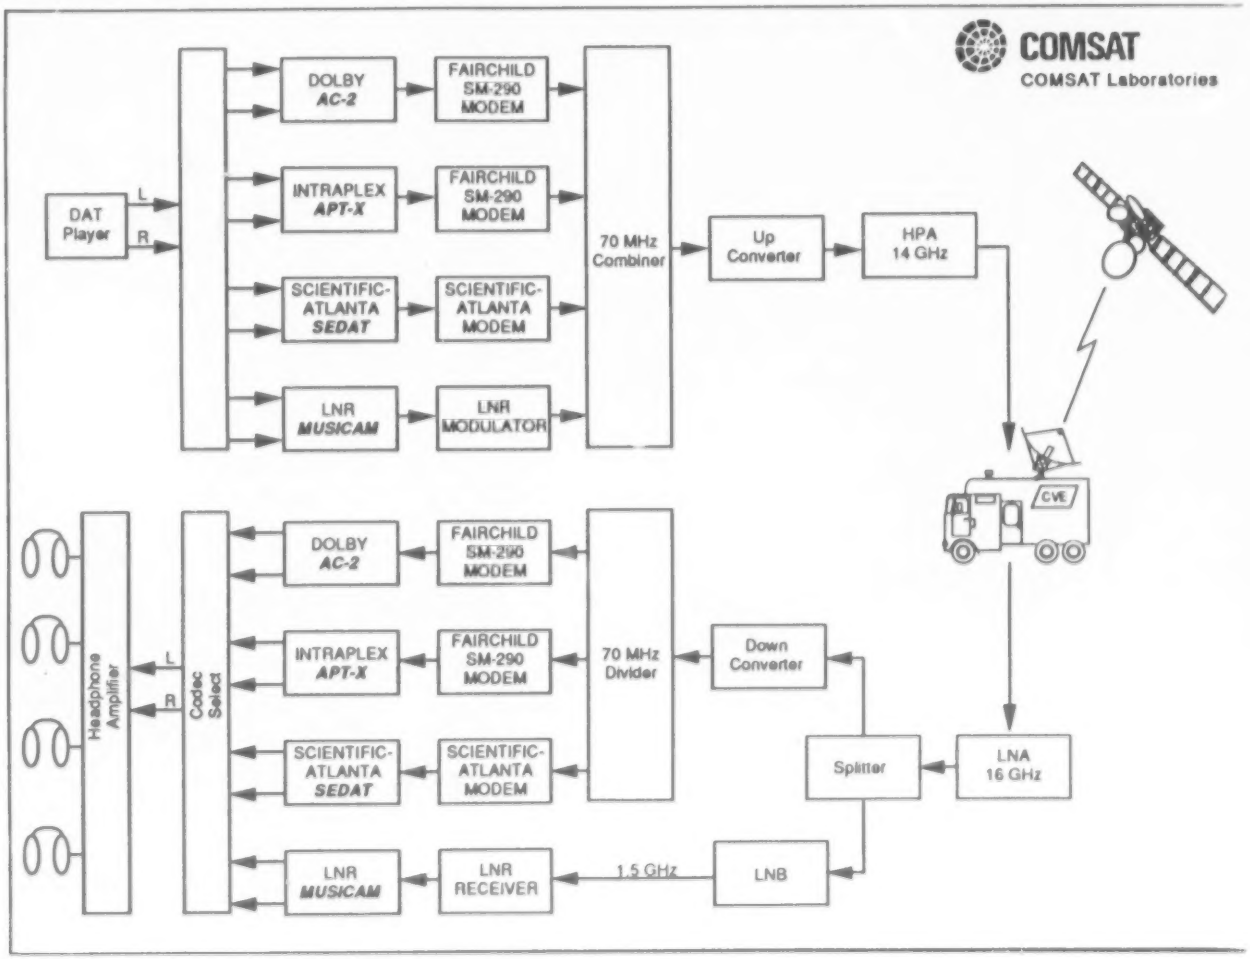

Table 4 below summarizes capacity calculations under an optimized scenario.

As can be seen from Table 4, transmission via the INTELSAT-K satellite, expected to be in operation in the Atlantic ocean region by mid-1992, could yield 239 CD-quality stereo channels into a 5.5 meter antenna, 204 channels into a 3.5 meter antenna, 121 channels into a 1.8 meter antenna, and 70 channels into a 1.2 meter antenna, based on a 5 dB system margin. This chart is based on an optimized system design and the use of a special codec design suggested by COMSAT Labs, which uses additional outer coding techniques.

Table 4 also reveals the sensitivity of digital audio networks to the size of the receive antennas and the assumed system margin, which is required as protection against rain impairments. In most digital audio networks, margin selection will be somewhat complicated by the point to multipoint nature of the service, where some receiving earth stations may be in climates much different than others. Because excess margin translates into additional spacecraft resources, it would probably be wise to select a baseline margin based upon nominal or representative propagation conditions, and then require receiving earth stations located in areas of severe rain impairments to use larger receive antennas.

TABLE 4. SUMMARY FOR THE OPTIMIZED SERIES OF SYSTEM CAPACITY CALCULATIONS EXAMPLES

	Number of DAB channels			
	5	2.9	1.8	meters
IS V (72 MHz, High)	79	36	15	
IS V (72 MHz, Low)	79	30	12	
IS VA (72 MHz, High)	78	36	16	
IS VA (72 MHz, Low)	79	34	13	
IS VI (72 MHz, High)	121	51	25	
IS VI (72 MHz, Low)	121	50	22	
C-band (3 dB system margin)				

	5.5	3.5	1.8	1.2	meters
IS V/VA (72 MHz, High)	105	57	29	17	
IS V/VA (72 MHz, Low)	116	59	29	16	
IS VI (72 MHz, High)	175	110	45	31	
IS VI (72 MHz, Low)	182	119	45	31	
IS K (54 MHz, High)	50	50	42	34	
IS K (54 MHz, Low)	188	136	63	39	
Ku-band (7 dB system margin)					

	5.5	3.5	1.8	1.2	meters
IS V/VA (72 MHz, High)	182	121	46	28	
IS V/VA (72 MHz, Low)	182	121	46	28	
IS VI (72 MHz, High)	242	182	82	49	
IS VI (72 MHz, Low)	273	182	84	49	
IS K (54 MHz, High)	110	104	81	57	
IS K (54 MHz, Low)	239	204	121	70	
Ku-band (5 dB system margin)					

In addition to receive earth station size, the gain setting of the satellite and the uplink power will also impact upon system margin. As shown in Tables 4, in some instances, capacity is dramatically increased by using the low gain setting on the satellite which requires use of more uplink power without saturating the transponder. For example, assuming optimized system design with 7 dB system margin, switching the INTELSAT-K satellite from the highest gain to the lowest gain high to very low gain setting more than triples (from 50 to 188) the number of CD quality channels that can be transmitted into a 5-meter antenna.

6.0 Digital Audio Distribution Service in the Pacific Ocean Region

The linguistically, politically and culturally diverse countries of the Pacific region make up the fastest growing and perhaps the most dynamic media market in the world. This market ranges from the limited broadcasting systems in Cambodia and North Korea, where radio is the main source of information, to the multi-channel video services available in Japan, Australia and Thailand. Several Pacific countries have cable networks and pay-TV services, and most offer satellite-delivered programming.

While direct-to-cable premium audio services are likely to be first implemented in the Pacific region by countries with the fastest growing economies, other forms of digital audio distribution service are also well suited to the region. For example, "narrowcasting" -- transmission of programming aimed at relatively small cultural, religious or other audiences -- is ideal for an area as culturally diverse as the Pacific region.

Another potentially lucrative market for the Pacific region is the distribution of Western programming to hotels. News and entertainment tailored for tourists and business travelers could be received directly from the satellite using small roof-top antennas.

Direct-to-home reception of high-quality audio will become more feasible for the Pacific region with the development of even smaller (less than 1 meter) receive-only dishes which can be wired directly into a home stereo receiver. This form of audio distribution is similar to the direct-to-cable market -- allowing CD-quality programming to be transmitted directly to the listener.

The U.S. and Europe will likely lead in the proliferation of high-quality digital audio services over satellite. However, as the marketplace and regulatory environment evolve, these types of radio services may become increasingly available in the Pacific region as well. In the meantime, Communications Agencies and Licensed Radio Operators can take advantage of the economies provided by digital compression and transmission techniques by offering a diversity of music, news, weather and entertainment programming to Pacific region audiences.

7.0 Conclusion

Development of audio compression equipment is making transmission of high- quality digital audio via satellite economically attractive. Several providers of domestic cable-delivered digital radio programming have proposed expanding their network to points in Europe via the INTELSAT system and it is likely that before the end of 1992, many European listeners will have as many as 60 channels of commercial-free CD quality music available to them. Until direct-to-receiver DAB services become technically and economically feasible (and even afterwards for certain urban and other regions), broadcasters should consider use of COMSAT's digital audio distribution service for transmission of high quality audio programming.

Cable Network in the Pacific and Asia Region and Optical Submarine Cable Technology

Hitoshi Yamamoto
Yoshihiko Yamazaki

Submarine Cable Systems Department
Network Development Headquarters
Kokusai Denshin Denwa Co.,Ltd.(KDD)

The number of optical submarine cables in the Pacific and Asia region is growing rapidly these days. This trend could be interpreted as the effort to achieve the integration of the Pacific and Asia region. Furthermore, this trend has been expanding in the world to form global network. This paper reviews the present status of optical submarine cable network in the Pacific and Asia region and its technologies.

1. Introduction

Development of optical fiber submarine cable systems commenced in the late 1970's at various countries taking into account the growing demands for more advanced telecommunication services and remarkable progress in optical transmission technologies. Through the prototype manufacturing and various evaluation tests including field test of repeaters and cables, optical fiber submarine cable systems were confirmed to be of practical use.

As a result, optical fiber submarine cable systems were decided to be used in the Hawaii Cable No.4/Transpacific Cable No.3 (HAW-4/TPC-3) which were put into service in 1989 as the first long-haul international optical fiber submarine cable systems in the Pacific and Asia region.

In succession of HAW-4/TPC-3, Guam-Philippine-Taiwan cable (G-P-T), Hong Kong-Japan-Korea cable (H-J-K) were put into service in 1990, and construction of Transpacific Cable No.4 (TPC-4), ASEAN Optical Fiber Submarine Cable Network (AOFSCN), PacRim East/West and APC are now in progress. Furthermore, TPC-5 Cable Network are planned to be constructed in the middle of 1990's with new technologies and restoration arrangement.

This paper reviews the present status of optical submarine cable network in the Pacific and Asia region and its technologies.

2. Cable Network in the Pacific and Asia Region

Since the optical fiber submarine cable system can provide high quality, high reliability and large capacity digital transmission, construction of the optical submarine cable network is being promoted extensively.

So far, over 30,000km of optical submarine cable including HAW-4/TPC-3, G-P-T, H-J-K and NPC are now in service, and the construction of over 40,000 km optical submarine cables including TPC-4, AOFSCN, PacRim East/West and APC are in progress. Furthermore TPC-5 network, total length of 25,000 km, is now planned in the Pacific and Asia region.

Fig.1 shows optical submarine cable network in the Pacific and Asia region. Solid lines indicate optical submarine cables which are now in service and dotted lines indicate optical submarine cables which are now under construction or planning stage.

Those optical submarine cables improve the transmission quality of the international telecommunication and are expected to play a major role to construct the worldwide ISDN (Integrated Service Digital Network).

(1) HAW-4/TPC-3

HAW-4/TPC-3 consist of the TPC-3 cable linking Hawaii, Japan and Guam by a Branching Unit and the HAW-4 cable linking Hawaii and U.S. mainland.

TPC-3 cable is the integrated system of OS-280M system and SL-280 system using 1.3 um technology. Total system length is approximately 13,300 km (HAW-4; 4,200 km, TPC-3; 9,100 km) and repeater spacing is 50 - 70 km. The total cable capacity is 560 Mbps (7,560 channel - 64 Kbps/channel) for the HAW-4 cable with two working fiber pairs, and 280 Mbps (3,780 channel - 64 Kbps/channel) for each fiber pair between Hawaii/Japan, Guam/Japan and Hawaii/Guam in the TPC-3.

(2) H-J-K

H-J-K cable was put into service on May 1990, linking Hong-Kong, Japan and Korea by a Branching Unit. H-J-K cable is also the integrated system of OS-280M and SL-280. Total system length is approximately 4,600 km. The cable capacity is 280 Mbps (3,780 channel - 64 Kbps/channel) both for Hong-Kong -Japan, Korea-Japan. (There is no fiber pair between Korea and Hong-Kong.)

(3) ASEAN Optical Fiber Submarine Cable Network

In the ASEAN region, the construction of optical submarine cable network such as Burunei-Singapore, Burunei-Malaysia-Philippine etc are in progress. These ASEAN optical submarine cables will constitute an optical submarine cable network in the Pacific and Asia

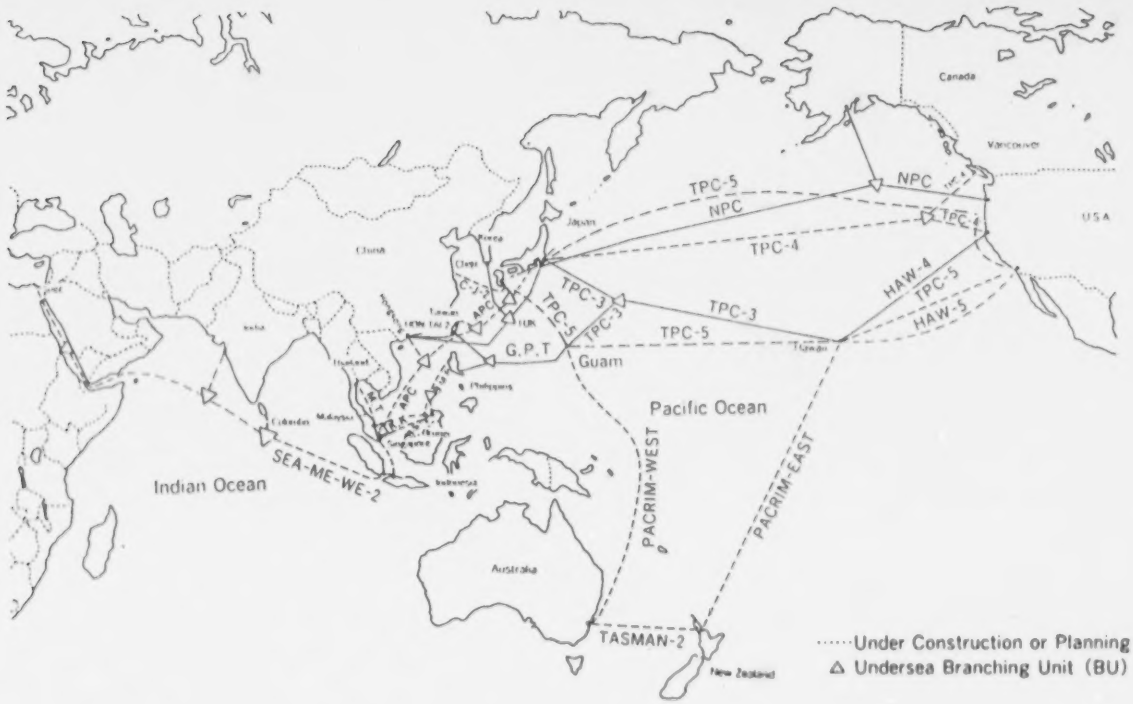

Fig.1 Optical submarine cable network in the Pacific and Asia region

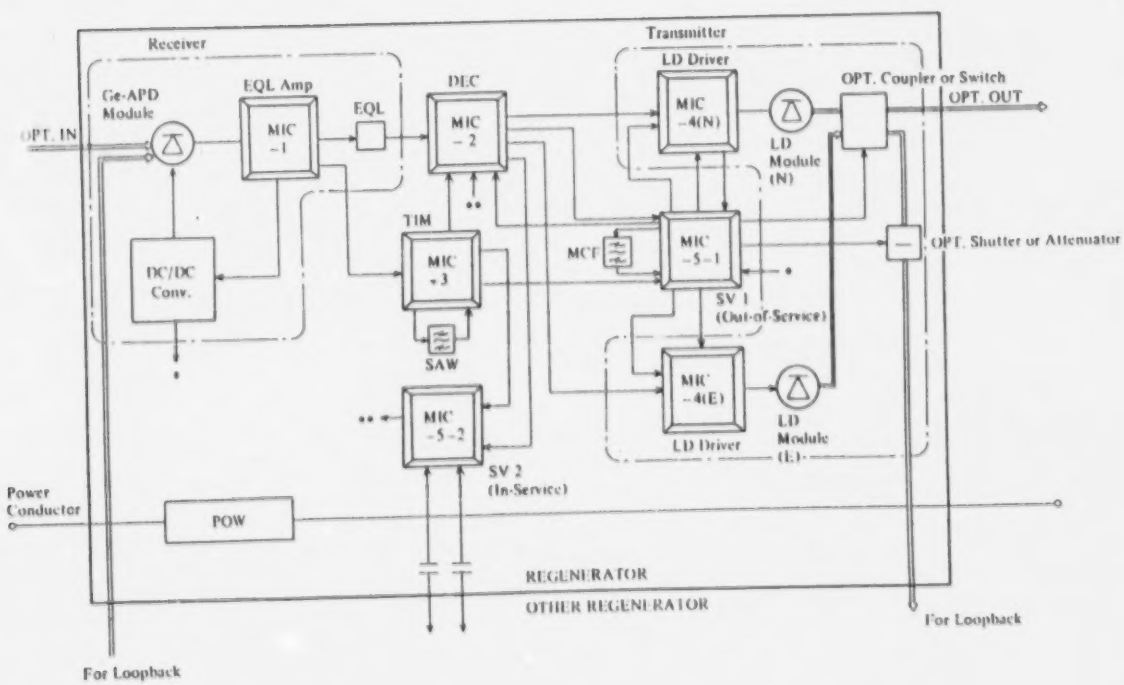

Fig.2 Regenerator circuit of OS-280M optical submarine repeater

region through connection with the HAW-4/TPC-3, H-J-K, APC and G-P-T cable etc.

(4) TPC-4

The construction of the TPC-4 cable which connects Japan with U.S. mainland and Canada by a Branching Unit is now in progress toward the Ready for Service date at the end of October 1992 to cope with the increase of telecommunication demand in the Pacific and Asia region.

The TPC-4 cable is the integrated system of OS-560M system and SL-560 using 1.55 um technology. Total system length is approximately 9,800 km and repeater spacing will be 130 - 150 km which is more than double of 280M systems thanks to the low loss fiber at 1.55 um wavelength. The total cable capacity is 1,120 Mbps (15,120 channel - 64Kbps/channel) with two working fiber pairs.

(5) PacRim East/West and TASMAN-2

The construction of the PacRim East/West and TASMAN cables are being conducted to meet the growing traffic demand between Australia/New Zealand and the Asia/North America/Europe. If either one of the PacRim East/West cables should fail, it can be restored by the other cable through the loop network formed by connecting the system with HAW-4/TPC-3 and TPC-4 cables in the North Pacific.

PacRim East is the integrated system of SL-560 system and S-560 system. PacRim West and TASMAN-2 will be constructed by S-560. Total system length is approximately 16,800 km (PacRim East; 7,700 km, PacRim West; 6,900 km, TASMAN-2; 2,200 km).

(6) APC

APC Cable is to link Singapore, Malaysia, Hong-Kong, Taiwan and Japan (Miyazaki, Miura) with four branching units and total length is 7,300 km. The construction of APC Cable is now in progress toward the RFS date of middle of 1993. APC cable system is the integrated system of OS-560M and SL-560.

(7) TPC-5 CN

TPC-5 Cable Network will link Japan, U.S. mainland, Hawaii and Guam in loop (25,000 km in total length) and each segment will contain working fiber pair and restoration fiber pair of 5 Gbps (60,480 channel - 64 Kbps/channel) By this configuration, traffic between any two points on this network can be carried on two different routes and thus can be restored at once if a fault occurs in this loop. Namely, TPC-5 CN will be constructed with a so-called self-healing concept in 1995/1996 and will be able to form a remarkably high quality and highly reliable cable network.

With regard to the technology aspect, TPC-5 CN will adopt Optical Amplifier technology with a transmission capacity of 5 Gbps which is currently under development.

3. Optical Submarine Cable Technology

(1) 1.3 um Wavelength Technology

Optical submarine cable systems using 1.3 um wavelength technologies are identified as the first generation optical submarine cable systems. The features of the first generation optical systems are that all operate at 1.3 um wavelength, where one of low loss bands in silica base optical fiber exists and dispersion became minimum, and as for the line bit-rate, 295.6 Mbps is adopted, which is based on CEPT-4 (139.264 Mbps).

The transmission bit-rate is 280 Mbps which provides 3,780 channel (64 Kbps/channel). These are used in TAT-8 which is the integrated system of SL-280, NL-2 and S-280, and TPC-3 which is the integrated system of SL-280 and OS-280M. Basic parameter of those systems such as optical wavelength, line current, line code and frame format are coincided so as to interconnect each other through the TAT-8 and TPC-3 integration development testing. The reliability target for long-haul submarine cable systems is less than three ship repairs over the 25 years of system design life. To meet this demand, the reliability test for the repeater components such as LD, APC/PIN diode, optical components and MIC have been carried out extensively[1], and several redundancy techniques are adopted. Fig.2 shows the highly integrated OS-280M optical submarine repeater circuit to follow the reliability objectives described above.

Regarding the optical submarine cable, long-term reliability and stable operation are essential under the high tension conditions during the cable laying/recovering and under the high pressure/low temperature condition on the deep sea floor in the practical use. Considering these requirements, optical submarine cables are designed to protect optical fibers from high water pressure and high tension force, and also optical fibers used in submarine cables are proof tested at an appropriate strain such as 2% in case of the OS-280M cable. Fig.3 shows OS-280M optical submarine cable (Light weight type). The average loss of the OS-280M cable is about 0.36 dB/km, and the repeater spacing is 50 km - 70 km[2].

(2) 1.55 um Wavelength Technology

Optical submarine cable systems using 1.55 um wavelength technologies, where optical attenuation of a silica based fiber is minimum, are identified as the second generation optical submarine cable systems.

Fig.4 shows the relationship between repeater spacing and transmission bit rate depending on the fiber type and LD type[3]. DFB LD, which has an excellent single mode characteristic, and 1.55 um cut-off wavelength shifted optical fiber, which has zero dispersion wavelength at 1.3 um, is a reasonable combination for up to 600 Mbps transmission because low loss

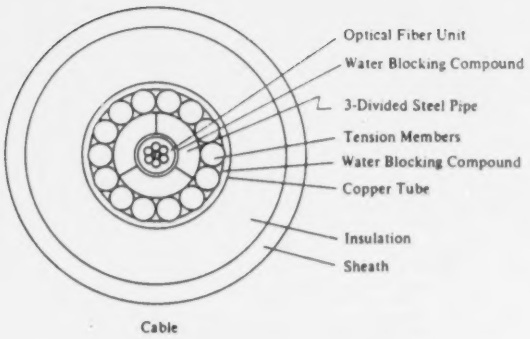

Fig.3 OS-280M optical submarine cable cross section

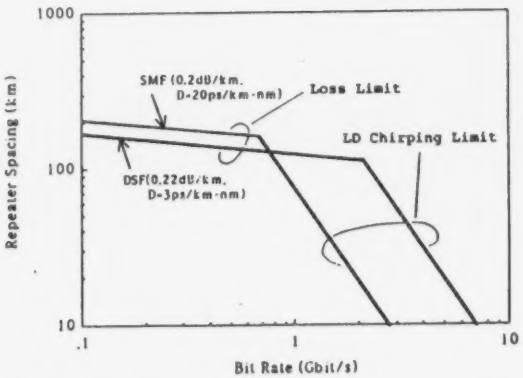

Fig.4 Relationship between repeater spacing and transmission bit-rate

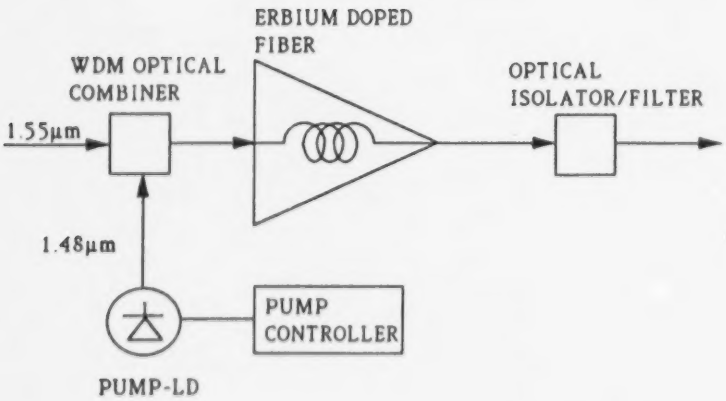

Fig.5 Schematic diagram of optical amplifier circuit

characteristics of silica based optical fiber can be made good use with a little mode partition effect.

OS-560M system, which is applied to the TPC-4, APC etc is based on the OS-280M system and following newly developed technologies are adopted.

a) 1.55 um optical transmitter/receiver
b) Low loss optical fiber
c) High speed MIC
d) Repeater supervisory circuit
e) Transmission Terminal Equipment using block synchronous multiplexing
f) Repeater housing and cable coupling

OS-560M cable design is same as that of OS-280M cable except its optical fiber. In order to get lower loss optical fiber, a pure silica core type fiber is adopted. The average loss of about 3,000 km length of manufactured cables is 0.180 dB/km at 1.55 um[4].

Optical transmission power and receiving sensitivity of OS-560M repeater are -1.4 dBm and -38.4 dBm in average, respectively. 130 km - 150 km of repeater spacing is attained thanks to the above cable and repeater characteristics[5].

Similar to the 280 Mbps systems, the basic parameters of 560M systems are also coincided so as to inter- connect each other in the TPC-4 and TAT-9.

(3) OA Technology

Taking into account the demand of the larger capacity optical submarine cable system, the optical amplifier (OA) technologies have been developed over the past few years in place of conventional regenerative system. There are three types of optical amplifiers, that is, a semiconductor laser type, a fiber Raman type and a fiber laser amplifier type[6]. As for the semiconductor laser type, 30 dB gain can be achieved, but its gain depends on the polarization status and coupling loss to fibers is high. As for the fiber Raman type, higher pump power is required and this type will be suitable in non-repeatered system as a booster and a pre-amplifier rather than repeatered system. The fiber laser amplifier using Er^{3+} doped fiber also needs pump power, however, it can be smaller than pump power in the fiber Raman type. The coupling loss to the transmission fiber is small and polarization dependence is also small. The Er^{3+} doped fiber amplifier is considered to be most practical optical amplifier for the submarine cable use. In the OA system, optical signals are directly repeatered without conversion to electrical signals in the repeaters. This means OA repeater will be composed without high speed electronics. The OA system will have the following features.

a) Simple repeater composition
b) Only low speed electronics in the repeater
c) SDH (Synchronous Digital Hierarchy) compatible
d) Bit rate transparent and free from modulation scheme repeater

Fig.5 is a schematic diagram of OA repeater circuit. OA submarine cable system is expected to be applied to TPC-5 CN in 1995 - 1996. So far, recirculating testing was conducted and successful 9,000 km transmission experiment at 5 Gbps transmission speed have been confirmed. This means that feasibility of transoceanic transmission at 5 Gbps is more surely confirmed.

4. Branching Technology

Branching technology is one of the special feature in the optical submarine cable system which was not realized in the coaxial submarine cable system.

Optical submarine cable can accommodate multiple fiber pairs. Consequently, in the cable system, it is now possible to design a device, branching unit, which allows the transmission paths to be split and branched to separate landing stations. This means the branching technology allows us to make more flexible cable planning. APC will have four branching units which will connect six landing points.

Fig.6 shows OS system branching unit which was introduced in the TPC-3. OS system branching unit can provide two features, which are useful in the cable fault condition. One is optical path reconfiguration function and the other is power path reconfiguration function. Namely, one of the branch cable has a fault, service will be re-established using the above two features in the branching unit between the main cable and the other branch cable.

5. Cable to Cable Restoration

In the era of optical submarine cable, service restoration becomes more important than ever before because of the expansion of the large capacity optical submarine cable network and the requirement to minimize the transmission delay. Until now, it was usual to use satellites for back up when cable circuits failed. However, cable capacity in the optical submarine cable become large and it become difficult to keep enough satellite circuits to back up cable circuits. Furthermore, optical submarine cables provide high quality, high reliability and wideband digital transmission circuits which are expected to be applied to data communication, video transmission etc. Users of high speed digital circuits are demanding services via optical submarine cables because of their small transmission delay and high quality, and further they request services complemented and restored mutually by optical submarine cables. The need for cables to back up each other is therefore recognized.

In the TPC-5 Cable Network planning, these requirements are taken into account and TPC-5 cable network will provide restoration facilities in itself.

Fig.6 OS system branching unit

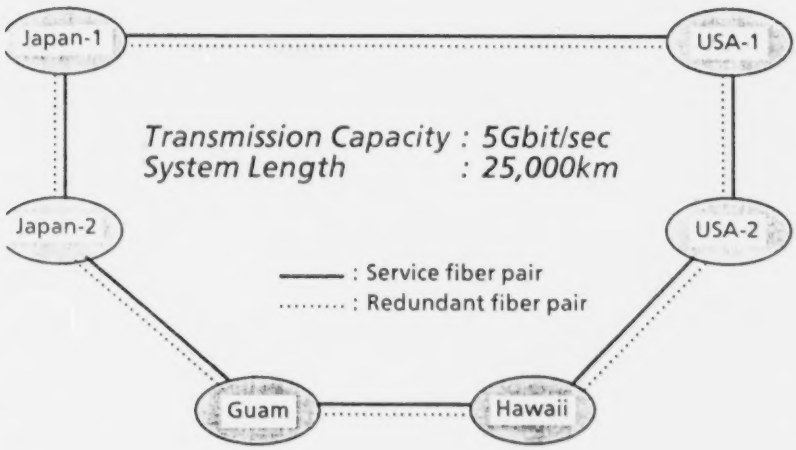

Fig.7 TPC-5 Cable Network configuration

Fig.7 shows TPC-5 Cable Network configuration. Straight line indicates service fiber pair and dotted line indicates restoration fiber pair.

6. Conclusion

This paper describes present status of optical submarine cable network in the Pacific and Asia region and technologies applied in the system. Technologies advancement of the optical submarine cable occurs rapidly owing to the requirements of high reliable/high quality/high capacity transmission. As a result the cable network in the Pacific and Asia region is being expanded rapidly.

7. Acknowledgment

Kuala Lumpur

1.0 Abstract

Optical fiber submarine cable transmission system has emerged as the most economical system for transmitting large amount of digital information in the telecommunication fields. It offers high transmission capacity and quality, low propogation delay, high reliability and security. It is estimated that by 1996 world invesment in optical fiber submarine cables will exceed US $ 11 billion. More than half of this investment will be in the Asia - Pacific Region. It is a well known fact that the Pacific Ocean Region (POR) countries have been extensively connected by optical submarine cables and there are still few projects in que to be implemented. The South East Asia Nations (ASEAN) are also in the race towards efficient global communications and have plan to interconnect all ASEAN countries by submarine optical link by the end of 1994. This network when interconnected to the POR network will begin a new era in telecommunications between the two regions. This paper will present the detail plan of the AOFSCN and its contribution towards a global digital link.

2.0 The Need For a Global Telecommunications Network

The initial trend of economic growth of most Far-East countries was based on inexpensive land and labour, and the abundant natural resources present. Now it has shifted towards manufacturing these resources locally into finished goods. This phenomena is clear from the fact that the internal manufacturing process in these countries have grown dramatically.

However, manufacturing growth requires both international and regional telecommunications. A good communication infrastructure is also needed by the trading and banking services supporting the manufacturing process. So, it is true to say that communications technology will play a vital role in the development of regional and international economies.

In response to intensifying competitive pressures in the global business environment, industry is undergoing a transformation from a rigid hierarchical orientation to a horizontal structure that crosses national boundaries. Increasingly, decisions are being made from a global framework. These decisions can range from a financial transaction to be executed on any one of the bourses in the world, to an operational strategy that allows factories in Europe to handle overflow from other parts of the world.

Intra and intercompany communications are becoming ever more important in daily operations and strategic planning of multi-national business. A reliable global network is in demand to help streamline the distribution of internal information, while enhancing the information exchange process between traders and customers. There have been a significant increase in the usage of telecom services featuring a global environment. It includes facsmile and electronic mail transactions between locations very far apart (with time difference of 8 to 12 hours). Dial-up video conferrencing for example is very attractive and economical at time when intercontinental travel fare is costly.

3.0 Expanding Telecommunications in the Pacific and ASEAN countries

The economic growth of ASEAN countries and the Pacific Ocean Region Countries in the last decade is a fact receiving worldwide recognition. This growth will offer both difficult challenges and interesting oppurtunities in the coming decade. It is an area rich in potential and one where we are

632

likely to see some of the most dramatic developments in telecommunications in the years ahead.

The situation of economic activities between these two regions seem to be, capital and expertise located at Pacific Region whereas raw materials and manufacturing operations in the ASEAN countries. So, it is inevitable that telecommunications facilities need to expand to support the increase in business oppurtunities created in these burgeoning markets.

Optical fiber submarine cable transmission system has emerged as the most economical system for transmitting large amount of digital information in the telecommunications fields. Almost all international submarine system installed after 1989 are optical system. There are several optical fiber systems planned worldwide such as TPC-4, HAW-5, TSL, TAT-9, HJK and Asean Optical Fiber Submarine Cable Network (AOFSCN).

It is well known fact that POR countries have been extensively connected by optical submarine cables and there are few projects in the pipeline. Figure 1 summarizes the existing and planned optical fiber submarine systems in the Pacific. The prospective planning for Trans-Pacific cabling clearly shows that the traffic growth is enormous.

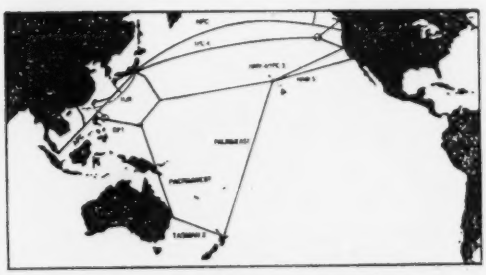

Figure 1: Optical Fiber Submarine Cables in the Pacific

Plan to interconnect all ASEAN countries by submarine optical link was agreed by members in 1988. This led to the acceptance of the Kuantan - Kota Kinabalu (KN - KK) link as part of AOFSCN enabling it to provide transmission capacities for both domestic and international traffic. This link was put into operation since December 1990.

AOFSCN will not only enhance economic activities and political relations between members but the world as a whole. It is an ambitious plan to realise a reliable digital network for the ASEAN region. The whole link will cover a total distance of 4,550 Km with an estimated cost of US $ 320 million. The complete implementation of the plan will end by 1995. Figure 2 shows the AOFSCN configuration.

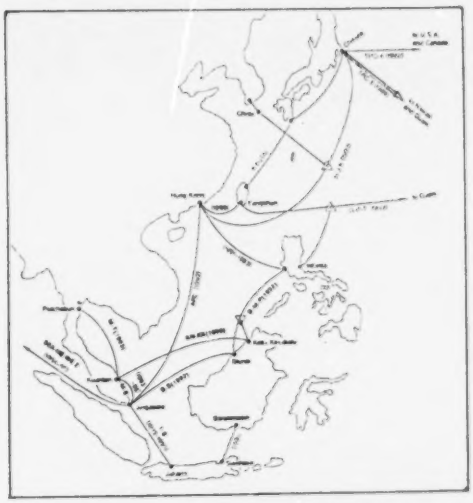

Figure 2: Optical Submarine Cable Network Construction Projects in South East Asia

4.0 AOFSCN

The complete network comprises of six major links as follows:

4.1 Kuantan - Kota Kinabalu Cable System (KN - KK)

This is a 420 Mbps system with two pair of cable. The cost of this 1,500 Km system was M $ 150 million. It has a total capacity of 11,520 voice channel. One pair of the fiber is for domestic traffic and the other is for international traffic.

4.2 Brunei - Malaysia - Philippines Cable System (B - M - P)

This cable will land in Malaysia at Tanjung Aru, near Kota Kinabalu via a branching unit. It is a 1.55 μm system with a total length of 1,600 Km. The capacity of the system is 560 Mbps. It is expected to be ready by 1992. The three landing points will connect via a branching unit which will provide

635

interconnections with other digital cable networks in the Pacific for access HongKong, Japan, the United States, Europe and the Pacific Basin.

4.3 Malaysia - Thailand Cable System (M - T)

This is a 560 Mbps system which is expected to be ready by early 1993. Both Telekom Malaysia and Communication Authority of Thailand are involved in the drafting of the tender. It links Cherating Cable Station at Kuantan and Petchaburi Cable Station, Bangkok covering a total distance of 1,000 Km.

4.4 Malaysia - Singapore Cable System (M - S)

This system will link Malaysia and Singapore. It is expected to be ready by 1995. It is a system with a data rate of 560 Mbps. This link will play a major role in connecting ASEAN to the Pacific since it is a portion of the APC system that will link Malaysia, Singapore, Taiwan and Japan.

4.5 Indonesia - Singapore Cable System (I - S)

This 560 Mbps system will be part of the digital South East Asia - Middle East - Western Europe (SEA - ME - WE 2) cable system. This system will be ready in middle 1994.

4.6 Brunei - Singapore Cable System (B - S)

This system will interconnect Brunei and Singapore. The system is expected to be ready by 1992.

It is clear that AOFSCN is a five years plan beginning from 1990. The complete network is expected to be ready by 1995. We can say positively, that the establishment of this project will be able to sustain traffic growth well into the year 2000. This state-of-the-art infrastructure will undoubtedly bring very rapid financial and socio-economic development in this region.

5.0 The Global Digital Link

Prior to 1989, satellite and fiber optic systems was used for transcontinental communication, each providing about 50% of the circuits. At present, experts in long-distance communication are of the opinion that fiber optic systems account for 50 - 60 per cent of the circuits, as against only 30 - 40 per cent for satellite systems.

The acceptance of fiber optic as a large bandwidth, compact and reliable and future-proof system have started an intensive transoceanic cabling plan worldwide. Figure 3 shows the transoceanic fiber optic lines which are either in service already or due to be put into service in the near future.

Figure 3: Global Digital Ring of Worldwide Telecommunications Network

From Figure 3, it is clear that there are three clusters of link making up the world or global telecommunication network namely, European link, Pacific and American link and Asian link. Every link need to be interconnected with each other to create the desired global communication link. Figure 4 shows how the AOFSCN will be interconnected to the Pacific link. It is expected that by 1995, the global digital link will be realised as shown in Figure 5.

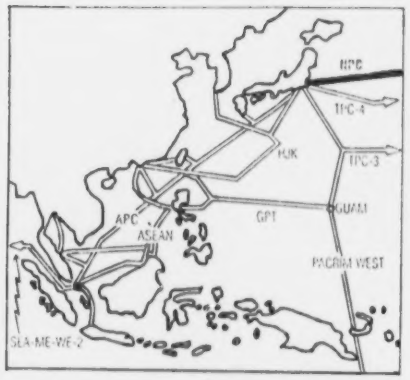

Figure 4: AOFSCN Access to Pacific Region Fiber Optic System

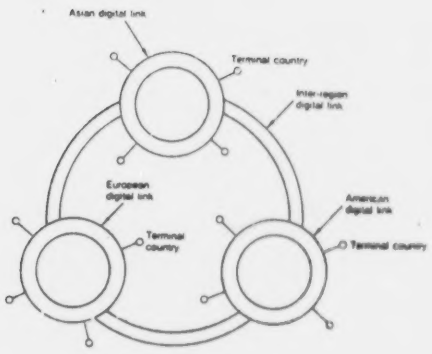

Figure 5: The Future Look of Global Digital Link

6.0 Conclusion

AOFSCN is yet another milestone in realising digital network for the ASEAN region. The linking of this network to the existing and planned POR network is of great political, social and economic importance to the region. It is also an important portion of the global digital communication link. The completion of the whole global link will finally secure a high level of reliability on the world telecommunications network and contribute to strengthening peace and trust between the world nations.

ACKNOWLEDGEMENT

The authors wishes to thank Universiti Teknologi Malaysia for the support given in preparing and presenting this paper. Special thanks to the final year students of electrical engineering for their help in collecting some of the data presented in this paper.

Next Generation Undersea Systems & Technology
Meeting The Needs Of The Global Market

Debra J. Guancione and Larry Blendinger
AT&T Submarine Systems
Morristown, U. S. A.

The next generation of repeatered undersea cable systems are designed for the global market -- offering higher capacities than ever before, increased flexibility and compatibility with emerging international standards and the worldwide intelligent network. These systems, called SL2000 by AT&T, utilize the latest leading-edge technology packaged in a unique design. This design promises to meet customer needs for additional voice capacity while providing increased bandwidth for data, video and other applications.

Historically, the undersea cable system market was driven almost solely by traffic needs. AT&T entered the underwater telephone transmission market in the early 1950's with the first repeatered undersea cable system being installed between the United States and Cuba, providing 24 voice circuits. Following on its heels, the first transatlantic system, named TAT 1, was installed between Newfoundland and Scotland in 1956 carrying approximately 48 voice circuits. A significant growth in the undersea cable system market followed in the 1960's and 1970's to meet the increasing demand for global communications. Technological breakthroughs with semiconductor lasers in the late 1970's then paved the way for faster and more reliable lightwave-based communications and further opened the door for the installation of undersea systems worldwide.

AT&T's lightwave-based systems were initially introduced in the 1980's with 280 Mb/s of transmission capacity, or up to 20,000 voice circuits per fiber pair, meeting virtually any traffic demand of the time. Further advances in lightwave technology have allowed the introduction of the current generation of optical fiber-based systems. These systems, called SL560 by AT&T, provide 560 Mb/s of transmission capacity or up to 40,000 voice circuits per fiber pair. This generation of lightwave systems is comprised of the following major components & technology:

- regenerative repeaters - bit-rate sensitive repeaters which allow the recreation of the transmission signal along the transmission path of the system allowing for longer undersea systems
- terminal transmission equipment - equipment which connects the undersea system to the terrestrial network, or another undersea system, via a 140 Mb/s interface
- power-feed equipment - equipment which provides up to 1.6 amperes of current to the underwater equipment
- optical fiber - provides the optical transmission and signaling paths of the system
- cable - protection for the optical fiber
- branching repeaters - optional repeaters providing signal regeneration, multiple landing site access and switching capability

These components and technology provide SL560 systems with the capability of supporting up to three (3) fiber pairs, thereby maximizing system capacity at 120,000 voice circuits per system. Other attributes of the SL560 technology include a system design life of 25 years, higher performance, and increased reliability over previous technology. The introduction of the new branching repeater provides additional flexibility by allowing access to multiple landing sites and the capability of switching traffic from one destination to another. These attributes ensure that undersea cable customers can meet existing traffic demands with increased reliability and flexibility. The first transatlantic 560 Mb/s system, TAT 9, was installed in 1991.

As undersea systems have evolved, so have customer requirements. Current undersea cable system owners now plan to exceed forecasted traffic demand due to the use of services that require more capacity,

such as, real-time video transmission. These customers are also demanding more stringent performance and reliability, lower costs, compatibility with evolving international standards and the flexibility to meet the world's changing telecommunications needs in shorter timeframes. Tomorrows undersea systems must be able to meet these needs.

The next generation of repeatered undersea cable systems are designed to meet these customer's expectations. These systems are designed to offer up to 5.0 Gigabits (Gb/s) of transmission capacity or up to 160,000 voice circuits per fiber pair. This kind of increased capacity means overall reduced unit costs to customers. These systems also provide the flexibility of supporting 2.5 Gb/s and/or 622 Mb/s of transmission capacity meeting the needs of those customers with lower initial traffic requirements. These customers may, if the maximum transmission rate they require (for example, 5.0 Gb/s) is planned and installed, change the transmission rate of the system (for example, from 2.5 Gb/s to 5.0 Gb/s) by changing the terminal equipment only at any time during the system life.

Additionally, up to four (4) fiber pairs will be supported providing up to 640,000 voice circuits per system. SL2000 systems will also operate over longer distances than previous systems -- over lengths of up to 9,000 kilometers, and offer a branching unit should customers require multiple landing sites. These systems will meet or exceed CCITT (Consultative Committee for International Telephone and Telegraph) transmission performance requirements and will have higher reliability.

To accomplish these capabilities, this future generation of systems is based on a unique packaging of components and advanced technology -- optically amplified bit-rate insensitive repeaters, bit-rate sensitive terminal equipment, dispersion-shifted fiber, and cable. These components are briefly described as follows.

The bit-rate insensitive repeaters are being developed with a minimum of active components and are based on Erbium Doped Fiber Amplifiers (EDFAs) used in an optical amplifier unit. This optical amplifier unit is housed within the repeater casing. Erbium doped fiber is a special type of optical fiber doped with the rare earth element, erbium. When pumped with light, via a pump laser, in a specific metric range, the erbium fiber provides amplification for an optical signal. The pump laser, which is a semiconductor laser diode, produces the light providing the erbium fiber with the necessary energy for the erbium doped fiber to act as an optical amplifier. Since these optically-amplified repeaters have been designed with far fewer active components than regenerative repeaters, the likelihood and number of component malfunctions is reduced, thus, overall reliability of these systems will be increased.

As described earlier, the terminal transmission equipment of previous digital systems provides the interface at the 140 Mb/s (the CEPT-4 CCITT) standard interface rate between the local terrestrial network and the undersea cable system. To ensure compatibility with future international standards, the next generation of undersea system's terminal equipment will also support the 155 Mb/s (STM-1 CCITT Synchronous Digital Hierarchy [SDH]) standard interface. The number of such interfaces is dependent on the maximum optical line rate selected by the customer. That is, the maximum optical line rates are 622 Mb/s, 2.5 Gb/s, or 5.0 Gb/s. Thus, for example, a 622 Mb/s maximum line rate can support transmission capacities of either four (4) CEPT 4 (140 Mb/s) or four (4) STM-1 (155 Mb/s) signals per fiber pair. In addition, a mix of these two rates can be accommodated as long as the combined capacity does not exceed the maximum line rate.

Several types of previously proven AT&T SL cable including Lightweight, Armored and Special Applications cable will be used in these new systems depending on the ocean environment. These systems will also utilize Dispersion Shifted Fiber which is a special type of optical fiber. This type of fiber is required to mitigate the effects of fiber dispersion.

This combination of components and state-of-the-art technology will meet customers high volume traffic needs for voice, data, teleconferencing, television and other services at lower cost. The higher reliability is critical to those information-based companies requiring fast and accurate information transfer worldwide. Taking us through the 1990's and beyond, SL2000 systems are expected to be generally available in early 1995. And, as with any new technology, current experiments are showing promise for increased capacity, such as 10 Gb/s, and may provide for capabilities yet unknown and for services not yet imagined -- meeting the needs of the global market.

PACIFIC SCARAB ONE
DEEP WATER ACQUISITION, BURIAL and RETRIEVAL

by

Robert T. Bannon
Senior Engineer
AT&T / Transpacific Communications, Inc.
340 Mt. Kemble Avenue
Morristown, New Jersey 07960, USA

Abstract

The Pacific Submersible Craft Assisting in Repair and Burial, PACIFIC SCARAB ONE ™ (PS-1) is a fifth generation Remotely Operated Vehicle (ROV) designed specifically for underwater cable maintenance and repair operations. PS-1 established a new record for ROV's engaged in cable maintenance by performing full jetting and burial functions at 2684 meters. In addition, PS-1 was designed for launch and recovery in adverse sea conditions, up through Sea State 5. PS-1 incorporates the newest advanced work packages and specialized tools required to perform a wide variety of undersea tasks, such as cable sensing, object acoustic signature recognition and acquisition. PACIFIC SCARAB 1 is used for inspection survey, cable acquisition, maintenance and restoration of international communications in the Pacific and Indian Oceans and other select recovery projects. This paper discusses the ROV's design, functional capabilities and its performance criteria.

Introduction

The PACIFIC SCARAB ONE system represents the latest design specification for ROV's from Transpacific Communications, Inc. (a subsidiary of AT&T) and Teleglobe Marine, Inc. (a subsidiary of Teleglobe Canada). PS-1 is based in Astoria, Oregon and will provide cable repair and burial assistance for the North American Zone of the Pacific and Indian Oceans Cable Maintenance Agreement (PIOCMA). It will also be available for commercial applications and specialized recovery projects.

PACIFIC SCARAB ONE is the fifth in a series of submersible ROV's dedicated to cable work. Although PACIFIC SCARAB ONE is very different in design and vintage from SCARAB I, II, and III, they all provide the users with vehicles specially designed for cable acquisition and recovery. PACIFIC SCARAB ONE shares the basic design parameters of SCARAB IV, the major differences being their depth ratings and the speed and vintages of their computer hardware, software and electronics.

Pacific SCARAB ONE and SCARAB IV are both operated by TPCI. SCARAB III and IV are on stand-by in Vigo, Spain and Baltimore, Maryland respectively and they are dedicated to providing cable maintenance support to the Atlantic Cable Maintenance Agreement (ACMA). These vehicles are owned and operated by a five member International Consortium. SCARAB II is owned totally by AT&T / TPCI and is operated out of the Baltimore depot. It is available for a variety of uses, including ACMA assignments and commercial applications such as the recovery of the flight recorder for the Air India disaster.

The PACIFIC SCARAB ONE contract was awarded to OCEANEERING TECHNLOGIES, formerly Ocean Systems Engineering, in October 1990. After completing sea trials and final acceptance tests in Alameda Canyon in the Gulf of Mexico, PACIFIC SCARAB ONE was placed in Ready For Service status on June 1, 1991, and was officicially accepted as of July 15, 1991.

By exercising the multiple vehicle option of the SCARAB IV contract, and by utilizing its basic design, a major time savings associated with design was realized.

OCEANEERING TECHNLOGIES incorporated many of the SCARAB IV modifications implemented during Hawaii 4 Burial Project into the design criteria of Pacific SCARAB ONE, along with many new technology innovations. The major differences between the two vehicles are PS-1 incorporated addition operating depth requirements, improved system efficiency and additional power requirements. In addition, PS-1 design allows for the mounting of spe-

BEST COPY AVAILABLE

cialized tool handling and delivery systems that were not included in previous vehicles.

Although the Pacific SCARAB ONE bid requirements included a burial depth of 0.6 meters at 300 meters per hour similar to the functional requirements which was delivered in SCARAB IV, experience has led to improvements in the jetting skid design takes the current state-of-the-art far beyond previous capabilities. These will be discussed in details in the Jetting and Excavation Skid portion of this paper.

PACIFIC SCARAB ONE 's specification represents the continued development and refinement directions for AT&T / TPCI's vehicles which demand the free flying maneuverability to negotiate wide ravines and canyons and cable suspensions.

PACIFIC SCARAB ONE Performance Design Criteria

The HAW-5 and TPC-4 cables that are planned for installation in 1992 and 1993 represent the latest evolution in fiber optic communications. With the advent of this new SL fiber optic cable used for international communications, service interruptions represent a major loss of revenue to a communications company.

Service interruptions on undersea cables are minimized as a result of burying cables in areas of high fishing activities, installation of armored cable in unburied sections, and cable protection education of sea bottom users. However, they do occur through trawling accidents, abrasive wear and other natural disasters such as undersea earthquakes and sea bottom slides. As a result of rerouting and satellite restoration capabilities, we are able to minimize outage effects. However, under the terms and conditions of the various cable maintenance agreements, we must retrieve and repair damaged cables in a timely and economical manner. Therefore, to achieve this goal, we must frequently undertake the acquisition, retrieval, repair and burial of a cable in less than ideal conditions. To enable us to meet these service demands, we incorporated stringent operating specifications into the design criteria for PACIFIC SCARAB ONE.

In an attempt to limit the time that PACIFIC SCARAB ONE would spend Waiting-On-Weather and to ensure it could operate under severe weather conditions, an extensive operating criteria was included in the design specification. The performance specification included items such as operational depth requirements, surface and bottom currents requirements, vehicle launch and recovery criteria and jetting and excavation requirements for a variety of soil compositions. As stated earlier, many of the design criteria evolved from operational experience gained while burying the HAW-4 cable off Pt. Arena, California in May and June of 1990 with SCARAB IV.

Since the PS-1 operating criteria and the design specification far exceeded those associated with previous vehicles, there were some increased costs. In certain areas, however, these were offset by using the SCARAB IV design and specification as a cost foundation for our new vehicle. For example, the extended depth capabilities required additional engineering and material costs associated with the umbilical and foam pack, however, the design time savings and packaging similarities of the two vehicles resulted in an overall savings benefit.

PACIFIC SCARAB ONE System Description

Because of the wide variety of work that has been proposed for PACIFIC SCARAB ONE, like its predecessors, PS-1 was designed with a modularized, self-contained system concept in mind. This allows for the rapid mobilization and demobilization required for installation on a wide variety of ships that may be assigned as a work platform in the Pacific Northwest. This varied deployment of PACIFIC SCARAB ONE on a vessel of opportunity must be accomplished within forty-eight hours. Therefore, an integrated subsystems approach is essential to the deployment of the vehicle configured for specialized tasks. The major subsystems of PACIFIC SCARAB ONE are:

- Remote Operated Vehicle and Seven Function Manipulators
- Jetting and Excavation Skid
- Underwater Tools
- Umbilical
- Umbilical Winch and Hydraulic Power Unit
- Launch and Recovery System
- Control and Observation Subsystem
- Generator Set

Remote Operated Vehicle and Seven Function Manipulator Subsystem

The PACIFIC SCARAB ONE ROV is an electro-hydraulically powered system developing 150 horsepower from its two 75 hp Franklin motors. The navigation suite, manipulator arms and the specially designed tool packages are all microprocessor controlled. Tightly packaged, with dimensions of 4m x 2m x 2.2m, and a weight of approximately 5.3 tons, the ROV can achieve forward flight at a speed greater than 4 knots. Most importantly, PACIFIC

SCARAB ONE has been proven to perform at 2500 meters and has been tested at 3000 meters to ensure a safety margin.

In spite of its size and weight, PACIFIC SCARAB ONE is designed to be positively buoyant and float proud in the water. The additional depth requirement, beyond that of SCARAB IV, resulted in additional vehicle weight due to greater crush resistance of various electronic canisters, the addition of the Enhanced Bottom Sonar System (EBSS), and additional umbilical length. Therefore, to meet the positive bouyance requirement redesign of the syntatic foam block was required.

The vehicle is equipped with two fore/aft thrusters, two lateral thrusters and four vertical thrusters. As a result of this propulsion configuration, PACIFIC SCARAB ONE has a higher degree of maneuverability than its predecessors and many smaller, lighter ROV's. Microprocessor controlled pitch and roll sensors and both long and short ranged altimeters, coupled with advanced flight control algorithms provide automatic control of heading, depth, altitude, and pitch and roll. The incorporation of this state-of-the-art automatic flight control and high quality computer graphic displays significantly reduces pilot fatigue and stress. Thus, the pilot can concentrate on the main mission objectives.

As a result of lessons learned from SCARAB IV, the tightly designed packaging and the strategic location of equipment reduce vehicle noise. PACIFIC SCARAB ONE is quieter in the water than any vehicle its size, including the other HYDRA based vehicles to date. It is even quieter than ROV's and RCV's (Remote Controlled Vehicles) that are much smaller and lighter, and its acoustic signature approaches RCV's using electric motors for propulsion. In addition, because PACIFIC SCARAB ONE uses highly sensitive magnetometers for object and fault location, this reduction in acoustic and magnetic signatures is essential for efficient cable tracking and object signature identification.

PACIFIC SCARAB ONE is equipped with two specially designed seven- function manipulators that can be configured for mounting either on the main vehicle or on the jetting skid, depending on the task at hand. These manipulators were designed with unique wrists capable of outputting 95 Nm of torque and each has the capability of lifting 150 kilograms at their fully extended reach of 1.5 meters. The mounting positions for the manipulators allows a wider degree of movement over that of SCARAB IV. A newly designed hydraulic tool delivery system, which presents the tools to the manipulators, adds increased flexibility. Because of its superiority over previous packages, it will be retrofitted onto SCARAB IV.

To allow the pilot and bridge supervisor to scan the vehicle flight path or to observe jetting or functions being performed by the manipulators, PACIFIC SCARAB ONE is equipped with five high definition video cameras, one of which is color. These cameras are equipped with hydraulic pan and tilt to provide the widest, and most clear field of viewing.

Jetting and Excavation Skid

Because the jetting and excavation skid is designed to bolt to the bottom of the PACIFIC SCARAB ONE ROV subsystem, it has been designed to provide neutral buoyancy. This is required to ensure the overall positive buoyancy of the ROV system. The skid has the same footprint as the ROV, 4 m x 2 m, and has a design height of 1.1 meters, including the floatation foam that mounts between the ROV and the skid. Since jetting and excavation are bottom activities, the skid is equipped with two parallel skis, thus allowing forward and aft motion on a wide variety of ocean bottom terrain.

To allow the burial or excavation of either a cable or an object for recovery, the skid subsystem is equipped with three pair of high volume, low pressure nozzles, three pair of low volume high pressure nozzles, and two excavation nozzles. Each pair of nozzles can be deployed independently by the operator to achieve the desired burial depths in a soil composition varying from loose sand to crusted bottom to highly elastic clay. As a result of burial operations on the HAW-4 cable, the original design was modified to provide addition protection for the cable if the jetting pressure forces the cable off the bottom, a protection block prevents it from jamming between the nozzles and the frame. Another design change now incorporates the same nozzle on the entire skid assembly, eliminating multiple sets of spare nozzles.

The excavation tools can be configured for operation at either the fore or aft of the vehicle. In areas that require large volumes of soil to be ejected, the forward excavation tools can be supplemented by a high volume venturi lift which is held in one of the seven function manipulators. This tool package was used effectively on the SCARAB IV HAW-4 Burial. Using the venturi vacuum we were able to evacuate significantly large pits required to bury loops and bows in cables. In addition, a quick connect firehose can be attached to one of the vehicle pumps if it is desirable to use a high pressure wash to blow away debris

from repeaters or to reposition soil under a minor suspension.

By the use of computer graphics and pull-down menus the pilot can select the proper nozzle deployment configuration based on soil type and determine the proper depth for jetting. The graphic display on the control console also provides visual data on the burial process. In addition, the camera mounted beneath the skid can be focus on the jetting and subsequent trench.

Underwater Tools

As previously discussed in the ROV subsystem description, PACIFIC SCARAB ONE is equipped with two seven function manipulators, which can be mounted on either the ROV or the jetting skid, depending on the task to be done. The manipulators can be equipped with specially designed tools for cable gripping and cutting, point burial or excavation and recovery scoops and baskets.

The two hydraulically activated cable grippers, which are part of the tool suite, can pick up cables as small as 2.58 cm and securely hold the cable in their jaws until the cable can be brought onboard ship for repair and splicing. Once a gripper is hydraulically locked on the cable, it is dropped from the manipulator, and a recovery line attached to the gripper is used to haul the cable from the ocean bottom to the ship. Once the crushed end of the cable is cut from the recovered cable, the gripper is hydraulically opened and can be reused. The cable end is "stoppered" to allow recovery.

The cable cutting tool is an intensified hydraulical powered system, and the cylinder actuated anvil is capable of cutting through 100 mm double armored cable.

Because of the dulling effect and stress caused by cutting armored cable, both the anvil blades and the anvil itself are easily replaced.

The point burial tool is a high volume, low pressure jetting nozzle that is deployed via the manipulator to bury or excavate in areas that are not easily accessible by the vehicle. As mentioned earlier, a high volume venturi vacuum lift can also be held by a manipulator for clearing larger areas.

Umbilical

PACIFIC SCARAB ONE uses optic fibers to communicate from the control console microprocessor to the microprocessors onboard the ROV. This duplex communication is handled via seven multimode optic fibers and three single mode fibers. One of these fibers is dedicated to serve as an EBSS calibrated link.

Power is delivered from the generator set to the vehicle over copper conductors. Both the fibers and copper conductors are encased in a contrahelically wound double armored umbilical. The engineered break strength of the umbilical is in excess of 30 tons, therefore it can be used for emergency recovery of the vehicle. Floatation devices are directly attached to the umbilical to keep it from lying on the bottom and to keep it suspended off the seabed out of the vehicle's path. The direct application of the football floats to the umbilical was found to be the desired methodology when SCARAB IV's umbilical management was compared to SCARAB III which attaches the floats to the umbilical with mountaineer knots. The use of flotation devices that encapsulate the cable prevents stress points that allow the heavy umbilical to kink. PACIFIC SCARAB ONE 's umbilical attaches direct to the winch and optical interface units without the use of a Tether Management System (TMS), therefore it can achieve a higher degree of maneuverability than a tophat system, especially when liveboating in shallow water.

Umbilical Winch and Hydraulic Power Unit

Because we mobilize PACIFIC SCARAB ONE on various ships that are available in the Pacific for cable maintenance and repair, deck space is often at a premium. To minimize deck space allocated for the umbilical winch and hydraulic power unit, these units have been configured vertically and occupy a single footprint. Because speed in mobilization is also critical, the winch frame incorporates ISO corners for rapid tiedown.

The winch is a drum type unit with a right angle, electronically controlled levelwind. The levelwind, smoothes the layers of umbilical as it is retrieved, thus eliminating cable pile-up.

The primary purpose of the winch is to retrieve the umbilical at a uniform rate and tension from deep water. However, as stated earlier, the umbilical is rated in excess of 30 ton lift capacity, therefore, the winch has also been sized to retrieve PACIFIC SCARAB ONE from the bottom in cases of "dead-sub" recovery. The winch subsystem is equipped with total redundancy, therefore either of the winch drive motors has the capability of lifting PACIFIC SCARAB ONE.

The hydraulic power unit (HPU) and the levelwind are mounted above the winch. The HPU supplies power to both the umbil-

ical winch and the constant tension winch, which is used for normal vehicle recovery. In an attempt to streamline component weights, hose size and pressure, a primary hydraulic pressure of 4/4 bars has been chosen as part of the engineering design criteria.

The design of the electrical system results in a configuration that prevents or minimizes component damage as a result of high voltage failure. The design calls for two sets of electrical slip rings. The high voltage slip rings are mounted on one end of the winch shaft, while the signal and low voltage slip rings are mounted on the other end of the winch shaft.

Launch and Recovery System

The PACIFIC SCARAB ONE launch and recovery system is comprised of an articulated crane, constant tension winch, swing frame and an overboarding sheave. The articulated or knuckle crane has a reach of eleven meters and designed to reach over the side of most ships to nearly the waterline. This capability allows PACIFIC SCARAB 1 to be lowered a very short distance into the sea, thus lessening the air-to-water-interface impact. It also increases our ability to launch in adverse seas and high wind conditions.

The constant tension winch is mounted on the first knuckle of the crane and is responsible for keeping a constant tension on the recovery line during launch and recovery sequences and during the vehicle power-up sequence and thruster testing. During these sequences that demand high recovery line control, the constant tension winch has the capability of feeding in and paying out up to 90 meters of SPECTRA 12 line per minute.

The swing frame is equipped with a disk brake assembly to dampen swing motion of the vehicle while PACIFIC SCARAB ONE is in the air during launch and recovery. In addition, the swing frame is equipped with air shock absorbers to lessen the impact between the swing frame and the ROV's floatation foam during the latching procedure, prior to vehicle lift. The male or positive latching mechanism which is terminated to the end of the SPECTRA 12 line is considered part of the swing frame subsystem. Because of the severe conditions experienced on the West Coast and the additional weight associated with PS-1, the latching mechanism has been designed to reduce stress on the vehicle attach point.

Crane motion - extend, lift, knuckle-in and knuckle-out - as well as the operation of the constant tension winch and latch mechanism is controlled from the crane operator position mounted on the base of the crane pedestal.

Control and Observation Subsystem

The PACIFIC SCARAB ONE control and observation subsystem is divided into four primary stations: the control van, supervisor's center, portable bridge and belly-pack controls for the ROV and umbilical winch, and the remote observation center.

The control van is effectively the brain of the PACIFIC SCARAB ONE system because it is here that the AT&T 6486 Star Server S System and the Hewlett-Packard computers that control the all electronic and hydraulic functions are located. These computers are responsible via optic fiber links for communication with the microprocessors that control the ROV's electrohydraulic functions and the umbilical winch.

In addition to video displays that are linked to each of the ROV's five cameras, there are multiple computer graphic displays to aid the pilot and the tools operator in remotely controlling and manipulating a complex integrated system.

It should once again be pointed out that the use of multiple cameras allow the pilot and the bridge supervisor to have better points of observation for the descent/assent mode or while jetting. In addition to the twin Sony monitors mounted in both the pilot's and the tools operator's consoles, each has a 20-inch Sony high definition monitor that can be used to display images from any of the cameras. The consoles also contain graphic displays that incorporate graphic data such as depth, attitude, pitch, nozzle deployment, thruster activity oil compensation pressure, acoustic signatures of cables and other objects and cable tracking data. There is a second graphic display that tracks position of the vehicle in relation to the ship. This acoustic positioning system also displays other proprietary information important in our cable acquisition and retrieval efforts.

This system represents state-of-the-art computer graphics to control all functions, utilizing a track ball to activate selections from pull down menus. Banks of switches and gauges have been eliminated from the control center in favor of the computer graphic displays and menus. Operator diagnostics and alarms are also graphically displayed. System setup, calibration, troubleshooting and operations are all controlled from the computer graphics console in the control van.

The supervisor's center is located on the ship's bridge during acquisition and recovery missions. The displays in the supervisory console are duplicates of many already located in the control van. However, the lack of ROV command control in the Supervisory Center is the significant difference, even though both centers display identical pull down menus and diagnostic graphics. The supervisor's center includes two Sony display monitors that can receive video input from any of the PACIFIC SCARAB ONE cameras, and two acoustic positioning system monitors, one of which is positioned for viewing by the ship's quartermaster while at the helm, and a pen plotter for output plots of navigational data.

PACIFIC SCARAB ONE's navigational system represents a complex integration of navigational data inputs from the cable tracking magnetometer system, the acoustic positioning system and the ship's navigation input. The ship's navigational input is dependent on the ship on which PACIFIC SCARAB ONE is mobilized, and may be manually calculated, based on Loran SEA output, or be obtained from either the Global Positioning System (GPS) or the Dynamic Positioning System (DPS). All inputs are integrated in real time to give an extremely accurate bottom positioning for the vehicle. During the Hawaii 4 Burial Project, shore mounted trisponders were also used in conjunction with the DPS. This allowed the ship to be located very close to the plotted cable location. This ensured that the cable acquisition effort was reduced to a minimum time.

The PACIFIC SCARAB ONE portable bridge pack and the belly-pack controls for the ROV and the umbilical winch provide remote controls for both subsystems. These units can be located on either bridge wing, or any other high point on a ship that will provide the best view of the ROV on the water surface for the launch and recovery sequences. Locations other than the control van or the the supervisor's center provide the advantage of watching the position of the ROV in relation to the ship's hull and for for observing actual air-sea interface. The belly-pack, like the bridge pack, also includes a communication link to the control van, the supervisor's center, the remote observation center and the crane operator's position.

The remote observation center, like the control van and supervisor's center contain video monitors, a video recorder and a video typewriter for annotation. This center is for non- critical personnel - those not involved in the system control and operation - who desire to observe and record a project. Personnel at this location do not have the option of selecting the video input displayed on their own; the camera input desired must be requested from the operators in the control van who will switch in the desired video input.

Generator Sets

PACIFIC SCARAB ONE 's power requirement is 2300 VAC, 3-phase at 60 Hertz. Because of this high power demand, PACIFIC SCARAB ONE incorporates two diesel generator sets in its design to eliminate dependency on ship's power. Each of these generators are capable of assuming the full power requirement for PS-1, thus providing the redundancy required for emergency situations. Another reason for supplying generators as part of the PACIFIC SCARAB ONE system is that many of the ships available are of foreign registry, and their power plants are 50 Hertz. In addition, their plants may not be sized to provide the demand on isolated circuits without major plant modification.

Conclusion

PACIFIC SCARAB ONE represents the 1991 view for the current state- of-the-art ROV design, computer graphic flight control and diagnostics as well as seven function manipulator robotics. In addition, the same claim can be made for the cable location and tracking system.

This ROV is equipped with an AT&T Enhanced Bottom Sonar System (EBSS) which is an acoustic signature identification system that can switch between parametric and linear sonar. EBSS has a bottom penetration of 3 meters to allow for cable or object location and bottom profiling. EBSS is designed to operate at depths up to 6000 meters. In September 1991, 26 uncontested patent claims were granted to AT&T for EBSS. Features and capabilities of EBSS were presented at the OCEANS'91 Conference also held in Honolulu. EBSS is an AT&T Standard Product from the International Submarine Maintenance organization.

AT&T / TPCI and TMS are dedicated to protection and maintenance of Pacific Undersea Cable Systems. And, PACIFIC SCARAB ONE and its Atlantic predessors, will continue to evolve with the application of new and leading edge technology. AT&T International Communications Services is dedicated to providing quality communications service worldwide.

This same dedication and skill level is applicable to any commercial ventures for PACIFIC SCARAB ONE. TPCI will operate this ROV with only highly experienced personnel to guarantee mission success.

AT&T Submarine Systems, Inc.
Non-Repeatered Product Overview

Barbara Haldeman
AT&T Submarine Systems, Inc.
Morristown, U. S. A.

AT&T Submarine Systems Inc. (SSI) Non-Repeatered Product combine Terrestrial Terminals with Submarine Lightwave Cable Technology to provide a full range of Voice, Video and Audio Teleconferencing Data and Wideband Services.

As the demand for telecommunications facilities has increased world wide, AT&T Submarine Systems, Inc. is becoming recognized as the Market Leader in the supply of Turnkey Fiber-Optic Submarine Cable Systems. Leading the International field in the system planning, engineering, installation, maintenance and overall end to end support for undersea submarine cable systems. AT&T's milestones in lightwave technology began with the successful installation of the Optican-1 system, the world's first commercial repeatered deep sea lightwave system, installed between Tenerife and Gran Canaria in the Canary Islands in September, 1985. The completion of the TAT-9 system in October 1991 was AT&T's first system using the SL560 mbps technology. It spans 4,652 Kilometers and consists of 42 Repeaters. Undersea cable systems that require the use regenerative technology (repeaters) has steadily increased. This is also true for systems that do not require repeaters, the Non-Repeatered Submarine Cable System.

Non-repeatered systems are steadily becoming the preferred telecommunications solutions to connect two terrestrial locations separated by a body of water without the need for regeneration or amplification of the optical signal. The capacity or bandwidth requirements are readily upgradeable in a non-repeatered system since there is no undersea plant (repeaters) involved. Upgrading of the terrestrial terminals will provide additional capacity to the same installed cable as the traffic demand increases. The primary application for non-repeatered systems exists in the National market typically defined as extensions of existing terrestrial networks, versus the international market where repeatered systems typically are required. These applications:

1. Mainland to island links
2. Island to island links
3. Coastal loops
4. Crossing large bays or rivers
5. Mainland to offshore installations (e.g., oil platforms)

AT&T's first non-repeatered system known as TAIPN 1 was installed in August of 1988. It connected Tainan and Pengh-Hu in the Taiwan Strait and consisted of 104 km of cable and terrestrial terminals with a capacity of 417 mbs. In 1991 AT&T was awarded the Qualo, Chemlu and Cameron Lakes system consisting of 167 kms of cable as well as the Taino-Caribe system consisting of 186 kms of cable and terminals with a capacity of 565 mbs. To meet customer's requirements for increased span lengths in the non-repeatered marketplace, AT&T Micro Electronics has developed, with the expertise of Bell Labs, a Fiber Power Amplifier Booster Module (FABM) using Erbium Doped Fiber Amplifier technology. When combined with terrestrial terminals, longer span lengths can be achieved. In addition the FABM can also be used to overcome dispersion problems should they exist. The FABM is designed as an optical interface for a 622 mb/s or 659 mb/s lightwave terminal. The FABM extends the transmission range of North American/Sonet and CEPT/SDH terminals to the maximum non-repeatered span lengths possible, while preserving terminal features and functionality.

AT&T-SSI has also recognized the need for lighter weight, easier to install undersea cable. To this end, AT&T-Bell Labs has designed a new cable type specifically for use in non-repeatered undersea cable systems. This new design, much like our SL cable design, used in repeatered systems, has the same 25 year life expectancy and is comparable in strength and robustness as our traditional SL cable. The cable consists of an SL Unified Fiber Structure (UFS) containing up to 12 optical fibers, a

strand package with 16 high strength steel wires, a copper sheath and a plastic jacket. The SL polyurethane waterblocking compound used, protects the cable from water ingress. This new cable design, available unarmored, single or double armored, can be buried and recovered from the ocean bottom should a repair be required.

The key technical requirement for Non-Repeatered Systems is increased span length while maintaining systems' margins. With the combination of the Fiber Amplifier Booster Module, developed by AT&T Micro Electronics, terminals from AT&T Network Systems, fiber options such as Dual Coat Germanium Doped, Silica Core and Dispersion Shifted Fiber and AT&T's new cable design, AT&T SSI is here to meet and hopefully exceed your expectations. It has been our experience that each customer is unique in its requirements for a non-repeatered undersea cable system.

Our years of experience in planning systems with our customer provides high reliability maintenance, installation, training, on time delivery, as well as our expertise in marine operations, positions AT&T Submarine Systems as a value added end to end supplier of both repeatered and non-repeatered undersea cable systems.

THE ALOHA CABLE: A NEW SELF-RESTORING, HIGH CAPACITY CABLE WITH SONET

DENNIS W. ELLIOTT,

TRANSNATIONAL TELECOM, WASHINGTON, D.C., U.S.A. &

GEOFFREY THORNTON,

STC SUBMARINE SYSTEMS, GREENWICH, U.K.

1. ABSTRACT.

There is a substantial need to increase the resilience of high capacity undersea cables to man-made disruption. In addition, there is a critical need to increase the capacity of digital transmission facilities between Hawaii and the U.S. mainland. The Aloha cable meets each of these needs with a new self-restoring design and by employing STC Submarine Systems' evolutionary 2.5 Gbit/s SONET-standard cable design. The result will be the world's largest, most reliable undersea fiber optic cable by the end of 1993!

2. INTRODUCTION & BACKGROUND.

Although advances in undersea fiber cable technology appear to be heading in a fairly well defined, straightforward path, in fact progress is much more complex. As we devise larger and larger capacity systems, the changes in the process by which we operate these systems is analogous to the change in passenger handling arising out of the introduction of very large jet aircraft. Loading three or four hundred people and their baggage on one vehicle in reasonable speed and comfort requires a different approach to loading fifty to a hundred people on a plane. Similar changes can be seen in the new Aloha Cable system.

Transnational Telecom (TTL) of Washington, D.C. is constructing the Aloha submarine fiber optic cable between Oahu, Hawaii and Oregon. STC Submarine Systems (STC), a division of Northern Telecom, is TTL's turn-key contractor for the system. The Aloha Cable will employ STC's NL 16 2.5 Gbit/s SONET undersea cable technology capable of over 32,000 simultaneous uncompressed telephone calls. When operational in late 1993, the Aloha Cable will be the highest capacity submarine cable in the world and will represent two firsts: employment of SONET technology and a new self-restoring design. As a system, its technical interest is therefore not confined to its high bandwidth but also in other features that its configuration offers.

3. ALOHA: KEY FEATURES.

Four key features of the Aloha Cable system are:

1) Self-restoration.

2) High bandwidth, 2.5 Gbit/s capacity.

3) SONET standard transmission.

4) Standard terminal equipment.

These key features are described below:

3.1 Self Restoration.

Fundamental to any network planning is the need to be able to restore a link in the event that use of the system is denied to the network operator. When a cable system is unavailable, the most common method of restoration has been via satellite. However, developments in recent years have made this an increasingly difficult option. In the first place, an increasing number of users prefer cable for their data/voice transmission path and this has generated demand for cable on cable restorations. Secondly, the rapid increase in the bandwidth of cable systems is making it impractical to restore by satellite because the bandwidth necessary is simply not economically available.

656

In network planning terms the solution is increasingly seen as the use of a ring configuration for a submarine cable system. A ring has the elegant simplicity of always offering two routes between any two points on the ring and therefore a cable break can be restored by the simple process of "going the other way around". This concept has recently been incorporated into the planning of new cable systems in both the Pacific and the Atlantic. However, this is for the second half of the decade and since it involves, in effect, two completely separate cable systems, it is an expensive solution to the problem. The Aloha cable system has been designed to provide the restoration capability of a complete ring next year without the high associated costs.

An analysis of the causes of cable failure indicates that there are two types which have to be guarded against. One is electrical failure, which is uniformly likely to happen anywhere in the system. The other is a cable strike severing or damaging the cable and making the whole cable unusable. This is usually the result of fishing activity or the dragging of an anchor. This latter type of failure is almost wholly confined to the shallow water sections of the cable route.

a) Electrical Failure.

All submarine fiber optic systems of any length have built-in protection against electronic failure. This in its simplest form is provided by redundancy of the components most likely to suffer failures. However, greater security has been provided in most transoceanic systems by means of a spare line.

The system being employed in Aloha allows the traffic to be switched from one fiber pair to the other at a repeater. The system would, therefore, be capable of coping with a considerable number of electrical failures (in the unlikely event that this was necessary). It is worth noting that very few systems of the length of Aloha or longer have had the confidence not to employ a spare line. One of the consequences of the high rate of technology change in the optical submarine cable business is that one generation of technology rapidly follows another. Although Aloha will go into the water next year with a transmission line rate of 2.5 Gbit/s, there is at this stage less than six months of underwater experience with any commercial system using the 1.5 micron lasers designed into all submarine fiber systems operating at line rates of 560 Mbit/s and above.

b) Physical Failure.

The risk of physical damage to the cable is generally confined to the shore ends at water depths of up to 1500 meters. The Aloha Cable system overcomes this problem by offering a duplicated shore end construction at each end with the two "branches" linked on land and remotely switched at a branching unit in relatively deep water (about 1500 meters depth). Thus there is always a standby cable available in those portions of the cable route where there is a risk of mechanical damage. The two shore ends are linked together terrestrially and thus it can be seen from Figure 1 that the Aloha Cable system is in effect a ring system in which both deep water parts of the route are contained within one cable casing. The ring itself is completed by interconnecting the twin landing points via the Aloha terminal office or point of presense (POP) as part of the ring.

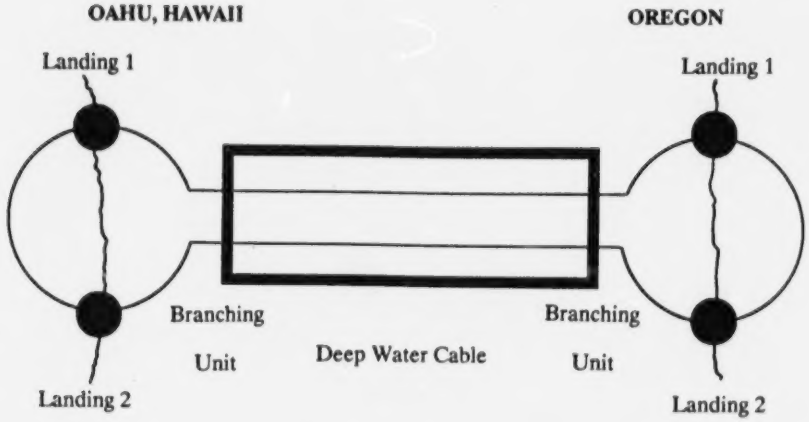
It could be suggested that there is still a higher risk as a result of the single physical connection between the two branching units. However, it must be stressed that: firstly, physical damage to the cable in deepwater is extremely rare and secondly, that the probability of an event which would take out both shore ends is, if anything, greater than the probability of the deep water break. Extending this argument, the risk of a ring system being unable to restore itself is extremely small and the exact configuration of the deep water portion of the ring has little impact on the probability of an outage.

c) Repair Outage.

It has been suggested that in the event of a cable break it would be necessary to de-power the whole system before repairing the damaged leg thus reducing the effectiveness of the duplicated landings. The latest developments in marine repair techniques have overcome this problem. Late last year a fault occurred in the French leg of TAT-8. This fault was repaired without the necessity of taking the US-UK leg out of service. This is in contrast to the earlier repairs on the French leg in 1988 when the system had been de-powered following the old maxim "put not your trust in switches".

To avoid the hazard to the operators of the cableship occasioned by attempting to repair a damaged spur, it should be noted that the voltage at the branching unit can be reduced to zero. With Aloha it is possible to adjust the power feed at each end of the cable using positive and negative voltages so that the voltage is zero at the branching unit connected to the leg with the outage. By grounding the shore end of that leg, then, both ends of that leg, and thus the whole of the leg is grounded during a repair. This is reinforced by the power relay being switched away from the line current. As a final protection, it is now possible to grapple for a cable and provide a satisfactory ground

Figure 1. ALOHA SELF-RESTORATION.



before the cable leaves the water. Thus, the cable is brought aboard the repair vessel already grounded and procedures have been established to attach a more permanent grounding to the system before work is started upon it.

3.2 Gigabit Line Rate.

The congruence of the technical ability to perform a large number of functions and therefore provide a wide range of services over telecommunications networks, together with a worldwide political climate which is allowing - indeed encouraging - a more open and competitive environment in telecommunications has led to an explosion in the demand for bandwidth. Thus, within four years of the first digital optical transoceanic system going into the water, we have moved through three generations of undersea fiber optic technology: 280 Mbit/s at 1.3 microns, 420 Mbit/s at 1.3 microns and 560 Mbit/s at 1.5 microns. Typically, as the first model of one generation goes into the water, the next generation is ready to move out of the lab and into production. At this stage, however, it becomes an interesting debate as to which is the next step forward in optical technology. In terms of wavelength, there is nowhere to go at present beyond 1.5 microns. In terms of bandwidth the next logical step is an increase of either one or two octaves and the general view is at this stage two octaves are needed. The open question is the technology which will be used to realize the first generation of Gigabit systems.

Optically amplified systems have been under development for some time. Although there is no question that the optically amplified system is the system of the future, it is not necessarily the system of the present or even the near future.

Conceptually the optical amplifier is the answer to the submarine cable planner's prayer. In the early days, the vision was of an optical pipe transparent to bit rate so that as the demand for bandwidth grew it was merely necessary to change the terminal equipment to upgrade the system. However, as usual, life is not that simple. The process of converting the optical amplifier from a concept to a reality has thrown up a number of problems which need to be resolved. For example, it is proving difficult to concatenate enough optical amplifiers to make a transoceanic span at an economic line rate. The dream of the optical pipe is tempered by the reality that an optically amplified system bandwidth is dependent upon repeater spacing. An upgradeable optically amplified system will therefore have to be planned and designed as such and thus will be more expensive than a non-upgradable system.

Two or three years ago, it was anticipated that transoceanic optically amplified systems would be installed in 1994. The latest forecast for the optically amplified TPC-5 system in the Pacific is for completion well into the second half of the decade. The implications of this can be seen by the HAW-5 cable consortium proposing to use its backup fiber pair for traffic growth instead of using it as designed for protection since, other than Aloha, the next increment to Hawaii-mainland capacity is dependent upon implementation of the still developmental optically amplified technology.

633

Thus, although the optical amplifier remains the system of the future, it unfortunately still is the system of the future, while the need for higher bandwidth grows inexorably. Thus, it is now clear that there is a need for a generation of regenerative repeater systems operating at 2.5 Gbit/s. Aloha will be one of these. The use of a regenerative system for Aloha is conditioned by the recognition of the need for extra capacity next year and the fact that with the short optical amplifier spacing currently predicted at 2.5 Gbit/s, a regenerative system is a more economic solution on the longer term.

STC Submarine Systems' NL 16 system has been in development since 1989 and moves from the laboratory into production shortly. The system is in an evolutional development of STC's 280, 420, and 560 Mbit/s systems with new components and techniques necessary to accommodate operation at 2.5 Gbit/s. Although a new laser, a new detector and a new silicon process are being deployed, the component development is far less fundamental than the developments associated with optical amplifiers. Likewise, the system development is modest compared with the system development associated with the first generation of optically amplified systems.

3.3 Synchronous Transmission.

Traditionally, submarine cable systems have been designed to have a 25 year life. In this respect, the Aloha Cable and its NL 16 technology is no exception. However, when we consider that the last coaxial analog transoceanic submarine cable system went into service in 1987, and therefore has a physical life expectancy to 2012, it is clearly necessary to make as much effort as possible to protect against changes in the future to the extent possible. In three years time it will be 1995 and we will be calling for 20/20 vision to see what we need over the lifetime of our systems.

One of the earliest contributions to the need of 20/20 vision forward rather than backwards is the designing of the system as a synchronous networking transmission system. Synchronous Optic Networking (SONET) standard transmission facilities are beginning to be implemented by U.S. common carriers in their respective networks. The introduction of SONET into the U.S. network will provide the basis for broadband switched networking by the mid-1990's and form the foundation upon which broadband ISDN is implemented for the second half of the decade and beyond.

As a result, although we do not envisage a significant requirement for SONET transmission next year, it is envisioned that it will be a necessary requirement very early on in the working life of the system. Recognizing that operators will expect to have most of their networks configured in synchronous mode during the lifetime of the system, Aloha's NL 16 system has therefore been designed to be a SONET system from the outset with the ability to handle either plesiochronous (e.g., DS-3) or synchronous traffic (e.g., STS-1). For the purchaser of capacity in Aloha there will be the option of DS-1, DS-2, DS-3 or SONET STS-1 or STS-3 interfaces together with the option to convert from a plesiochronous input to a SONET standard input at any point in the future.

3.4 Terminal Equipment.

Traditionally, repeatered submarine cable systems have had custom designed terminal equipment which handled the multiplexing and line interfacing. For the Aloha NL 16 system, TTL's supplier, STC, has adopted a new approach. The system will be based on standard terrestrial transmission equipment, in this case the Northern Telecom OC 48. This is being augmented by a line interface equipment which will convert the output of the OC 48 into a 24B1P line code with the corresponding increase in line rates. This will allow the supervision of the system to be carried out outside the overhead of the synchronous system. It also gives the opportunity to allow Synchronous Digital Hierarchy (SDH) terminal equipment to be used where the user's requirement is for a CCITT compatible system as opposed to a North American SONET-based system.

4. SYSTEM DESCRIPTION.

The Aloha submarine fiber optic cable system will transverse the Pacific Ocean between Oregon and Hawaii. The system will operate at a SONET standard OC-48 (2.488 Gbit/s) channel transmission capacity although the actual rate over the cable will be at 2.592 Gbit/s in order to accommodate the submarine cable's supervisory system as described in the previous section.

The system is such that a single fiber pair (each fiber of the pair operates in the reverse direction of the other) operates at 2.5 Gbit/s end to end to provide the OC-48 optical channel. The OC-48 channel will then be converted at the Aloha terminating facilities to electronic signals and mux'd down to lower data rate digital signals.

Throughout the system, on every cable path, there will be a complete redundant fiber/regenerator path which will be switchable on a section by section basis to allow remote replacement of any failed section. In addition, at a location at 1500-2000 meters in ocean depth, a branching unit will be placed. From the

location of the branching unit through shallower waters to the shore, two identical cables will span, each to one of two widely spaced landing stations. The landing stations will be interconnected through the respective Aloha terminal stations at each end of the system. Each branching unit will be remotely switchable such that either leg or branch may be employed at any given time.

The Aloha Cable will span a distance of about 4500 km. It will be comprised of about 4800 km of cable, 62 regenerative repeaters, two underwater branching units and four landing stations, two on each end. The landing stations will each contain terminal equipment for the submarine portion of the system, interface equipment for the terrestrial fiber, system supervisory equipment, and redundant generator and uninterruptible power supplies to allow seamless operation in the event of commercial power failure.

The two Oregon landing stations will connect to terrestrial fiber facilities to interconnect the submarine system to Aloha terminating facilities in Portland, Oregon. Similarly, the two Oahu landing stations will interconnect with terrestrial fiber facilities which will interconnect the submarine system to Aloha terminating facilities in Honolulu, Hawaii.

TTL will interconnect with its customers, common carriers and others, at the respective terminating facilities in Portland and Honolulu. Interconnection will be at the DS-1, DS-2, DS-3, STS-1, or STS-3 level depending upon individual customer needs. TTL will also have the ability to extend beyond the terminating locations by interconnecting customers to other submarine cable systems in Hawaii and in the Oregon area as well as extending terrestrially to other locations.

5. SUMMARY.

The Aloha Cable represents a significant opportunity for common carriers to secure capacity in a high capacity digital system at a time when capacity is in short supply between the continental U.S. and Hawaii. By offering a SONET standard system, TTL is giving its customers the opportunity to use a hierarchy which is likely to be standard over most of the 25 year projected life of the system. By implementing the self restoring architecture, TTL is giving an answer to the problem of what to do if a fault occurs, enhancing the availability of the system significantly.

The Dynamically Changing Regulatory Climate for Foreign Investment in United States Telecommunications Companies

Andrew D. Lipman and Helen E. Disenhaus
Swidler & Berlin, Chartered
3000 K Street, N.W.
Washington, D.C. (20007), U.S.A.

1. ABSTRACT

In response to the extraordinary interest in recent years by foreign nationals from the Pacific Rim and other countries in investing in the United States telecommunications industry, this paper identifies and discusses United States statutory and regulatory restrictions on foreign ownership of United States telecommunications facilities, and how best to structure arrangements consistent with that regulatory scheme. While most restrictions are intended to ensure that control of such facilities remains in the hands of United States citizens, certain regulations are intended to provide information and leverage that may help to minimize discrimination against United States common carriers in foreign markets. The article suggests ways of facilitating foreign investments that do not contravene U.S. ownership restrictions, and also notes recent indications that certain agencies of the United States Government may now be reasonably receptive to considering relaxing some or all of these ownership restrictions, at least to the extent of affording reciprocity to citizens of other countries that allow open market entry by United States firms. Given the increasing receptivity of some governmental offices to allowing greater foreign investment and favorable timing for such investment, we suggest various ways of facilitating arrangements between foreign entities and U.S. telecommunications companies.

2. INCREASED INTEREST BY FOREIGN FIRMS IN ENTRY INTO THE UNITED STATES TELECOMMUNICATIONS MARKET

In the past several years, foreign nationals and firms have become increasingly interested in investing in United States telecommunications companies. For example, Cable and Wireless recently agreed to acquire TRT/FTC, a leading international data and voice carrier, and British Telecom has acquired a significant interest in McCaw Cellular Communications Inc., one of the United States' largest cellular telephone system operators. Foreign telecommunications administration from a number of European countries have already or are rumored to be making significant U.S. telecommunications investments. Moreover, private companies, such as Swissair, not primarily known abroad for their communications interests, have also invested in U.S. telecommunications firms. More recently, much interest among non-U.S. companies and foreign governments has been generated from the Pacific Rim area. The acquisitions of interests in U.S. firms with motion picture studios, such as Sony's acquisition of Columbia Pictures, and Matsushita's acquisition of an interest in MCA, Inc., have made headlines. The most recent of these investments to receive substantial public attention was C. Itoh's and Toshiba's investment in the Time-Warner media conglomerate.

As Rupert Murdoch's much-publicized exchange of Australian for U.S. citizenship to permit U.S. media acquisitions demonstrates, however, the nature and scope of many of these investments is substantially affected by United States laws and regulations restricting ownership of communications firms.(1) Acquiring a significant interest in a United States telecommunications carrier has consequences that are materially different from those of investing in most other U.S. properties, as well as from those of investing in foreign telecommunications entities.

Foreign ownership and investment in the operations of a U.S. carrier triggers a wide variety of federal statutes, Federal Communications Commission ("FCC") rules, and other restrictions whose impact largely turns on the nationality of the purchaser and the scope and nature of its operations abroad. Moreover, given various recent regulatory, tax, and international trade developments, this area of the law is undergoing significant change and reexamination both in the U.S. and abroad.

Based on our recent first-hand participation in negotiating and arranging for foreign ownership of U.S. telecommunications properties involving a variety of different nationalities, this article sets forth and comments upon the regulatory scheme affecting U.S. investments by foreign commercial interests and foreign entities. The paper traces the background of

the alien ownership restrictions of the 1934 Communications Act, as it applies to radio licensees, satellite and microwave carriers, and broadcasters, and highlights indications that the regulatory environment may become more receptive to at least reciprocal relaxation of current ownership restrictions. Finally, the paper not only identifies many of the significant ownership restrictions, but also discusses a variety of corporate/financial structures and regulatory strategies to mitigate or circumvent the seemingly inflexible statutory restrictions and bans of the 1934 Act and promote arrangements between foreign investors and U.S. telecommunications firms.

3. RESTRICTIONS ON FOREIGN OWNERSHIP OF TITLE III RADIO LICENSEES

3.1 ORIGIN OF AND OPPORTUNITIES FOR CHANGES IN OWNERSHIP RESTRICTIONS

As a general matter, foreign ownership of firms holding radio licenses (including such authorizations as radio broadcast, microwave, satellite, and cellular licenses) regulated under Title III of the Communications Act(2) is much more restricted than is the ownership of firms holding non-radio authorizations. The ownership of broadcast station licensees is the most heavily scrutinized, and ownership of holders of common carrier authorizations is more restricted than ownership of holders of private carrier authorizations.(3)

The current restrictions are the result of a statutory prohibition included in the Communications Act. The antecedents of these restrictions were included in the Radio Act of 1927,(4) for, following World War I, fear of use of radio in aid of espionage or sabotage by a potential enemy led to imposition of the original restrictions on foreign ownership of radio facilities.(5) Interestingly, this statute, designed to prevent espionage and sabotage during war at a time when communications was in its infancy, and few carriers existed, has been stretched virtually beyond recognition to bar many foreign investments in today's highly competitive high technology concerns, even by the most loyal allies of the U.S. Very recently, however, Bush Administration officials and other U.S. regulators have begun to give serious consideration to relaxing these restrictions. The FCC's Chairman Sikes, for example, has spoken out against "parochialism" in U.S. and foreign regulatory processes and has made a commitment to "building international relations among communications policymakers."(6) Chairman Sikes is also on record as stating that "protectionism is self-defeating," and went on to say not only that the statutory ownership restrictions "date back to another technological and commercial era," but also that the FCC and the Bush Administration "strongly support open international investment with very limited national security exceptions."(7) Similarly, Assistant Secretary of Commerce, Janice Obuchowski, Administrator of the National Telecommunications and Information Administration, and the Bush Administration's spokesperson on telecommunications issues, has recommended that the U.S. consider easing restrictions even on foreign ownership of U.S. broadcast outlets.(8) (Nonetheless, it should be noted that Chairman Markey of the U.S. House of Representatives' Telecommunications Subcommittee and others have recommended expanding the coverage of the statutory alien ownership restriction to cover cable television and certain other new technologies.)(9)

At this time, it is therefore critical for potential foreign investors not only to be cognizant of the scope of U.S. ownership restrictions, but also to monitor the U.S. regulatory environment closely so that they may identify significant potential changes promptly and consider appropriate responsive actions.

3.2 SCOPE OF OWNERSHIP RESTRICTIONS

Under the current regulatory scheme, the only absolute restriction on foreign ownership of U.S. radio licensees applies only to foreign governments. Specifically, Section 310(a) of the Communications Act prohibits a foreign government, or its representative, from holding any radio license. This prohibition applies even to a private radio license, and it is the only statutory prohibition that does apply to private radio licenses. Thus, in the satellite radio context, the FCC recently scrutinized an applicant's partnership documents to determine under Section 310(a) that foreign government investors had no control of a private satellite system applicant.(10)

The other statutory restrictions, however, do not impose a complete ban on foreign investment in radio licensees, and are inapplicable to interests in private radio licensees. Section 310(b) of the Communications Act prohibits a broadcast, common carrier, or aeronautical en route or aeronautical fixed radio license's (but not a private radio license's) being granted to or held by a corporation (1) having an officer or director who is an alien or a representative of an alien; (2) organized under the laws of a foreign country; or (3) having 20% or more of its stock under foreign ownership or control (that is, owned or voted by one or more aliens or foreign governments, or their representatives, or foreign corporations).

Under a related statutory provision, however, a foreign investor may acquire a somewhat larger interest, so long as it is held indirectly. Under Section 310(b)(3), and subject to the discretion of the FCC, a tiered ownership structure may be utilized to allow this greater indirect foreign ownership. Thus, the FCC may issue licenses to a corporation controlled directly or indirectly by another corporation where non-U.S. citizens comprise less than 25% of the parent company's board of directors, and less than 25% of the parent company's stock is

BEST COPY AVAILABLE

foreign-owned. The parent company may not, however, have an officer who is not a U.S. citizen.

This discretionary indirect ownership "safe harbor" provision has also been applied to insulate certain foreign-owned partnership interests. In such cases, for purposes of analogizing partnership interests to corporate counterparts specified in the statute, general partners are treated as corporate officers, although limited partners may be treated as corporate shareholders if their ability to participate in partnership activities is sufficiently limited under specific Commission standards.(11)

The Section 310 requirements, being statutory, are very strictly applied. Thus, publicly-traded U.S. communications firms must have their stock transfer agents closely monitor levels of foreign holdings. Matsushita's acquisition of MCA, Inc., also illustrates the impact of the statutory restrictions, for the New York City television station owned by an MCA subsidiary had to be spun-off prior to the completion of the corporate acquisition to avoid violation of the foreign ownership limitations.

3.3 PERMITTED INVESTMENTS IN COMMON CARRIER AND BROADCAST RADIO LICENSEES

The potential foreign investor does, however, have a number of avenues for investing in U.S. firms holding radio licenses. With respect to broadcast or common carrier firms, as suggested above, a two-tiered corporate structure is the most common investment vehicle for increasing foreign participation. Frequently, a U.S.-incorporated holding company is formed to be the parent of the license-holding operating subsidiary to ensure that there is at least one corporate tier between the foreign ownership interests and the telecommunications licensee. Because the foreign ownership interest in the licensee's stock (voting and non-voting) is indirect, it may reach the 25% level, and non-U.S. citizens may hold 25% of the seats on the board of directors of the holding company parent firm.

In some cases, it may be possible to obtain a waiver of this ruling from the FCC if a higher level of foreign investment is desired. For example, in one recent case, the FCC found that an indirect interest of 26.6% represented a *de minimis* extension above the benchmark.(12) In the same case, however, the FCC deferred action on the applicant's request to be permitted to have indirect alien ownership of 49.9%. Thus, the FCC might be open to considering a 30% foreign indirect interest, particularly in a common carrier facility, but is likely to be less receptive to considering interests that approach the *de jure* control level.

In ruling requests, the FCC will consider a number of different factors, including:

1. Whether the foreign parent company is publicly held;

2. Whether the ownership interests are held by foreign governments;

3. The percentage of alien officers and directors;

4. Whether the licensees are common carrier rather than broadcast licensees, and thus do not have an opportunity to initiate or control transmission content;

5. The degree of the licensee firm's need for working capital;

6. Whether the investment facilitates participation by the U.S. firm in ventures abroad or assists it in obtaining foreign operating agreements;

7. The relationship of the foreign owner's domiciliary country with the United States; and

8. The potential impact of the proposed transaction on the industry involved, including antitrust and competitive implications and the need for capital or technology for new services.

It should also be noted that there are generally no statutory limitations on foreign investments if they take the form of loans and debt securities. Traditionally, the FCC has not recognized even warrants or convertible debentures as equity securities until the conversion rights are exercised.

Another approach that may be utilized to permit increased levels of foreign investment is to review the nature of the firm's business activities. If what is critical to the continuation of its activities is not necessarily control of the radio licensed facilities, but merely the opportunity to obtain the radio-based services they afford, it may be possible to spin off the licenses to a separate firm that has no alien ownership in an arms-length transaction.(13) Under certain carefully designed conditions, the newly-formed licensee firm would provide services (such as transmission capacity) to the now license-free foreign-owned firm. For example, if foreign investors wish to acquire a facilities-based microwave interexchange carrier, they could instead operate the business as a reseller of capacity of a new firm established on a *bona fide* arms-length basis that is the assignee of the microwave licenses.(14)

Another alternative to consider is whether the firm could essentially carry on its business activities as a private, rather than a common, carrier.(15) In many situations, the

distinctions between common carrier and private carrier activities have become blurred by the FCC's forbearance with respect to most federal regulation of nondominant domestic carriers. Yet there are virtually no limits on foreign holding of private radio licenses except those applicable to foreign governments.

3.4 PERMITTED INVESTMENTS IN PRIVATE RADIO LICENSEES

There are fewer restrictions on foreign ownership of private radio licensees, because they are subject only to the provisions of Section 310(a). This provision only precludes issuance of licenses to foreign governments and their representatives, although it applies to both domestic and international facilities. Private carriers that carry third party traffic may operate microwave, satellite, and transoceanic cable facilities. For example, the PTAT private transatlantic fiber optic cable, which offers capacity to both carriers and end-users, was initially structured as a private carrier.(16) PanAmSat has initiated private satellite service as a separate satellite system operator.(17) Various microwave service providers offer end users domestic private microwave services via facilities licensed in the domestic Private Operational Fixed Service ("POFS").(18) Where facilities are to be utilized for the exclusive use of the licensee, even 100% foreign ownership may be authorized, as indicated by the Reuters decision, involving foreign ownership and operation of an Intelsat Business Service earth station used to transmit news reports in furtherance of Reuters' business of providing news stories to customers.

It should be noted, however, that private and common carrier facilities are not necessarily completely interchangeable. For example, POFS facilities may be interconnected with the public switched telephone network ("PSTN") only for transmission of business-related communications.(19) With respect to separate satellite systems, at this time interconnection with the PSTN is prohibited, although PanAmSat has requested that the FCC lift the prohibition.(20)

4. DOMINANT CARRIER TREATMENT OF CERTAIN FOREIGN-OWNED TITLE II INTERNATIONAL COMMON CARRIERS

In addition to the statutory restrictions on the ownership of radio licensees, there are also certain regulatory requirements imposed by the FCC as a matter of policy that are applicable only to certain foreign-owned international common carriers, whether or not they hold radio licenses. Unlike most foreign telecommunications markets, the United States common carrier market is open to participation by foreign-owned carriers, whether they are facilities-based carriers or resellers.(21) With respect to their domestic services, foreign-owned interexchange carriers are treated no differently from their U.S.-owned competitors, and are largely free of federal regulation. Certain foreign-owned interexchange carriers that offer international services are, however, treated as dominant carriers with respect to their international services, and are thus subject to additional regulation for both their domestic and their international services.

The foreign ownership issue arises in the context of an application for authority under Section 214 of the Communications Act (a "Section 214 application") to provide international services on a facilities-based or resale basis, or to obtain a transfer of control of a company already holding a Section 214 international authorization. In order to promote reciprocal treatment of U.S. carriers abroad, in certain situations the Commission will condition the grant of the requested authority on dominant carrier classification of the carrier with respect to its international services.(22) In some situations, a carrier may be treated as dominant only with respect to its service to a particular country.(23)

With respect to the international services of foreign-owned U.S. carriers, whether facilities-based or pure resellers, the FCC will impose dominant carrier regulation if one of the following circumstances is involved:

> 1. The carrier's board of directors includes a foreign government, a foreign PTT, a "foreign telecommunications entity," or a representative of one of such foreign entities; or
>
> 2. A foreign government, a foreign PTT, a "foreign telecommunications entity," or a representative of one of such foreign entities, holds a direct or indirect capital stock interest (including non-voting and preferred as well as common voting stock) of 15% or more

While the Commission may waive the 15% benchmark in cases in which it finds interests to be passive, it may also impose dominant carrier classification even in the case of debt relationships and equity relationships of less than 15% if they are not passive.

The most difficult problem, however, is interpreting the scope of the regulations, because the FCC has never explicitly defined what activities would cause firms to be characterized as "other foreign telecommunications entities." The FCC's intent is apparently to reach all foreign entities that may be in a position to exercise influence with foreign governments with respect to their telecommunications policies.

The FCC therefore extends the dominant carrier classification to telecommunications-related equipment manufacturers, suppliers, and service providers in an apparent effort to reach all entities with market power in their own

countries that could be used to exclude U.S.-owned firms from business abroad. The FCC clearly intended to reach such large non-U.S. telecommunications equipment manufacturers as Germany's Siemens or Sweden's Ericsson, in the event that either formed or acquired a U.S. interexchange carrier ("IXC") subsidiary with an international service Section 214 authorization. The definition of "foreign telecommunications entity" is so ambiguous, however, that in practice it seems to be applied to all foreign ownership interests, regardless of how tenuous or attenuated the connections of the parent to the foreign telecommunications industry or the potential clout of the parent firm at home.(24) Thus, it has apparently been applied to impose dominant carrier status on international IXCs affiliated with a wide variety of non-U.S. entities, including those involved in customer premises equipment, data processing, telecommunications consulting, as well as other lines of business more traditionally considered to be telecommunications activities.

The problem of dominant carrier regulation, however, is somewhat mitigated by the fact that the consequences of dominant carrier classification, while imposing administrative and other not inconsequential costs on carriers and some loss of flexibility in changing service offerings, are not so burdensome as totally to foreclose a carrier from competing effectively in the market. The additional requirements include:

1. Tariffs for international services must be filed on 30 days' notice.

2. Tariffs for international services must be accompanied by economic and cost support data.

3. Section 214 approval must be received from the FCC not only for initiation of service to a country (a requirement also applicable to non-dominant carriers) but also for modification of facilities or increases in circuits to a country.

4. Carriers must file their own and their parent or affiliated firms' operating agreements affecting traffic and revenue flows to or from the United States.

5. Carriers must file traffic and revenue reports with respect to their domestic services (although nondominant international carriers must file such reports only for their international services).

The issue of affiliation with a "foreign telecommunications entity" appears to have been raised most often when a competitor challenges a transfer of control of an international carrier and the proposed transferee is owned in part by foreign interests. In order to expedite the approval of the transfer of control application, the transferee may agree to accept dominant carrier classification on a temporary basis, subject to the filing of a request for termination of the classification and the FCC's approval of that request. Despite substantial documentation by several carriers of the lack of justification for the classification in their particular cases, however, to date the FCC has declined to act on any of the requests, which have in some cases been pending for years, and thus there has been no narrowing, or even clarification, of the definition of a "foreign telecommunications entity."(25)

Significantly, as a result of this inaction by the FCC, Cable & Wireless filed in December 1990 a petition requesting initiation of an FCC rulemaking proceeding seeking to have the FCC relax and identify with specificity the criteria for subjecting U.S. carriers with foreign ownership to dominant carrier regulation.(26) The petition argues that, at most, such regulation should be imposed only with respect to the carrier's "home" country, and only if the home country discriminates in some way against U.S.-owned carriers. One more lenient approach that has been suggested is for the FCC to limit its definition of "foreign telecommunications entity" by identifying those activities of a foreign affiliate that enable it to affect market entry by U.S. carriers, and not classifying a foreign affiliate as a "foreign telecommunications entity" if it does not engage in such activities. Another suggestion is that the FCC develop a process (such as adjudication of complaints by other carriers) for determining whether a foreign owner is in fact adversely affecting market entry by U.S. carriers in its home or other foreign countries, and issue authorizations subject to dominant carrier classification if the FCC finds the parent to have influenced market entry abroad.

Cable & Wireless' efforts in this proceeding parallel its efforts in other contexts, such as use of international private lines, that are apparently intended to force the FCC to address areas in which its requirements may be more stringent than those of other European administrations, such as the U.K., or where greater market entry rights for U.S. carriers abroad may be contingent on greater openness in the U.S. To date, however, the FCC has not yet initiated the requested rulemaking, and the dominant international carrier classification policy continues to be broadly applied.

5. SUBMARINE CABLE LANDING LICENSES

Like the use of dominant carrier regulation of foreign-owned international interexchange carriers, the submarine cable landing license law is now utilized chiefly to secure leverage to promote U.S. interests abroad. Initially, however, like the statutory restrictions on radio license holding, it was enacted after

World War I largely as a result of concern arising from German and U.K. dominance in the ownership of transatlantic cables.

Pursuant to the Submarine Cable Act of 1921, 47 U.S.C. § 34, the FCC, in coordination with the U.S. Department of State, is authorized to grant licenses for the landing of submarine telecommunications cables in the United States. While traditionally these cables have been owned by consortia of common carriers and capacity has been made available on a common carrier basis, in recent years several private fiber optic submarine cable systems have been established, including the PTAT-1 transatlantic cable and the North Pacific Cable ("NPC") transpacific cable.(27)

The statute specifically provides that licenses may be granted and withheld based on determinations as to the relative involvement of U.S. and foreign interests in the project and determinations of whether U.S. interests are receiving sufficiently reciprocal treatment by the foreign governments involved. While the FCC does not necessarily require that U.S. interests hold a half-interest in the project as a whole and be treated exactly in the same manner as their foreign partners, it will look to several factors to determine whether the benefits to the U.S. participants are sufficient. These factors include: 1) The proportion of U.S. to non-U.S. interests in the project; 2) the fairness of the contract procedures and opportunities for U.S. contractors to participate in the project; 3) the relative importance of the project to the public; and 4) the opportunities the project affords for U.S. investment abroad, including the degree of reciprocity shown U.S. interests abroad.

There are no specific standards to be applied in this analysis, so the determination may be quite fact-specific and may be affected by particular international policy concerns at the time the decision is made.

Ideally, from the FCC's perspective, the U.S. interests would own the entire U.S. "backhaul" network to connect the cable with carrier points of presence ("POPs"), would own one-half of the undersea cable system, and would receive one-half of the contracts awarded to construct the project. Recognizing that requiring complete equivalence is not always practical, however, the FCC will generally be satisfied if the first two conditions are met, U.S. interests receive reasonably reciprocal treatment abroad, and the contracting process ensures that U.S. firms have a real opportunity to obtain a reasonable proportion of the construction and maintenance contracts for the project.

Insofar as a project may represent one of the first opportunities for significant U.S. investment in a particular foreign telecommunications market, the FCC may also relax its policy with respect to the degree of reciprocity shown U.S. interests abroad. Thus, the FCC has interpreted the Submarine Cable Act in several instances to mitigate foreign ownership of several Pacific Rim cables. On the other hand, the FCC, because of looming international trade considerations and Congressional pressure, has been more vigorously scrutinizing and at least threatening to enforce more vigorously these provisions, at least as to certain trading partners.

6. CONCLUSION: TAKING ADVANTAGE OF CHANGING REGULATORY ATTITUDES TOWARD AND OPPORTUNITIES FOR FOREIGN INVESTMENT

There are numerous opportunities now for substantial foreign investment in U.S. telecommunications firms, and there are signs that the opportunity may exist for foreign firms to acquire even larger interests in U.S. firms in the future through possible Congressional relaxation of current statutory restrictions and FCC relaxation of certain regulatory policies. Foreign nationals cannot make U.S. telecommunications investments, however, without carefully considering the current U.S. restrictions on and policies affecting foreign investment in a particular industry segment. By careful planning, investors can structure proposed investments so as to avoid any preclusive restrictions, can facilitate timely grants of necessary approvals, and can minimize the degree of regulation to which a business may be subject.

Where U.S. policies are based on the availability of reciprocal treatment of U.S. interests abroad, careful review of national policies in the "home" country, and approaches to promoting reciprocal treatment of U.S. interests there, may also be helpful in bringing a contemplated U.S. investment to a successful consummation. Additionally, potential investors can work in the U.S. to promote the continued openness of various FCC and administration officials to recommending legislation that would give them the discretion to relax the statutory requirements, at least in response to a reciprocal opening of foreign markets to U.S. investors. Due in part to increasing pressure from U.S. carriers seeking access to increased levels of foreign investment capital, there is a growing sentiment that foreign investors from a nation whose telecommunications infrastructure is relatively open to competition from U.S. market entrants (e.g., United Kingdom) should be relieved from this statutory bar, particularly as U.S. carriers seeking entry in foreign markets are met with the response that concessions abroad may be dependent on an open entry policy at home. Thus, this is an opportune time for foreign investors to consider entry and increased investment in the U.S. telecommunications market.

ENDNOTES

1. There are, however, a substantial number of important types of investments in United States communications firms that do not implicate any foreign ownership restrictions. For example, there are at this time no restrictions on foreign ownership of U.S. cable television systems, movie studios, consulting services, information services providers, computer services, or equipment manufacturers. In the telecommunications area, there are no restrictions on ownership of domestic interexchange carriers or resellers, local exchange carriers ("LECs"), or competitive access service providers ("CAPs"), provided that they do not hold radio authorizations. Thus, in addition to common carrier firms such as Cable & Wireless, equipment manufacturers such as Siemens and Rockwell-Alcatel have active U.S. affiliates. (We note, however, that Public Law 100-418, 102 Stat. 1107 (1988), popularly known as the Exon-Florio Act, does allow the President to delay, prohibit, or require unwinding of any investment in any U.S. firm, in any industry, that is deemed to be a threat to U.S. security interests. To date, there has been formal action in only one situation, and that did not involve the communications industry.)

2. 47 U.S.C. § 301 et seq. (1988).

3. Private radio authorizations may be obtained for operation of such facilities as microwave and satellite systems, as well as for use by special types of users, such as motion picture companies, power companies, and emergency services. In a number of services, authorizations may allow facilities to be shared with other eligible users, even on a for-profit basis.

4. Radio Act of 1927, Ch. 169, 44 Stat. 1162, 47 U.S.C.A. 81 et seq. (repealed 1934).

5. See, e.g., Remarks of Chairman Alfred C. Sikes, "Globalization of the Telecommunications Market: Foreign Investment Issues," before the European Institute's Conference on "European Investment in the United States: Unity and Fragmentation in the American Market" (Sept. 23, 1991) ("Sikes' Sept. 23 Speech") at 4-5; Remarks of Janice Obuchowski, "Media Globalization From Prophecy to Fact of Life," (Sept. 13, 1991) at 7; see also, Continental Cellular, FCC 91-355 (released Nov. 20, 1991) at 3 (citing 68 Cong. Rec. 3037 (1927)). The communications industry is not unique in having such statutory ownership restrictions. See 16 U.S.C. § 797(e) (barring dam construction license grants by the Federal Power Commission to aliens and alien-controlled entities); 33 U.S.C. §§ 1502(5), 1503(g) (limiting ownership and operation of deep water ports to U.S. citizens and corporations); 42 U.S.C. §§ 2133, 2134 (barring the issuance of nuclear power plant licenses by the Nuclear Regulatory Commission to aliens, alien-controlled corporations, and foreign governments); 30 U.S.C. § 1015 (geothermal production leases on federal lands authorized only for U.S. citizens, corporations, and governmental entities); 10 U.S.C. § 2272 (restricting awards of aeronatical design contracts to corporations with less than 25% alien ownership).

6. Remarks of Alfred C. Sikes before the Columbia University Business School's Institute for Tele-Information, Special Evening Symposium on International Regulatory Agenda for the 1990s (Nov. 4, 1991).

7. See Sikes' Sept. 23 Speech; FCC News, Mimeo No. 14896 (Sept. 23, 1991).

8. "Obuchowski Calls Ownership Restrictions Solution in Search of a Problem," Comm. Daily, vol. II, No. 179 (Sept. 16, 1991) at 1.

9. "No Must-Carry Deal; Markey's Program Access Provisions Draw Cable Opposition," Comm. Daily, Vol. 10, No. 123 (June 26, 1990) at 1.

10. See Orion Satellite Corporation, FCC 90-241, File No. CSS-83-002-P-(M).

11. See Wilner & Scheiner, 103 FCC 2d 511 (1985), reconsidered in part, 1 FCC Rcd. 12 (1986) (holding that the alien ownership prohibition "applies equally to all financial interests in all business forms of licensees"); Reexamination of of the Commission's Rules and Policies Regarding the Atrribution of Ownership Interests in Broadcast, Cable Television and Newspaper Entities, 97 FCC 2d 997, 1009 (1984), reconsidered in part, 58 Rad. Reg. (P&F) 2d 604 (1985), further reconsidered, 1 FCC Rcd. 802 (1986) (collectively, "Attribution Orders"). In Wilner & Scheiner, the Commission stated that it would look to the standards for insulation of limited partners from attribution of ownership in determining whether a limited partner that was not a U.S. citizen was sufficiently insulated from participation in partnership activities to warrant ignoring the interest for purposes of the alien ownership restrictions. Recently, in Continental Cellular, FCC 91-355 (released Nov. 20, 1991) ("Cellular Foreign Ownership Decision"), the Commission relied on the Wilner and Scheiner decisions and upheld its staff's dismissal of 21 applications for cellular radio authorizations. (In 20 cases, at least one of the general partners was not a United States citizen, and, in one case, a limited partner who was not a U.S. citizen was found to be insufficiently insulated from partnership activities.) The FCC also held that the alien ownership defect could not be cured with a minor amendment, citing 47 C.F.R. § 22.918(b), although this defect may be cured during an "amendment-as-of-right" period with respect to radio broadcast applications. The Cellular Foreign Ownership Decision included a succint summary of the insulation standards of the Attribution Orders:

> The Attribution Orders required that in order for a limited partner's interest not to be attributed the partnership agreement must state, in express terms, that the exempt limited partner is prohibited from becoming actively involved in the

797

> management or operation of the communications business of the partnership. Moreover, the exempt limited partner must not be allowed to vote for the removal of a general partner except for cause. Additionally, the limited partnership agreement must bar the exempted limited partner from serving, in any material capacity, as an independent contractor or agent. Finally, the exempt limited partner cannot act as an employee of the limited partnership if his or her functions, directly or indirectly, relate to the communications enterprises of the company.

Id. at n.22. The FCC also noted that a limited partner cannot use a private contract, rather than the terms of the partnership agreement, to insulate itself from management and thus secure an exemption from attribution. Id. at 7 n.23. The alien ownership restrictions have also been applied in cases involving other unicorporated interests, including mutual insurance company policyholders, Farragut Television Corp., 4 Rad. Reg. (P&F) 2d 350 (1965); members of a church, Kansas City Broadcasting Co., 5 Rad. Reg. (P&F) 1057 (1952); beneficial owners of irrevocable trust interests, Prime Media Broadcasting, Inc., FCC 88-218 (Jul. 12, 1988); and members of a labor union, Chicagoland TV Co., 4 Rad. Reg. (P&F) 2d 747 (1965).

12. See IDB Communications Group, Inc., 6 FCC Rcd. 4652 (1991).

13. The Commission is likely to scrutinize the transaction to ensure that the spin-off is in fact an arms' length transaction, and that the foreign owners do not gain de facto or other control of the new firm. See, e.g., Satellite Transmission and Reception Specialist Co., DA 90-927 (C.C. Bur. Jul. 13, 1990) ("STARS") (transaction initially disapproved as not being arms' length, but subsequent spin-off found to be acceptable and application for Secftion 214 authorization by the now-foreign owned firm approved). See also Licensee Limited Partnership 5 FCC Rcd. 1673 (1990); Com Systems, Inc., 5 FCC Rcd. 696 (1990).

14. To the extent that domestic microwave facilities are involved, and the new reseller does not offer international services, it would be regulated in the same manner as any other domestically-owned reseller. The Commission has adopted a policy of regulatory forbearance in most areas with respect to domestic resellers. See Competitive Carrier Services Docket (CC Docket No. 79-252), initiated by Notice of inquiry and Proposed Rulemaking, 77 FCC 2d 308 (1979); concluded by Sixth Report and Order, 99 FCC 2d 1020 (1985), rev'd sub nom. MCI Telecommunications Corp. v. FCC, 765 F.2d 1186 (D.C. Cir. 1985).

15. Private radio licenses may be issued to non-governmental foreign entities. Thus, Reuters obtained a private satellite system authorization to feed news reports to its earth stations at customer locations. Reuters Information Services, Inc., DA 89-899, File No. CSG-89-088-A (C.C. Bur. Aug. 3, 1989).

16. See Cable Landing Licenses, File Nos. I-S-C-L-84-002 and I-S-C-L-84-003, Mimeo No. 4618, released May 17, 1985; see also Tel-Optik, Limited, 100 FCC 2d 1033 (1985) ("Tel-Optik").

17. Establishment of Satellite Systems Providing International Communications, 101 FCC 2d 1046 (1985), on recon., 61 Rad. Reg. (P&F) 2d 649, on further recon., 1 FCC Rcd. 439 (1986).

18. See 47 C.F.R. § 94.1 et seq. Pursuant to the FCC's rules, POFS licensees may make their facilities available on a shared, and for-profit, basis to users that would themselves be eligible to be licensees of POFS facilities. 47 C.F.R. § 94.17.

19. See 47 C.F.R. § 94.13, 94.9.

20. See Petition for Rulemaking To Provide Fully Competitive Services, Including Services Interconnected with the PSTN, filed Jul. 18, 1990.

21. Carriers holding radio authorizations are subject to Title III foreign ownership limitations.

22. The implementing regulations are codified at 47 C.F.R. § 43.81. This policy was developed in the context of the Commission's proceedings concerning deregulation of international interexchange carriers. See International Competitive Carrier Policies, 102 FCC 2d 812 (1985), reconsideration denied, 60 Rad. Reg. (P&F) 2d 1435 (1986); Report and Order and Supplemental Notice of Inquiry, CC Docket No. 86-494, 64 Rad. Reg. (P&F) 2d 976 (1988) ("International Policies"), modified in part on reconsideration, 4 FCC Rcd. 323 (1989). Only nine carriers may be classified as dominant under this regulation because the FCC implemented the policy over the objections of the Office of Management and Budget ("OMB").

23. FTCC is classified as dominant with respect to its services to France because of its affiliation with the French Post, Telephone and Telegraph Administration ("PTT").

24. This policy, an attempt by the FCC to influence regulatory policies in foreign markets, is cited by foreign governments, particularly that of the U.K., in characterizing the United States telecommunications market as not truly open to foreign investment.

Telecommunications Regulation and Public Choice

ABSTRACT

Conventional theories of telecommunications regulation overlook two critical determinants of policy choice: (i) the self-interest of government decision-makers; and (ii) the countervailing effects of technology and market forces. Public Choice theory accounts for these factors, thus providing a positive basis for understanding and predicting the evolution of regulatory policy in the United States and abroad.

1.0 INTRODUCTION

Changes in telecommunications policy have come to be regarded as the triumph of economic reason over regulatory incoherence. This paper challenges the conventional wisdom by arguing that policy choice is merely an artifact of the tension between the self-interest of government decision-makers on one hand, and the inexorable tendency of market systems to move toward the efficient utilization of technology. This conclusion has important implications for policy "planners."

The first section below examines some of the more commonly held theories of regulation, and introduces the broader perspective of Public Choice theory. he next section analyzes some aspects of telecommunications policy in the United States through the lens of Public Choice theory, and the following section similarly analyzes some aspects of regulatory policy abroad. The paper is summarized in the final section.

2.0 THEORIES OF REGULATION

Several theories have been proposed over the years to explain the nature and function of regulation. Unfortunately, none of these theories, whether taken alone or in combination, adequately explains or predicts the course of telecommunications policy in the United States and abroad. These theories fail partly because they are normative and descriptive rather than positive and predictive, and partly because they do not account for the self-interest of government decision-makers and the influence of technological change and market forces. Public Choice theory provides a positive basis for understanding changes in telecommunications policy and for predicting its future direction.

2.1 CONVENTIONAL THEORIES OF REGULATION

Conventional theories of regulation can be divided into two groups for discussion purposes: (i) the "public interest" theory; and (ii) "political" theories.

2.1.1 THE PUBLIC INTEREST THEORY OF REGULATION

The public interest theory presumes that government decision-makers are benevolent and omniscient, and that legislative and administrative rules represent honest and narrowly-focused attempts to maximize social welfare. Regulation is intended to prevent the pricing, output, and distribution problems caused by natural monopoly and other market imperfections by substituting behavioral rules (e.g., earnings constraints and common carrier responsibilities) for market forces. Adherents to this theory sometimes admit that regulation does not always protect the public interest as effectively as intended, but assert that results would be more desirable if only regulations were more numerous and invasive and enforcement efforts were increased.

This view of regulation plays well in public forums, but has come to be regarded as naive by economists who focus upon: (i) the substantial direct costs and economic deadweight losses attributable to regulation [1]; (ii) the gossamer public benefits of many regulatory policies; and (iii) the fact that regulatory tools are a demonstrably poor substitute for market forces when it comes to constraining costs and prices, and to achieving efficient levels of service quality and innovation.

2.1.2 POLITICAL THEORIES OF REGULATION

Political theories of regulation acknowledge that regulatory practices represent more than the blind benevolence and wisdom of public officials. The theories cited most often are these:

- The status quo theory: The purpose of regulation is to moderate the ebb and flow of wealth redistribution between consumers and producers. The apparent failure of regulation to react swiftly and efficiently to changing market conditions actually is an example of regulation performing its intended function. A variation of this theory posits that the purpose of regulation is to buffer and balance the avarice of public utility firms against the confiscatory tendencies of majoritarian democracy.

- The mediation theory: Producers and consumers desire an independent third-party to mediate and arbitrate ongoing transactions. Regulatory agencies fill this role by providing the forum and ground rules for discussion.

- The social contract theory: Regulatory authorities act as consumers' agents by negotiating and administering long term contracts with suppliers. Some regulatory reform proposals in the United States have adopted the "social contract" label although they have no direct tie to either the "social contract" theory of regulation or the "contractarian" theory of libertarian political thought.

- The taxation theory: Regulation is an extension of the "tax and spend" function of government, and is used to redistribute public and private wealth in ways that would not be countenanced if attempted through legislation.

- The economic theory: Regulation initially is introduced in a public interest vein, but subsequently becomes a captive of special interest groups, especially groups comprising the industries being regulated. Interest groups "demand" (and bid competitively for) regulations that foster strategic objectives. Government "supplies" (sells) regulation in exchange for political capital, private sector jobs, and other rewards. Policy choice favors the highest bidder, and regulation is transformed into a lawful form of cartel management.

Each of these theories describes some observable aspects of telecommunications regulation, but no theory adequately explains -- or could have predicted -- the policy changes that have occurred in the United States over the last two decades. On the one hand, regulation has perpetuated the status quo by delaying both the introduction of new technology and services, and the entry of new suppliers. Similarly, the continued existence of regulation in the absence of natural monopoly conditions and serious market imperfections suggests a fundamental demand for regulatory services by suppliers and consumers. And the fluidity with which individuals rotate their employment among regulatory, legislative, legal, and industry venues, coupled with the use of regulatory "taxation" to build political capital by redistributing private wealth, provides some support for the pessimistic predictions of the "economic" theory.

On the other hand, none of these theories adequately explains some critical aspects of regulatory policy. Contrary to the predictions of the "economic" theory, for example, resourceful and politically powerful telephone companies were placed at a competitive disadvantage vis-a-vis small, entrepreneurial rivals. Moreover, the burdens of cross-subsidization inexplicably were concentrated among a relatively small number of high-volume toll users, while the benefits were spread across a politically unorganized body of residential exchange subscribers. The "taxation" theory is contradicted by the fact that deregulated services have been those that were taxed most heavily under regulation (e.g., toll services). And none of these theories predicts that a regulatory agency would adopt reforms that lessen the scope of its own responsibility and authority.

The shortcomings and contradictions of conventional theories reveal them to be merely normative and descriptive explanations of the regulatory process. As such, they are not particularly useful for predicting the course of policy change.

2.2 PUBLIC CHOICE THEORY

A more fruitful approach to understanding the foundations of policy selection is Public Choice theory, an analytical approach that uses constructs of economics to explain government (i.e., non-market) decision-making. Public Choice theory is similar in many respects to the "economic" theory of regulation, although its perspectives are both broader and more dynamic.

A fundamental premise of Public Choice theory is that government decision-makers (i.e., lawmakers, regulators, and courts) have private interests that are furthered through the policy choice process. These interests lead decision-makers to maximize non-market objective functions that include such variables as: (i) the likelihood of re-election or re-appointment; (ii) campaign contributions and other side payments; (iii) future employment opportunities; (iv) budget maximization; (v) personal self-esteem, power and prestige; and (vi) the satisfaction that comes from shaping society according to personal preferences. Accordingly, Pubic Choice theory views politicians and bureaucrats as entrepreneurs, and political parties as business organizations that produce economic rewards for their creators and patrons.

The self-interest of decision-makers is served in part by using the power of the state to redistribute public and private wealth (property rights) among competing interest groups. As proposed by the "economic" theory of regulation, decision-makers supply redistributive rules and regulations through a market-like process in response to the demands of constituents and other groups. Wealth redistributions are effected in many ways, including those described by the traditional theories of regulation; e.g., taxation, status-quo maintenance, etc. Where political self-interest dominates the public choice process, policies are consistent with the public interest only to the extent that public and private interests are coextensive.

In return for providing (or merely for promising and/or threatening to provide) redistributive rules, decision-makers receive votes and other private benefits (e.g., campaign contributions, self-esteem, etc.). These benefits are termed "rents."[2] The systematic pursuit of rents is termed "rent-seeking."

711

Rent-seeking is a predatory, non-productive, and socially wasteful activity. It is, however, a natural consequence of democratic social organization. Conferring legislative and regulatory authority on the state necessarily entails vesting decision-making authority in selected individuals. Once this authority is vested, it becomes a property right that decision-makers, as rational utility maximizers, have an incentive to exercise in ways that increase personal utility. In other words, there is an incentive for decision-makers to make choices that maximize the value inherent in the right to decide.

Public Choice scholars have shown that rent-seeking incentives can lead to policies that are both random and incoherent. A decision-making majority can (in theory) adopt virtually any conceivable policy given plausible sets of assumptions and circumstances. This understanding has led scholars (and an increasing number of judges) to dismiss the importance of "intent" when interpreting statutes and regulatory rules, not only because these rules are likely to be self-serving and mindless, but also because of the ease with which the underlying documentation can be deliberately distorted.

Despite strong empirical and anecdotal evidence, Public Choice theory frequently is criticized for its cynical premises and pessimistic predictions. A valid criticism of Public Choice theory is that it cannot predict a priori that all decision-makers always behave in a blatantly self-serving fashion, and that all policy choices necessarily are mindless and incoherent. However, the assumption that decision-makers, like all individuals, place positive value on self-interest provides a useful starting point for analyzing and predicting the course of policy choice.

Two relevant sets of forces check the ability of telecommunications regulators to pursue their self-interest. The first set comprises constitutional and statutory rules that prohibit confiscation of private property by the state. However, in countries like the United States where courts do not strictly enforce private property rights (except in the most egregious cases) where government "taking" is involved, parchment rules intended to check the expression of political self-interest via regulation can be of little practical consequence. Similarly, in countries where productive assets are owned and controlled directly by the state, checks against rent-seeking can have relatively little bite and, moreover, can be altogether absent.

The second set of forces checking political self-interest is technology-driven market forces. There is a tendency for organizational systems, both natural and man-made (political), to make efficient use of technology, even in the face of entrenched resistance. Competition for scarce resources provides an incentive for profit- and utility-maximizing individuals to employ the most efficient technology and methods available. In economies where competition for resources (and political power) is channeled through markets, technological change inexorably affects the private utility function of decision-makers by constantly creating new rent-seeking opportunities and eroding old ones. Policy choice tracks this ebb and flow.

This dynamic has shaped telecommunications policy in the United States, and is producing similar results abroad.

3.0 POLICY CHANGE IN THE UNITED STATES

Pressures to liberalize telecommunications policy in the United States grew out of microwave transmission technology and microprocessor-based switching systems. These technologies not only reduced the cost of telecommunications services, but also increased the quality and diversity of services that could be supplied. This, in turn, created pressure for decision-makers to conform regulatory policies to the state of technology. Pressure increased as the range of potential benefits grew to include the body of business and residential users.

Pressure for regulatory change initially was resisted by the Federal Communications Commission (FCC), state legislators and regulators, Congress, and the telecommunications industry establishment. One obvious reason for resistance was the breadth and depth of subsidies that had arisen as the result of falling unit costs. To decision-makers, these subsidies represented a stock of political capital and a source of decision-making rents. To the industry establishment they represented a source of wealth and x-inefficiency rents. These subsidies were not sustainable in the face of competitive supply and unrestricted user choice, and so resistance to policy change was inevitable.

Policy change was effected at the federal regulatory level well before any changes occurred at the state or federal legislative level. This suggests that the objective functions of the FCC and the federal courts were appreciably different from those of other cognizant decision-making bodies. Significantly, Congress has not enacted any meaningful telecommunications policy legislation (outside of broadcasting and cable) despite several opportunities to do so. Enacting legislation, as opposed to merely promising and/or threatening to do so, apparently does not maximize Congressional utility. Resolving issues through legislation would reduce long-term opportunities for generating decision-making rents by, for example, reducing the incentive of interest groups to deliver further electoral support (i.e., campaign contributions, votes, etc.). Reforming public policies too quickly (or at all) can fail to maximize the present value of decision-making rents.

Regulatory reform in the interstate toll services market illustrates both the process and the incoherence of U.S. telecommunications policy.

Limited competition (i.e., allowing large users to build private microwave facilities) was introduced in 1959 in response to pressure brought by large corporations. This policy subsequently was

712

broadened to encompass private carriers (like MCI) that sought to provide common carrier services. Nevertheless, full and free competition continued to be viewed as a second-best alternative to comprehensive regulation.

In the 1960s, Congress persuaded the FCC to begin regulating AT&T's interstate operations and pricing more closely, ostensibly for the purpose of reducing prices. To this end, the FCC saw limited competition in long-haul services to be a useful regulatory tool. Economist William Melody (then a consultant to the FCC) presented the idea this way:

> The Commission could encourage the entry of new common carriers into submarkets the new carriers could supply efficiently... By following such a policy, the Commission would be using the market force of competition as a regulatory tool in the prevention of monopolistic price discrimination.[3]

Competition also was seen to be a means for checking AT&T's political power. As reported by author Steve Coll:

> ... MCI was unleashed, nurtured, protected, and defended by the FCC and Justice because, in the words of [former FCC Common Carrier Bureau chief] Hinchman's predecessor Bernie Strassburg, "AT&T was getting so big, so fast." Competition was a means for the government lawyers and bureaucrats to wrest power away from AT&T, to regain control over the phone company. Judge Greene, a former government lawyer himself, indicated clearly ... that it was AT&T's size and power that troubled him above all.[4]

Economists and policy consultants have tended to mis-interpret these policy changes in hindsight by viewing the introduction of competition as an intentional and benevolent movement toward economic efficiency and social welfare maximization. Economist Roger Noll, for example, has commented that:

> Astonishingly enough, economics played a central role in changing federal telecommunications policy, as acknowledged by Philip Verveer, the lawyer who developed the antitrust case against AT&T, the Chief of the FCC's Cable Television Bureau when cable was deregulated, and the Chief of the Common Carrier Bureau when the FCC formally adopted the policy of minimizing federal regulation of telecommunications. The intellectual foundation of these policies is an economic case that the industry will be more efficient if it is minimally regulated and maximally competitive.[5]

Although these policy choices clearly were consistent with economic theory, it was political considerations rather than social efficiency goals were the driving force. It is not surprising, therefore, to see that the remedies proposed by the government in its antitrust action against AT&T were viewed by many economists as being inconsistent with sound public policy. For example, economist Lester Thurow argued that:

> Technological advances will from time to time require changes in the rules of industrial competition. With the development of microwaves and satellites, the long distance transmission of messages may have changed from a natural monopoly to a potentially competitive industry. If so, rules and regulation governing the telephone business should be changed to reflect this development. Whatever should be done, however, the correct answer is not an antitrust suit against AT&T. A regulated monopoly should be governed by regulatory procedures and not by antitrust procedures. If the goal is a competitive industry in long distance transmission, an antitrust case is simply not the means for getting to this objective. Deregulation is best achieved by deregulation, not by a lengthy court case based on principles that have noting to do with regulation and deregulation.[6]

A Justice Department consultant similarly questioned the remedies being pursued by the government:

> Taking an action (such as divestiture) is certainly not free. It imposes substantial legal costs on both sides and substantial managerial burdens for implementation. Insofar as industries are moving in the "right" direction, it may be more economical to allow them to do so than to impose significant changes through government actions.[7]

In the end, however, policy choices governing industry and regulatory structure were made according to the preferences of the Justice Department's antitrust chief and the presiding judge. Author Steve Coll summarized the outcome this way:

> Certainly it is true that the government lawyers and bureaucrats at Justice and the FCC were not driven to break up the phone company by any clear, coherent vision about how a decentralized telecommunications system would work better than the existing one. The Justice lawyers, for example, never seriously believed that the operating companies would ever be divested, and until it became a necessity as the case was about to go to trial, they spent very little time drawing up plans for how the nation's phone network would be managed if they won their case. Instead, the government lawyers were driven by the conviction that AT&T was "unregulatable," as Walter Hinchman, the [FCC's] former Common Carrier chief, always put it.[8]

As the government's case against AT&T was being resolved, another federal judge sitting just a few doors down the hall was hearing a virtually identical antitrust action that had been filed against AT&T by (now) Sprint, a long distance competitor. To the surprise of many, this judge decided all issues in AT&T's favor and dismissed Sprint's claim. It seems fair to conclude that many important telecommunications policy issues

were determined more by the luck of the judicial draw than by abstract notions of economics.

The incoherence of U.S. telecommunications regulation has continued under the Modification of Final Judgement (MFJ) decree that settled the government's antitrust case against AT&T. Under the terms of the MFJ, the Regional Bell Operating Companies (RBOC) were prohibited (among other things) from providing information services and from manufacturing telecommunications equipment. These two restrictions subsequently became the subject of intense debate.
After protracted litigation, the "information services" restriction was abandoned. So determined was the MFJ court to keep this restriction in place (even in the absence of a supporting evidentiary record) that the Federal Court of Appeals eventually reprimanded the lower court for abusing its discretion in the matter.

The "manufacturing" restriction continues in effect. Legislation was offered in the Senate in 1991 that would allow RBOC entry into this line of business subject to a "domestic content" requirement. This requirement is both irrelevant and contrary to rational telecommunications policy. It is, however, perfectly consistent with the private interests of trade unions, domestic competitors, and trade-bashers. Although this legislation was not enacted, the episode tends to confirm another conclusion of Public Choice theory: public policies not only can be co-opted over time by interest groups (as predicted by the "economic" theory of regulation), but also can be hijacked at their inception.[9]

4.0 INTERNATIONAL TELECOMMUNICATIONS POLICY

Despite its incoherence, the evolution of telecommunications policy in the United States has demonstrated that reduced regulatory oversight, deregulation, and competitive supply can combine to yield positive economic benefits. These results might be expected to provide guidance and encouragement to foreign administrations that are pursuing privatization and regulatory reform programs of their own. The theory of this paper suggests that reforms abroad will occur more swiftly and with less incoherence than in the United States where policy reform has taken more than twenty years. On the other hand, beneficial reforms will not be adopted either automatically or immediately.

The prediction that reform will occur more quickly abroad than it did in the United States is based upon the fact that technology and competition are in a more advanced state today than they were when reform began in the United States. These forces are judged to be sufficiently strong to overcome two other factors that might facilitate political rent-seeking: (i) foreign jurisdictions have centralized, ministerial control over telecommunications and, hence, need not contend with the overlapping authority of numerous legislative, administrative, and judicial bodies; and (ii) foreign jurisdictions are not hindered by the existence of multiple firms functioning as quasi-independent PTTs.

Although market pressures are strong and growing stronger, reform is unlikely to occur as rapidly as might at first be expected. Witness, for example, the continued reluctance of decision-makers to reform even the most egregious policy distortions: (i) a $10 billion disparity between revenues and costs for international telephone traffic; (ii) monopolization and cartelization of international satellite services; and (iii) restrictions against the resale and sharing of domestic and international leased lines.

Foreign administrations obviously desire to protect the financial integrity of their telecommunications operations, and international service tends to be the single most profitable area of operations. High prices on originating international traffic, plus high accounting (settlement) rates for terminating traffic, generate substantial funds with which to subsidize domestic telephone services and a variety of other government services and programs; e.g., postal services and domestic computer industries. The funds available for these purposes have grown appreciably over time, essentially for three reasons: (i) facilities costs have fallen with the advance of technology; (ii) prices have remained rigidly high because of regulation and cartelization; and (iii) competitive supply and private network usage have been restricted.

Moreover, international settlement practices generate hard currency flows from the pockets of foreign nationals, especially those in the United States where the volume of originating international traffic greatly exceeds terminating volume. In addition, the asymmetry between the competitive U.S. market structure and the monopoly PTT structure allows foreign administrations to capture a portion of U.S. productivity gains by "whipsawing" competing carriers, especially through return traffic arrangements.[10]

The nature, breadth, and depth of domestic subsidies make existing policies resistant to change. Only a foolish or naive political administration would voluntarily replace such hidden taxes with explicit charges to be paid by its own citizens. The reduction or elimination of these subsidies not only would serve to dissipate accrued political capital, but also would reduce rent-seeking opportunities by reducing the amounts available for redistribution among competing interest groups.

Regulatory policies can be expected to change in step with changes in the private utility functions of decision-makers. As discussed below, pressure for change is coming from three directions: (i) changing macroeconomic perspectives; (ii) technological and market forces; and, especially in Western Europe, (iii) political re-structuring.

4.1 MACROECONOMIC PERSPECTIVES

The collapse of Eastern European economies under centralized economic management has shown that state ownership and administration of productive

resources neither creates operating efficiencies nor improves upon market processes as a means for distributing and allocating resources. This development augurs well for regulatory change, and undoubtedly has contributed to privatization and regulatory reform programs in several countries.

On the other hand, these programs so far have created only limited competition, especially for switched voice services. Privatized firms typically have retained monopoly service franchises that in some cases are written into the state constitution. Thus, privatization does not necessarily signify a fundamentally more liberal telecommunications policy.

Governments not only recognize that private ownership of telecommunications resources produces a larger economic product, but also recognize that this larger product can be redistributed for political gain via regulation. Accordingly, privatization and regulatory reform programs might represent nothing more than a plan to: (i) raise funds by selling off public assets; and (ii) use regulation to effect (or perpetuate) rent-seeking policy choices. The political fiddles needed to effect a plan of this sort are readily accommodated through the judicious use of such tenuous assertions as these: (i) the state must continue to formulate and coordinate industry policy; (ii) the state must prevent privatization and competition from destroying the existing telecommunications infrastructure; (iii) only the state can represent the country's telecommunications interests in the world economy; and (iv) scale and specialization economies exceed the benefits of unlimited competition and user choice in any event.[11]

4.2 MARKET FORCES

Fortunately for telecommunications users and suppliers, market forces will erode the opportunity for decision-makers to generate rents through restrictive regulatory policies. As communications-intensive information and service industries contribute an increasing share of a country's national economic product, aggregate telecommunications expenditures will increase. As this occurs, the ability of domestic products and services to be competitive in a world economy will depend critically upon rational regulatory policies. Technological developments will generate further pressure by making restrictive policies increasingly difficult to administer, and by creating new opportunities for users to end-run regulatory constraints; e.g., by routing traffic through countries that have more rational policies.

4.3 POLITICAL RE-STRUCTURING

Economic union in Western Europe will not affect domestic telecommunications policies directly. However, its spill-over effects clearly will put pressure on domestic regulatory policies as national boundaries and markets become subject to wider and more intense competition.

One important consequence of economic union is that firms can locate in countries offering the most favorable regulatory climate. This promise of foreign direct investment carries with it an implicit demand for services that are comparable to those available in other (e.g., home) countries. Conversely, firms that locate (or remain) in countries with less advantageous regulatory policies will find it easy and profitable to circumvent restrictive regulation; e.g., by routing traffic through telecommunications-friendly countries.

Spill-over effects also will serve to erode domestic telecommunications monopolies and, with that, the capacity of domestic markets to support rent-seeking. The beneficial effects of this erosion initially will be greatest for large-scale business users that have both political clout and the ability to substitute between alternative technologies (e.g., to substitute leased lines for direct-dial service). Residential users will realize fewer (if any) direct benefits in the short term for at least three reasons: (i) these users will remain captives of the local service monopoly; (ii) monopoly structure facilitates rent-seeking; and (iii) competition in other sectors of the industry will reduce the funds available for subsidizing local exchange operations, thus creating upward pressure on exchange rates. In the longer term, however, market forces will tend to displace policy distortions, and an efficient array of services and prices will emerge.

5.0 SUMMARY AND CONCLUSIONS

Regulation -- whether by administrative agency, legislation, or judicial decree -- represents the power of the state to redistribute public and private wealth among competing interests. It is always in the self-interest of decision-makers to wield this power in ways that increase their personal utility, whether utility is measured in pecuniary terms (re-election or re-appointment, future employment opportunities, side payments, etc.), or in terms of the private satisfaction and self-esteem that come from shaping policies and events according to personal preferences. This self-interest tends to produce mindless and incoherent public policies that serve the public interest only by coincidence. Policy reform proposals that fail to take into account the self-interest of decision-makers are short sighted and stand little chance of being adopted.

The incentive for decision-makers to seek rents, coupled with the limited information about market demand characteristic and economic costs that is available to regulators, make the "public interest" theory of regulation a fiction. Other conventional theories of regulation are best viewed as being normative and descriptive explanations of the regulatory process rather than positive and predictive theories of policy choice.

Despite its incoherence, policy reforms in the United States have been beneficial on the whole and, consequently, might be expected to serve as a beacon of encouragement to other countries. However, the same pressures and incentives that

have shaped policy change in the United States also operate elsewhere in the world. It is wrong, therefore, to conclude a priori that socially beneficial reforms will be adopted immediately and in full by foreign administrations. Rather, policy change will occur over time as an artifact of the tension between political rent-seeking incentives and the unrelenting pressure of technology and market forces. The advanced state of telecommunications technology and competition extant in the world today, suggests on balance that regulatory reform will occur more quickly and with less incoherence abroad than it did in the United States.

NOTES

1. In 1987, the National Telecommunications and Information Agency (NTIA) estimated the annual direct cost of telephone regulation in the U.S. to be $8 to $10 per local exchange line, about $2 of which was attributable to federal regulation. NTIA also estimated the indirect, "deadweight" economic losses from the interstate toll-to-local subsidy to be about $1.6 billion annually. Wharton Econometrics estimated in 1986 that the indirect cost of the interstate toll-to-local subsidy was about $50 billion in foregone GNP growth and 77,000 to 111,000 new jobs foregone between 1984 and 1991, in addition to adverse consequences for state and federal tax revenues and the U.S. trade balance.

2. More generally, a "rent" is a windfall gain that accrues to the owners of resources that are especially scarce. An example is the price premiums that are collected by monopoly suppliers.

Regulatory Issues in the Communication Policy of Hong Kong: Setting New Rules of Game for Broadcasting & Telecommunication

Paul S.N. Lee, Ph.D.
Department of Journalism & Communication
Chinese University of Hong Kong
Hong Kong

1. ABSTRACT

With the worldwide trend of deregulation, emergence and convergence of new communication technologies and the run-up to 1997 when China resumes Hong Kong's sovereignty, the policy-makers in Hong Kong face a new communication environment with new players. The conventional wisdom of "positive non-interventionism" needs to be replaced by "forward planning" in communication policy to meet the new challenges posed by the new environment.

2. INTRODUCTION

Despite the fact that Hong Kong government does intervene in some sectors of the society, such as providing low-cost housing for the poor, packing the Hong Kong dollar with the U.S. after the nearly disastrous fall of it in 1983 due to political turmoil and the takeover of several private commercial banks on the brink of bankruptcy in 1983-84, the Hong Kong government to a very large extent holds an attitude of non-intervention in public policy. Government ownership of goods and services in Hong Kong is limited to law and order, postal services, the supply of water, and airport services. All other major public services such as electricity, gas, transport, telephone, telegraph and television are in private hands. There is no foreign trade restriction, no foreign exchange control and no central banking system. "Positive non-interventionism" is the term used by the government to describe its public policy.

A journalist attributes this non-interventionism to the inability of the government in helping the people after the Second World War. The government then could provide only rice and sympathy.[1] No matter what reasons are really behind the non-interventionist attitude, the government has relied heavily on private initiatives in providing communication services to the colony.

Hong Kong's first telegraph was set up in 1863 by Jardine, Matheson & Co and the first international telegraph to China was introduced by the Great Northern Telegraph Company in 1870. In 1877, the wonder of telephone was demonstrated by an interested civil servant, but he failed to impress the governor. Hong Kong had to wait for four more years to have the a telephone system. It was not until 1925 had Hong Kong a widely available telephone service. Marconi suggested twice to set up an Imperial Wireless Link including Hong Kong, one in 1910 and one in 1919, but Hong Kong did not have the service until 1925 because of repeated objection from the Admiralty in Britain.[2]

The reliance on private initiatives is also observed in the area of broadcasting. The formal inauguration in June 1928 of the first radio ZBW, which today called Radio TV Hong Kong (RTHK), was a result of the expatriates' enthusiastic quest for radio broadcasting.[3] The non-interventionist approach to communication was carried into the post-war era until 1990 when the policy makers were awakened to the need of the time to have more forward planning.

3. COMMUNICATION POLICY AFTER THE SECOND WORLD WAR

3.1 CHARACTERISTICS OF POST-WAR COMMUNICATION POLICY-MAKING

In the period after the Second World War, Hong Kong's communication policy exhibited four basic characteristics. They are "Act after problems arise", "Look for reference from abroad", "Wait for suggestions from private sectors" and "Trust the work to ad-hoc working parties". All these characteristics are typical of a non-interventionist government.

3.2 ACT AFTER PROBLEMS ARISE

This characteristic can be seen in many cases. In 1964, for example, due to increased population

and continued economic growth, the demand for telephone exceeded the telephone company's capacity to serve. It had a wait list of 34,000 applications and resulted in a black market for it.[4] One reason for such a lag behind the demand was bureaucratic red tape in granting new sites for more telephone exchanges.[5]

A more important reason was that the company's return on capital had declined from 14.3% in 1956 to 6.9% in 1963. Although the company's profit increased by 130% during the period 1956-1963, the capital which had to be invested increased by almost 300%. In other words, the incentive for the company to increase its services became negative. It is only after seven years when the public outcry against the poor service of the telephone company had reached an unprecedented pitch, the government proposed to amend the Telephone Ordinance to let the company to levy charges adequate to provide a return which could attract sufficient long-term private capital into the enterprise.[6]

In the area of broadcasting, an example showing the style of "Acting Afterwards" is the introduction of commercial broadcasting in 1956. Commercial radio was introduced not because the Administration wanted to instil more competition, nor did it have any great design for the role of commercial broadcasting. Commercialization of broadcasting was suggested because the government station, RHK, faced financial problems. The licence fees collected were insufficient to finance its growth. The original intent of the government was to introduce commercials in the programmes of Radio Hong Kong only. It hoped to bridge the gap between expenditure and revenue on the government station.[7]

But an amendment was made by M.W. Lo during the Legislative debate to introduce a separate commercial radio instead of commercializing some programmes of the government station. This amendment was agreed unanimously.[8] It was a very significant deviation from the original idea. A separate commercial radio would mean competition in wireless broadcasting and the maintenance of the tradition of public broadcasting. This outcome was quite interesting as it indicated that the plan formulated by the Executive was far from mature on the one hand, the legislature could have significant input in changing the policy on the other.

3.3 LOOK FOR REFERENCE FROM ABROAD

To look for reference from abroad was another feature of policy making in Hong Kong. In the United Kingdom, since the Conservative Party took power in 1979, privatization and deregulation have been the trend. After 1981, Britain introduced a series of measures to encourage competition in telecommunication. The Mercury was allowed to compete with the British Telecom in all sorts of network services. Customer premises equipment (CPE) and value-added network services (VANS) were open for competition. Cellular telephone was introduced 1985; four licences for cordless telephone (CT2) were issued in 1988 and three corporations were selected in 1989 to develop personal communications network (PCN).

All these developments in the U.K. were closely followed by Hong Kong. There are currently three mobile radio operators, four CT2 licencees (in Hong Kong it is called telepoint) and 17 paging licencees in Hong Kong. It is estimated that in 1991 the number of cellular telephones had reached 140,000.[9] At present, only telephone and international data services are still being monopolized because of the exclusive franchises for both will expire in 1995 and 2006. Both franchises are held by the Hong Kong Telecommunication International which was formed after the successful takeover of the Hong Kong Telephone Company by the Cable & Wireless Hong Kong in 1988.

In the case of television, reference was drawn heavily from abroad. When the Television Bill was introduced in 1964, the Colonial Secretary made it clear that the bill owed to similar legislation in Australia. A major feature of the Bill was to prevent foreign control of TV service and to limit cross-media ownership. It stipulated that not less than 60% of the voting shares of the franchised company should be owned by British subjects ordinarily resident in Hong Kong, and that voting shares owned by any non-British person or organization be restricted to 15% or less of the total. In addition, no competitor, supplier of broadcasting material or advertising agent may have a controlling interest in such company.[10]

Yet the underlying principles and means for carrying out these provisions in the context of Hong Kong were not worked out satisfactorily. In the second reading of the Bill several months later in 1964, the clause for restricting foreign control was struck out because "there might be such a risk if unduly onerous restrictions on shareholding

and share transfers made investment in the undertaking unattractive. ..... the public would not receive the standard of television which the Bill seeks to provide".[11]

In 1965, the Television Bill was amended again to make provision for the Governor to allow existing TV service provider i.e. Rediffusion wired TV service to get the franchise of wireless TV. It is interesting to note that in the amended bill, the provision against cross-media ownership was not struck out; instead, it was made to be "effective" only after the grant of the licence for wireless TV. This amendment was claimed to give the Governor "complete freedom to select the best and most suitable applicant".[12]

From the above, we can see that the policy making process in Hong Kong is always on an imitative basis with piecemeal amendments to suit the real situation. Despite the concern of cross-media ownership in the TV Bill 1964, up the present, Hong Kong still has no comprehensive legislation against cross-media ownership. With the emergence of more new media services, growth of capitalism and convergence of communication technologies, cross-media ownership will become a thorny issue in the years to come.

3.4 WAIT FOR SUGGESTIONS FROM PRIVATE SECTORS

Another characteristic of communication policy making in Hong Kong is to wait for private initiatives. The government only occasionally initiates new measures or services. In 1964 when the Telephone Company's service deteriorated to an intolerable level, it was the company itself to suggest for the improvement of service accompanied with an increase in charges. The general practice of the government is to act upon the suggestions, making adjustment and compromise. When the telephone company requested to raise the charges in 1963 to afford a return of 10% on capital employed, the Financial Secretary referred to the 8% of similar undertakings in the U.K. and the 7% of the American Telephone & Telegraphy Company in the U.S., and finally settled with 9% for the Hong Kong Telephone Company. The rate was claimed to be "related to conditions in Hong Kong".[13]

In 1957, the government indicated that wireless TV was not considered because of technical difficulties, but three years later in 1960, the government set up a working party to consider the development of television in view of the enthusiastic business interest in commercial wireless TV.[14] Such a "wait-for-proposal" practice prevailed up to 1990. When the satellite TV suddenly emerged in Hong Kong, it was the company making most of the suggestions as regards how it could be regulated in order to avoid the infringement of the cable franchise. In waiting for suggestions from private sectors, the government often loses its initiating influence, reacting passively to pressures exerted by business interests.

3.5 TRUST THE WORK TO THE AD-HOC WORKING PARTIES

In the past several decades, Hong Kong government did make some initiatives in the areas of telecommunication and broadcasting. Yet, most of the time, it relied on recommendations from ad-hoc working parties, which might or might not be composed of people with expertise in the issues concerned. In recent years, when confronted with highly technical issue, the government hired consultancy companies to do the job. For example, the Booz Allen & Hamilton was commissioned twice to examine the telecommunication situation in Hong Kong in 1987 and 1990.

The use of ad-hoc working groups is most obvious in the broadcasting field. It is almost an established practice of the government to appoint a working party to review the existing situation and provide recommendations as regards the renewal of the licence and related matters when a broadcasting licence is going to expire. For instance, when the 25-year licence of the Rediffusion's Wired Sound Service was due to expire in 1973, a working party was formed in 1970 to examine the future of broadcasting. When the licences for the wireless TV and commercial radio were going to expire in 1988 and 1989, a Broadcasting Review Board (BRB) was formed in 1984 to review the broadcasting situations and make recommendations on broadcasting policies. The advices of these two ad-hoc working groups have had tremendous influence on the development of broadcasting in Hong Kong.

The obvious disadvantage of relying on recommendations of ad-hoc working parties is the failure to keep track with changes in broadcasting, especially in a rapidly changing situation. For instance, the Working Party on the Future of Broadcasting 1971 recommended a tripartite system in commercial wireless TV i.e. to have

three competitors. In 1975, the third wireless TV, Commercial TV Ltd. (CTV) went into operation with heavy emphasis on instructional television which was conceived as a main reason for its existence by the Working Party. But three years later, it wound up because of heavy financial loss. After the demise of the CTV, an investigation was done with the conclusion that the market could not support three operators. Since then, no initiative has been made to re-examine the viability of a third commercial TV operator. In the BRB Report 1985, the idea was also passed lightly. It probably has to wait until the appointment of a next working party to have a chance for review.

The abolition of wired TV service in 1973 on the recommendation of the 1971 Working Party also left the pay-TV market untouched for more than 15 years. Until the idea of cable TV was proposed by the Broadcasting Review Board in 1985, nothing was seen as regards the possibility of tapping the pay-TV market. And the full idea of Pay-TV service was in fact picked up by the government only after the demise of the Cable project in 1990. Before it, the government had only an idea of "cable TV" which could rely on subscription and small amount of advertising. The possibility of tapping the pay-TV market by other means of technologies was not thought of before 1990.

3.6 INADEQUACY OF CONVENTIONAL STRATEGIES

In a way, these features in policy making are not necessarily bad since dealing with problems only when they are there would save misguided resources and waiting for proposals from private sectors would ensure that the services suggested are in demand and the business would be viable. To look for reference from abroad and consult specialist ad-hoc working parties is also desirable and better than working behind close door. The only problem is the delay in delivery or improvement of services. In a relatively isolated society with modest growth in demand for new services, such a policy orientation does not seem to be very unsatisfactory. After all, Hong Kong has become one of the most prosperous city equipped with modern telecommunication and broadcasting services since the Second World War.

But the question in the 90s is whether such a non-interventionist strategy can still render satisfactory communication service and keep Hong Kong abreast of the latest world development in communication, enabling her to keep her enviable economic and financial position in the world. From what had happened in cable TV and the second telecommunication network, it does not seem the non-interventionist strategy could continue to serve Hong Kong well. This is largely due to crucial changes in the communication environment since the 1980s. These changes of environment are due to three factors. They are first the worldwide deregulatory trend; second, the rapid development and convergence of communication technologies; and third, the imminent change of Hong Kong's sovereignty in 1997.

4. CHANGE OF TIME

4.1 WORLDWIDE DEREGULATORY TREND

The worldwide deregulatory trend was set by the U.S. In 1982, the AT&T's local telephone and telecommunication services were separated from the company. Its international services were also open for competition. In the area of broadcasting, almost all the regulations on cable TV were lifted in the early 1980s, leaving the regulatory work to local municipal authorities which conclude the franchise with the cable TV company. It resulted in tremendous growth for cable TV. In 1980, cable TV had a penetration rate of only 23% in the U.S., in 1990 the figure was 55%.[15]

Western European nations followed the step of the U.S. Britain went the farthest and deregulated nearly all its telecommunication and broadcasting services. The British Telecom and the Mercury are now competing in all aspects of telecom services, more than 20 exclusive regional cable TV licences were issued in the last ten years and a satellite TV service was introduced in 1989, which however had to merge with Murdoch's Sky Channel in 1990 due to financial difficulties. France and West Germany also deregulated their communication services in the 1980s. The laws of mid-1990 in Germany swept almost all restrictions in satellite communications and television. It has overtaken Britain which was the first European nation to introduce satellite liberalization.

What has happened in the advanced industrial world and particularly in the U.K. could not be passed lightly by Hong Kong which is a British colony well-integrated into the world capitalistic economy. The worldwide deregulatory trend subjects Hong Kong to pressure to liberalize its own services. Before the 1980s, demand from local or foreign interests to enter the traditionally monopolistic field of telecommunication and to offer new broadcasting services was small. In the

80s and 90s, the mood has changed to let new entrants join the game. "Over-protection" of conventional players is an unforgivable bureaucratic mistake in the 90s.

4.2 RAPID DEVELOPMENT & CONVERGENCE OF COMMUNICATION TECHNOLOGIES

In the 80s, communication technologies have developed at a quick pace and shown a tendency of convergence. Conventionally, broadcasting services are clearly separated from telecommunication as well as from print services. Radio and TV used to be regulated neatly by focusing mainly on their content, whereas telecommunication services were mainly regulated in respect of its technical standard. The message communicated over the telecom network or radio wave is largely a private matter of the users. Nevertheless, with the emergence of satellite TV, for example, such a distinction between broadcasting and telecommunication becomes blurred. Since satellite signals can become images and are widely receivable through Satellite Master Antenna, satellite communication can provide telecommunication as well as broadcasting services. The regulation is even more problematic if the uplink of the satellite signals is made in other countries.

In the case of video-cassettes, it is generally regulated as a print medium. It is not a "broadcasting" service although it is viewed on TV screen. But the pornography in video form, for example, has made video-cassettes distinctively different from the print medium. Similarly, computer porn and value-added services on telephone are no longer a purely telecommunication service although they utilize the telecom network. Hong Kong is facing these regulatory problems arising from the convergence of communication technologies and services.

Apart from regulatory problems, the rapid development and convergence of communication technologies also make the investment in new broadcasting or telecommunication services costly. For example, the defunct cable project of Hong Kong was estimated to involve an investment of HK$ 7 billion (U.S$ 0.9 billion). Even without laying a fibre optic network, just using the technologies of microwave to replace the horizontal trunk lines would still involve an investment of U.S.$ 0.38 billion.

Such a large scale investment in providing new services with new technologies makes the participation of big corporations necessary. The involvement of real big corporate giants in communication field is a new factor in the 90s. These big giants usually have had much influence in government or market, local or foreign. This setting puts the government in a difficult position when a big corporation tries to exclude the other to gain most of the advantages for itself. In the case of Hong Kong, the number of big corporations which can afford heavy investment in modern communications is small. The flex of muscle among the few big corporations in fighting for their best interest could drive the government into a corner.

4.3 CHANGE OF SOVEREIGNTY IN 1997

In 1997 Hong Kong's sovereignty will be reverted to China. Such a power shift has made the communication environment different from before in three respects. First, the uncertainty in future has made large investors hesitant in putting too much stake in Hong Kong. The political uncertainty has deprived Hong Kong of its opportunity of having more investors in large scale communication projects. This situation makes the few interested big corporations in Hong Kong more influential in the policy making process.

Second, the gradual fade-out of the British political influence in Hong Kong has reduced the authority of Hong Kong government, subjecting it to constant criticism from the corporations, the press and the general public. Before the 80s, the government decision was seldom challenged because of its capability in ignoring business pressure and public opinion. The colonial government since the late 80s has to take heed of criticism from private and public, otherwise its effective rule in the last few years may be jeopardized.

Third, the Chinese communists keep close watch on the development in Hong Kong before the transition of 1997. At the end of 1991, during a deadlock in negotiation between China and Hong Kong over the expenditure on the construction of a new airport, the Chinese government made it clear that all infrastructures and major affairs in Hong Kong crossing 1997 must have the opinions of China. This obviously includes telecommunication and broadcasting. In fact, the Chinese government protested against the granting of a 12-year franchise of Metropolitan Broadcasting to operate a second commercial

radio in 1991.

In telecommunication, the Chinese already exerted its control through its purchase of 20% shares of the only existing network of Hong Kong Telecom International in early 1989. After the demise in 1990 of the cable project which originally included a second telecommunication network and cable TV service, no decision regarding the tender for the second network is made up to this moment. The second Booz Allen & Hamilton study was finished a long time, problems in negotiating with China for a second network is probably one reason for the delay. The China factor affects the government policy process in two ways. One is to increase the political work in dealing with China. Second is to affect the participation and realignment of the big corporations, which will also need the goodwill of China, to conduct new services in broadcasting and telecommunication.

5. PROBLEMS ARISING FROM CHANGES OF TIME

5.1 DEREGULATION OF TELEPHONE & INTERNATIONAL DATA SERVICES

In 1988 when the government called tender for the second telecommunication network and cable TV service, it was stated clearly that the second network could provide all non-franchised services. As regards the franchised telephone and international data services, many bidders said they got the "impression" that competition would be allowed in a short time. But after the bid, the government did not make any clear commitment for the liberalization of telephone and international data services despite that fact that it was widely known that the first Booz Allen & Hamilton Report in 1988 recommended the end of the monopoly.

While the franchise winner, Hong Kong Cable Communications (HKCC) was hesitant of proceeding with the project, AsiaSat I was launched in April 1990 opening an opportunity for satellite television. The Hutchison Whampoa Ltd. lost no time in proposing to the government in July to launch a regional satellite TV service. The HKCC objected to such a proposal vehemently claiming that the satellite service would cream-skim its cable TV profits. Meanwhile, internal conflicts among the shareholders of the cable company became serious. At last, the HKCC quitted the cable project.

Probably, only the few people involved in the decision of setting up the second network know what had really happened to the indecision about the end of telephone and international data monopoly in Hong Kong. Without the services of telephone and international data communication, the heavy investment in a second network can hardly be justified. This is even more so in the context of political uncertainty due to 1997.

5.2 COMPATIBILITY BETWEEN CABLE AND SATELLITE TV

By the time when cable TV was proposed in the BRB Report of 1985, satellite television was something seemingly very remote. Nothing was mentioned in the report about such a possibility. Finally, when it emerged in 1990, the policy makers were caught in a dilemma. On the one hand, it had awarded an exclusive franchise to the cable company to run a subscription service, on the other hand, it wanted to keep the satellite service which threatened to move its base to somewhere else, which would cause embarrassment to the government. The cable company however insisted that both services were incompatible in Hong Kong and the satellite service infringed its exclusive right in providing subscription service. Finally, the government was torn between the two big corporations and forced by circumstances to make a compromising solution. Satellite TV was to stay but without local subscription, local advertising and Cantonese programming at least in the first three years. Unfortunately, the cable company still quitted the project for reasons other than the introduction of satellite TV.

The demise of cable TV and the second telecommunication network indicate very well that a clear plan for non-franchised telecom and cable services vis-a-vis franchised telecom services and other TV services is needed. The demise of the cable project also indicates that the reliance on recommendations from ad-hoc working parties might lag behind in a rapidly changing communication scene; it was only five years from 1985 to 1990, but communication technologies had already changed greatly.

5.3 REGULATION OF SATELLITE TV

Ever since the introduction of satellite TV service, the company has never stopped pushing the government for lifting the ban on Cantonese programming and local subscription. Now that the cable company is gone, the only opposition in the

industry is raised by the dominant wireless TV company Television Broadcasts Ltd. (TVB). TVB launched a publicity campaign in November 1991, releasing its own paper on the future of TV industry in Hong Kong, aiming at applying pressure on the government. It claimed that if the ban on local language programming is lifted, the satellite service will become a de facto wireless TV undercutting its audience and advertising revenue. They press for an early review of their licence which will expire in 2000, demanding the change of royalty structure and other conditions.

On the other hand, the satellite service launches constant attack on the "unreasonable" restriction on a local company from programming in local language, although it was a suggestion they made to the government so as to avoid infringement of the exclusive franchise of the now defunct cable company. In view of the changes in the communication scene since the demise of the cable company, an overall review of the whole television broadcasting industry is urgently needed. Whether or not the government will be able to do this is questionable because such an exercise is usually done by an ad-hoc working party which will be appointed only occasionally. Even with the appointment of such a working party, it is still doubtful whether the recommendations will not be outdated by events in a short period of time.

Since 1989, policy branches have been formed to take care of policies relating to telecommunication and broadcasting. Whether these branches can carry out the jobs of the ad-hoc working parties on a regular basis remains to be seen, but the separation of these two areas into two different branches i.e. Economic Services Branch for telecom services and Culture & Recreation Branch for broadcasting, already created some difficulty in the consideration of options in providing subscription TV in Hong Kong.

The emergence of satellite TV also raises the issue of cross media ownership. In Hong Kong today there is nothing like the anti-trust law in the U.S.; nor is there regulation governing cross-media ownership except in television broadcasting. Since the satellite company is a subsidiary of Hutchison Whampoa which also have shares in the second commercial radio i.e. Metro Radio, and have subsidiaries operating cellular telephone, paging services and CT2, some people express concern about the possibility of anti-competitive behaviour by some giant corporations and the monopoly of opinions in media. Whether this issue will be considered in the future review is not known. It is better to take it up early than before it is too late.

5.4 POLITICAL ADVERTISING

In the run-up to the reversion of Hong Kong's sovereignty in 1997, a series of democratic reforms have been introduced by the colonial government in the 80s. In 1991, there was the first time direct election to 18 seats out of 60 in the Legislative Council. Accompanied with this political change is demand for political broadcasting. Under existing provisions, no political advertising is allowed on broadcast media, yet provision is also there for the governor in council to establish standards for the broadcasting of programmes containing political material.

In the 1985 BRB Report, nothing was mentioned about political programmes or advertising. No standards have ever been established regarding political programmes. During the election campaign in 1991, an issue arosef when the United Democrats of Hong Kong, the largest political democratic party, wanted to place a radio advertisement for a fund-raising concert. The issue was whether such an ad for fund-raising constituted political advertising which could be construed to mean only the promotion of the candidate or parties directly and explicitly. There was no explicit definition of the word "political". Finally, the ruling of the Broadcasting Authority was to define it broadly to include any messages that would directly or indirectly benefit the party or political candidate concerned. The United Democrats finally dropped the case although they intended to ask for a judicial review.

This incident again indicates insufficient forward planning. Some ways must be found to improve the policy process to anticipate and accommodate the changes of communication environment in Hong Kong.

6. SETTING NEW RULES OF GAME

6.1 FORMING PERMANENT POLICY-MAKING STRUCTURE

In view of the rapid changes in the communication environment, a permanent policy-making structure to monitor the continuous development and to plan ahead is urgently needed. This structure must comprise people with expert knowledge in the concerned areas. At present, the policy

branches dealing with telecommunication and broadcasting are headed by administrative officers with generalists' background, which is a tradition of the British civil service. Technical experts i.e. people of departmental grade who will not be transferred in and out of a department, are largely involved at the level of providing expert knowledge only, seldom are they directly involved in making the decision. Those who are responsible for making major decisions are usually administrative officers moving around different departments, handling a variety of related or unrelated subjects. Such an arrangement necessitates occasional appointment of working parties or hiring of consultancy service to study the broad issues of communication.

In order to meet the challenges of the time, the decision-making body of communication must be composed of people on a permanent basis with expert knowledge in economics, communication, engineering and law, in addition to people excelling in political bargaining and manoeuvre. They are not only responsible for making the decision, but monitoring the progress and making necessary adjustments. Most important of all, they should plan well ahead of the oncoming of new services and new communication technologies.

Forward planning by people with expertise on a long-term basis would also help to reduce the suspicion of China about the British intent in liberalizing the communication services in Hong Kong. Such a body can also deal more effectively with the industry which may mislead the policy-makers by manipulating technical information.

6.2 SETTING OUT PLANS TO ACCOMMODATE COMPETITORS

In the 90s, the new rule of game in telecommunication and broadcasting is to encourage competition. Development and experience in the past several decades indicate that the rationale for maintaining monopoly in communication services no longer stands. It has been found that communication monopolies in the advanced industrial countries are over-protected. The argument for maintaining economy of scale and scope in providing the best service does not seem to be sustainable in view of the fact that new entrants do make profits and the service rendered under competition is better than before. The idea that monopoly is necessary for the provision of universal service e.g. telephone, through cross-subsidization of unprofitable sector by profitable one may be valid in an underdeveloped economy. In the 90s, Hong Kong has developed into an advanced economy, the cross-subsidization argument cannot hold any more.

In the case of cable TV monopoly, the idea of cross-subsidizing some "desirable" services by lucrative services also proved to be impracticable since there were too many such money-losing services required on the operator. The role of public broadcasting is better served by a public broadcaster financed by public fund than by requiring commercial operators to play a full role of public broadcaster. Such a "full role" requirement would reduce the flexibility of the commercial operators, making them financially difficult even in the case of monopoly. The best rule seems to be one which lets the players decide how they are going to play in the market.

In retrospect, in the broadcasting history of Hong Kong, the two failure cases of television, i.e. Commercial TV Ltd. in 1978 and Hong Kong Cable Communications Ltd. in 1990 shared one common feature. It is the stringent requirement of them to play the role of a public broadcaster. In the case of CTV it was instructional TV; in the case of cable TV, it was the provision of a great variety of channels which served to look good in the tender, rather than to provide profitable entertainment services.

6.3 LAYING GROUND RULES FOR EQUAL FOOTING ONLY

This lesson brings us to another point in setting the new rules. Not only plans must be considered ahead in accommodating new competitors, government should limit itself to laying down ground rules for different players only. Always let the players fight out the result of the game is the best way in communication planning. Requiring the private sectors to do jobs which should be done by the government, e.g. public service broadcasting or cross-subsidizing the poor telecommunication users may result in failure or inefficiency of the services.

From past experience, a better way to set the new rules is simply to ensure free entry into the market. What the government should do is just to lay down ground rules for the competitors to stand on equal footing in the game. Then, let the players play. However, the government after preparing a level ground for all players should continue to monitor the game to ensure fair play on a long-term basis. In monitoring the game, some legislations in curbing anti-competitive

behaviours, which are absent now, are urgently needed. Without such legislations, the game can hardly be played successfully on a long-term basis.

7. CONCLUSION

In view of the changing communication environment, the government needs to improve its policy process by relying less on recommendations of ad-hoc working parties, taking more initiatives in making policy and planning ahead, anticipating and accommodating new players who are usually financial giants, refraining from granting monopolies in communication services, resisting the temptation of requiring private business to provide a substantial amount of public services which are the responsibility of the government, making new entry into the market and fair play a norm and after all, setting a permanent decision-making and monitoring body with relevant and adequate expertise.

EFFECTIVE REGULATORY PROCEDURES: THE FOUNDATION OF SUCCESSFUL TELECOMMUNICATIONS REFORM

Aileen A. Pisciotta
International Communications Counsel 1/
Latham & Watkins
Washington, D.C.

1. ABSTRACT

Successful privatization and regulatory reform in the telecommunications sector depends in large part upon the implementation of effective regulatory structures with the attributes of consistency, transparency and flexibility. This paper examines some of the fundamental aspects of new regulatory structures, including allocations of jurisdiction among governmental authorities, selection of appropriate organizational form, development of substantive expertise, arrangements for funding, and establishment of administrative procedures that ensure public access to decision making.

2. INTRODUCTION

Privatization and liberalization in telecommunications markets the Pacific as well as in all other regions of the world, are creating an urgent need for reform of telecommunications regulatory processes. Regulatory structures and procedures are at the gateway of new telecommunications services. The regulatory process, how it is organized and how it functions, is a critical element in assessing the actual or potential impact of telecommunications on national growth and regional integration. A poorly-structured regulatory system can paralyze telecommunications growth by impeding the development of substantive policies and eroding public confidence in the decision-making process. On the other hand, a well structured regulatory system will significantly enhance telecommunications development by ensuring that developments in the private sector are consistent with public goals and that the governmental decision-making does not unnecessarily constrain the innovation and efficiencies of private enterprise. Thus, an effective and efficient reguatory process is critical to the achievement of economic, technical, social and political objectives.

Successful creation of a new regulatory structure requires careful consideration of a number of fundamental issues, including identification of specific goals for the regulatory process, a well thought out organizational form for a regulatory entity with clear allocations of power and responsibility and, establishment of decision-making procedures to ensure the fairness of the regulatory process.

Each country necessarily will devise its own unique regulatory structure based upon the options available under existing law and the objectives that are intended to be achieved. However, there are certain common threads and fundamental principles that may usefully guide this difficult process. This paper is addressed primarily to those cases in which governmental regulation of private enterprise is a new phenomenon. It focuses on the critical areas of structural, jurisdictional, and procedural issues which must come into play in establishing an entirely new regulatory system.

3. FUNCTION OF THE REGULATORY PROCESS

3.1 Determination of the Role and Function of the Regulatory Agency

The very first set of issues to be addressed in structuring a regulatory system is identifying the desired role and function of the regulatory agency. In markets where one or more basic services operators have dominant market power,, there is a critical role for the government to play in ensuring subscibers that the dominant operators will provide adequate service at reasonable charges. In mixed markets containing elements of both monopoly and

726

competition, the need for a regulatory presence may be even more pronounced. The regulator identifies those segments of the market appropriate for competition and helps, through regulation of rates and rate structures as well as technical interconnection requirements, to establish market conditions that reduce barriers to entry.

In either case, a strong and effective regulatory presence is often a critical guide the the efficient introduction of competition, the consistent achievement of social goals as technology and services constantly change, and the oversight of relations with the national systems of other countries and multilateral organizations in international markets.

The role of the regulator in any particular market will be related, in large measure, to the existence and effectiveness of antimonopoly laws. In Venezuela, where there are no applicable antitrust laws, substantial attention was paid to the creation of an effective regulatory entity and system at the outset of the privatization process. In contrast, both New Zealand and Chile virtually eliminated regulatory functions at the time that their national telephone systems were privatized, placing substantial reliance on the then existing antitrust laws to ensure opportunities for competitive entry. However, in recognition of the fact that antitrust laws do not substitute for a forward-looking policy development process, Chile is now reexamining the issue of regulatory functions.

3.2 Organizational Objectives

The regulatory process becomes more complex and difficult as market relationships become more intricate. This is particularly true with the introduction of competition, which involves the licensing of multiple operators, allocations of scarce radio frequency spectrum for new services, and establishment of technical standards for interconnection of competitive networks. Nonetheless, it is critically important that decision-makers maintain the objective of ensuring that the regulatory process is efficient and avoids unnecessary impediments to the functioning of the marketplace. It should be an objective of the regulatory process to promote innovation and increasing reliance on market forces. Moreover, decision-makers should endeavor at every step and at every level to reduce to a minimum the varieties of approvals required for any market initiative, and to clarify and streamline regulatory procedures. In other words, it is crucial to reduce the incentives for "self aggrandizement" of the regulatory entity.

3.3 Substantive Goals

Any new regulatory system should have, at its foundation, the following three goals. The first goals is consistency. This is critical for public and investor confidence. The regulatory structure must be stable and should be guarded, to the extent possible, from arbitrary political change. While the regulatory process must be responsive, in a broad sense, to prevailing political mandates, the individuals entrusted with regulatory decision making must be relatively insulated from removal for purely political reasons. Additionally, the substantive decisions reached by the regulatory entity should be constrained, to some reasonable degree, by prior decisions. In other words, regulatory policies and the tools utilized to implement those policies must have some degree of consistency with the past.

The second goal is transparency. The regulatory process must be conducted openly and rationally. Insurance of transparency must involve some provisions for access by the public and regulated companies to information about the decision-making process. It also

requires the establishment of clear administrative procedures and penalties for failure to follow such procedures.

Finally, the regulatory process must have flexibility. While regulatory decision-makers cannot have unlimited discretion, they must be given wide latitude to adjust policies and requirements to changes in circumstances. Technology and services are changing constantly, as are customer requirements. The regulatory process must have built-in flexibility to adjust to these developments or it will become useless within a very short period of time.

4. STRUCTURAL ISSUES

4.1 Constitutional Context

Any effort to establish a new regulatory system within an existing government must begin with an evaluation of how the regulatory function fits within the existing constit ²θutional structure of the country. The first level of this inquiry is to assess the "horizontal" allocations of jurisdiction and authority at the central government level. These allocations will be different, depending upon the system of government and the laws existing in a particular country. For example, allocations of authority and options for a regulatory structure will vary substantially between an executive form of government under a common law system, such as the U.S., a parliamentary form of government under a common law system, such as the U.K. and an executive form of government with a civil law system, as prevails in much of Latin America and Europe. Even within the general framework of the combination of executive governmental systems, there are many variations of allocations of power and jurisdiction under individual country constitutions.

In addition to the "horizontal" allocation of responsibilities and powers at the central government level, the constitution will also establish "vertical" allocations between the central government and the regional or local governments. Under some constitutions, regional or local governments will not have any constitutional authority over public services such as telephone networks. Under others, local governments retain certain direct authority. Legal systems which require shared authority between the central and regional governments often result in complicated regulatory structures and difficult jurisdictional disputes. The dual state/federal regulatory system in the United States is a prime example of these potential complexities.

4.2 Organizational Form

Once a the decision has been made as to which branch of government has the constitutional power to establish a regulatory agency, the specific organizational form of the agency must be established. Sometimes, "organic" laws dictate specific organizational forms and restrict alternatives.

In addition to the fact that existing laws may constrain options for establishment of a new regulatory agency, in many countries, privatization and liberalization of telephone administrations require a multistep, transition. In countries that have never had privately-owned or operated telecommunications companies, the first step of the transition is to reorganize the state-operated PTT (Postal Telegraph and Telephone Administration). The operational functions of the PTT usually are placed in a new state-owned operating company, while the regulatory functions are removed to a ministry of communictions. Subsequently, a new regulatory agency may be established either inside or outside of the ministry. Also, the operational entity may be fully or partially privatized.

The selection of the appropriate organizational form for the new

regulatory entity requires a balancing of several different factors, including insulation from political change, responsiveness to social policy concerns, independence of judgment and reliability of sources of funding. If the regulatory function is to remain within the executive branch, one alternative may be the separation of communications from other infrastructure areas, such as the postal service or transportation, and the creation of a new ministry or department dedicated solely to communications. The advantage of this approach is that it provides very high level authority for issuance of communications policies. I also may permit the centralization of all communications issues (both telecommunications and mass media) in one administrative body. However, this approach has the disadvantage of adding a major new bureaucracy to the governmental structure. Also, as a ministry or department, it is not insulated from political change. Moreover, funding would normally be provided through the general treasury, with appropriations approved by the legislature. Thus, a purely executive branch structure is responsive to the policy directions and political directives of the administration in power, but may not have the necessary financial or political independence for the establishment of telecommunications policies on a consistent and stable basis.

As an alternative, a quasi-independent commission, agency or other authority may be established within or in connection with a ministry or department. Such a regulatory structure already has been established in a number of some Latin American countries, including Mexico and Venezuela. Under this approach, the telecommunications regulatory functions are separated out from other ministry activities. A separate head of the commission or agency is charged directly with responsibility for the regulatory function. This structure does minimize the tendency to create additional bureaucracy and does provide some independence of decision making, particularly if the head of the Commission or agency has a term of office that is independent from the term of office of the minister. However, this structure does not solve the problem of lack of insulation from political shifts, particularly if the minister has the authority to exercise full discretion to remove the head of the commission or agency. Also, under the subministry or departmental office approach, the issue of funding becomes critical. The subministry will have to secure a certain proportion of the general treasury allocations on a consistent basis. An additional advantage is that the subministry structure can normally be established by presidential decree, and does not require new legislation. Therefore, it can often be a good transition step to a more independent regulatory agency which may require establishment through a well thought out new statute.

Finally, there may be various forms of "independent" agencies which may be possible to implement in a particular country. Such a new entity may be modeled on either a new or existing form of government entity. Again, sometimes permissible governmental forms are constrained by specific provisions in the constitution or a governmental "organic" law. An independent entity most likely would be modeled on one of the following general types of forms: a controlling or enforcement entity, which may be part of either the legislative or executive branches of government, an independent commission which would function primarily as a policy setting organization, or an operating entity which would be a form of a state-owned enterprise authorized to impose fees and retain revenues. In all of these alternatives, the issues of selection and removal of leaders, and the insulation of such leaders from other political forces, become critical.

It is of paramount importance to ensure that the form of regulatory entity selected has the power and authority to carry out all of the varied responsibilities of the regulatory process. Regulatory activities include quasi-legislative functions of establishing regulations, quasi-executive functions of establishing overall policies as well as granting individual licenses, and quasi-judicial functions of resolving disputes and investigating malfeasance or failures of performance.

Moreover, it may not be necessary to settle on the form of an entity that has singular and exclusive responsibilities for telecommunications policy and administration. It may be that both the executive branch and the legislative branch will require some participation in the regulatory process. The executive branch inevitably will need to participate in the establishment of general policies and the president normally will want to maintain an administrative advisor on communications issues. Similarly, the legislature may also demand a regulatory agency responsive to its agenda and obligated to justify its expenditure of general treasury funds. It may be inevitable that the regulatory process that ultimately evolves includes at least a couple of different agencies or offices, all responsible for a slightly different aspect of the communications regulatory function. In common law systems, the judiciary will also play a key role in refining the justifiability of policies and the extent of legal authorities.

4.3 Special Issues of Power and Jurisdiction

In the telecommunications industry, there are several specific issues that require careful assignment of power and jurisdiction. Only two particular ones are mentioned here. The first is with respect to the radio frequency spectrum. Different portions of the spectrum will be used for public telecommunications services, private telecommunications services, mass media services and governmental operations. Ideally, the allocations for these uses should be closely coordinated. As technologies begin to merge and services become more integrated, it is particularly beneficial to have a single regulatory entity that has primary responsibility for all frequency allocations and license assignments for all non-governmental uses, including public and private telecommunications as well as mass media (broadcasting). The frequency allocations for government and non-government may be handled by different organizations, but should be closely coordinated. Some mechanism may need to be provided for resolution of disputes on frequency allocations between government and non-government interests. Such disputes often arise around national security issues. Ideally, the arbiter of any such disputes should not itself have any vested interest in frequency allocations (such as the military).

It is also important to establish clear responsibility for participation in international consortia and organizations. For example, the privately-owned public services provider may function as the signatory to Intelsat and Inmarsat. However, the regulatory entity should direct the participation of the signatory in the decision-making meetings of these international organizations. Moreover, the regulatory entity must direct the participation of delegations representing the government in the official meetings of the International Telecommunications Union. Other governmental agencies, including the foreign ministry, also may have a role in establishing national policies to be promoted in multilateral and bilateral international negotiations.

4.4 Composition of the Agency

After the basic form of the regulatory entity has been decided upon,

it will be necessary to consider the structure of the entity itself. As an initial matter, the size of the entity, (the commission, board, office, council, sub-ministry or whatever organizational form is selected), will be an important factor. An effective regulatory entity can be comprised of as few as one director with a small staff. In the United Kingdom, the Office of Telecommunications is organized in this way. Such a structure avoids unnecessary bureaucracy and may be highly efficient, particularly in markets characterized by monopoly or duopoly service providers with whom the regulatory authority can directly negotiate. However, as the telecommunications market becomes more diversified, involving both monopoly and competitive elements, regulatory issues, functions and procedures become more complex and decisions become more controversial. In such circumstances, a regulatory body with three or more members and a professional staff of economists, engineers and lawyers may ensure more balanced decision-making. The political structure of the subject country, including the number of political parties, as well as legal requirements (i.e., obligations to include a certain number of representatives of the labor unions on a decision-making board) may influence the number of members of the regulatory entity. Usually, however, a board of either three or five members is the most efficient. In the U.S., the FCC originally had seven members and now has five. Many experts believe that the larger structure was unwieldy and made decision-making difficult.

More crucial than size is the consideration of how the members of the regulatory entity will be appointed, approved and removed. Depending upon the legal form of the regulatory entity, members may be appointed by the president, the congress and/or the minister or secretary that heads the governmental department within which the agency is located. It is advisable to provide for selection process not only requirements for a mixture of political parties, but also to build into the selection process some checks and balances. For example, in the U.S., FCC commissioners are appointed by the President, but must be approved by the Senate. Additionally, the Chairman is selected by, and serves at the pleasure of, the President. If a new regulatory entity is part of a ministry, the members of the governing board may be appointed by the minister. This carries some risk that the commission or board may be too responsive to political shifts. However, this problem can be overcome by providing strict limitations on the circumstances under, and means by which, the members of the governing board can be removed.

The commissioners or board members should not be removable for any reasons other than adjudicated malfeasance, such as fraud or corruption. Any incentive and ability of the president, minister or the legislature to remove a commissioner or board member for political or policy reasons should be avoided. Instead, commissioners and board members should serve for prescribed terms. The terms may be staggered so as not to coincide with the presidential term or other political election cycle.

4.5 Legal Systems and Instruments

The nature of a legal system in a particular country will dictate the types of legal instruments that must be developed to establish the regulatory system. In a common law system, legal instruments at the highest level of authority are usually the most general, with increasing levels of detail provided by legal instruments in successively lower levels of the legal hierarchy. In civil law systems, greater specificity may be required at the higher levels of the legal hierarchy. In part this is due to relatively lesser reliance on judicial interpretation. Rather, unless the

highest level of legal mandate, e.g., a statute, provides an express grant of authority, the power to exercise such authority, e.g., through the issuance of an administrative regulation, or the negotiation of a concession agreement, may be deemed not to exist. Consequently, in civil law countries just now establishing telecommunications regulatory structures, it may be crucial to have regulatory goals and objectives, as well as the nature of particular regulatory tools that can be used, specified in some detail at the higher levels of the legal hierarchy. This may help to minimize disputes over regulatory powers. This may also reduce the flexibility that the regulatory entity has to address unforeseen circumstances, but it may be important, especially at the outset, to ensure the effectiveness of the regulatory process. In view of this, it may be useful to build into the process of the creation of a new regulatory system periodic review of the appropriateness of certain regulatory powers and tools.

In summary, the creation of a regulatory system requires a thorough understanding of the legal hierarchy in the subject country, and an appropriate matching of particular statements of regulatory goals, objectives, powers and tools with the appropriate legal instruments in that country. This can and should involve a detailed analysis of the objectives and policies, as well as procedures, that should be implemented from the outset for the reformed telecommunications sector. Ideally, such an analysis should be undertaken for each segment of the industry, (e.g., domestic basic voice services, international services, value added services, cellular and other mobile services, terminal equipment, etc.). The analysis would produce, not only an initial set of goals and policies, but also a strategic plan for the establishment of specific regulatory powers and authorities at each level of the legal hierarchy (including statutes, decrees, resolutions, regulations and concession agreements). In this way, the initial goals and objectives of sector reform in a partiular country, as well as the regulatory tools and powers necessary for such reform, can be comprehensively and appropriately identified.

4.6 Funding

The issue of funding is critical to the sustainability and effectiveness of a new regulatory system. Part or all of the funding for a new regulatory entity may come from congressional appropriations from the general treasury. Depending upon the structure of the regulatory entity, such appropriations may be allocated to the ministry within which the new regulatory entity is located, or to the commission, or agency itself if it is constituted independently from the ministry. Such general treasury allocations usually have to be justified annually, and may involve some substantive oversight by congressional committees of regulatory activities. Such general treasury allocations provide a good foundation for the regulatory budget. Other sources of funding may provide important supplements to the general treasury allocations.

An additional source of funds could be a percentage of the concession payment submitted by winning bidders in the privatization of the basic services telephone company or the grant of a valuable service franchise, such as a cellular telephone system. Such funds can provide a substantial resource in the early stages of regulatory reform. However, it is important to have some idea of the size of the regulatory budget early in the planning process, and it is difficult to plan a general budget based on uncertain receipts from a future auction. In any event, concession agreement payments, particularly from privatizations, may be very helpful for the initial establishment of a regulatory system, but a continuing source of annual income

should be separately identified.

A reliable and independent source of income that does not flow through the general treasury can enhance the independence of the regulatory process. Other sources of income for the regulatory system may be operator fees, taxes or surcharges and/or processing fees. Operator fees involve the assessment of particular amounts on different categories of service providers (e.g., the monopoly telephone company, cellular operators, satellite operators, private networks, etc.). Usually, the imposition of such fees would require legislative approval, and may require special authorization as a particular form of taxation. Additionally, arrangements must be made for the collection and accounting of such fees. Some countries may require that the fees be collected into the general treasury. If possible, if not collected directly by the regulatory entity, such fees should be "earmarked" for allocation to the regulatory entity budget.

Processing fees are not a tax, but rather are fees paid by applicants upon the submission of applications for facilities or system authorizations or for requests for regulatory approvals. A schedule of fees may be devised to cover a wide variety of regulatory activities. Again, arrangements have to be made to direct the receipts, or some substantial portion thereof, to the regulatory entity.

In structuring any schedule of fees, care must be taken to evaluate the tolerance in the market of such fees, and to avoid introducing any significant market distortions through the fees themselves. Fees should neither create nor alter market incentives. Additionally, fee structures and collection arrangements should be avoided that encourage the growth of the regulatory bureaucracy. Some control should always be maintained on the regulatory budget.

5. SPECIAL EXPERTS AND ADVISORY COMMITTEES

Any country establishing an entirely new regulatory system inevitably will experience a shortage of expertise in regulatory issues. Over time, this shortage can be ameliorated with special training programs. However, it is likely to take several years to assemble even a small staff with adequate training and background to address the myriad of complex legal, economic, technical and policy issues that will arise in the swiftly changing telecommunications industry. In addition to training programs for the long term development of expertise, several mechanisms may be considered for the short term to provide the new regulatory entity with expert advice.

First, every endeavor should be made to secure the highest possible pay scales for regulatory employees that are consistent with a particular country's civil service laws and requirements. This will help to attract to the new agency high level expertise already existing in industry, academia and private legal and economic consulting practices. Second, the regulatory entity may be empowered, perhaps under special legislation or residential decree, to hire outside experts on a contractual basis. Especially for the early years, access to the substantial expertise already developed in other countries would substantially facilitate in-house training. It also could be a critical element in the successful development of initial policies and procedures. Finally, a new regulatory entity may find substantial advantage in having access to either standing or ad hoc professional advisory committees.

Such committees may consist of representatives of the industry and/or other professional experts. Such an advisory committee would conduct factual analysis and made recommendations to the regulatory body, but would not have any

decision-making power. In the U.S., advisory committees are widely used by various government agencies, including the FCC, and are required to follow certain rules and procedures. Generally, ad hoc advisory committees, charged with developing a recommendation on a particular issue and constituted with the appropriate mix of accountants, engineers, lawyers and business representatives, may be most useful. A standing advisory committee may be able to provide only general advice on particular issues. Another potential disadvantage is that, depending upon the rights and powers granted to such a committee, a standing advisory committee may impose an additional level of bureaucracy on the regulatory process. This may impede efficient decision making.

6. PROCEDURAL ISSUES

6.1 The Need for Administrative Procedures

The establishment of sound and reliable administrative procedures is critical to the success of the regulatory effort. The purpose of such procedures should be to ensure the openness and fairness of the regulatory process. In some countries, administrative procedures are already established. However, even in cases where general principles of administrative procedure have already been developed, specific procedures for the operation of the regulatory entity must be identified. Such procedures will include, among other things, the manner of handling applications for services, negotiating concessions, adopting policies and issuing regulations, providing information to the public, responding to complaints and claims, handling challenges to regulatory decisions and providing members of the telecommunications industry with recourse against regulatory decisions with which they disagree.

6.2 Instruments of Regulatory Activity

New administrative procedures must be related to the specific tools that the regulatory agency will use in the conduct of its business. Normally, the regulatory authority will engage in some or all of the following activities: 1) adoption of general policies regarding classifications of services, technical requirements, allocations of frequencies to services and determinations of those portions of the market subject to competition, 2) assignment of licenses for radio facilities, negotiation of concession agreements, and review of tariffs and 3) resolution of disputes and investigations of complaints. Each set of regulatory activities will require specific procedures. Individual procedures for specific regulatory activities should be designed with reference to an overall framework. This overall framework should include a consistent approach to such issues as allowance for public participation in regulatory decision making and opportunities for challenge and/or judicial review of administrative decisions.

6.3 Public Access

One of the critical elements of an open and transparent decision making process is public access to information about the process. Public access takes many forms. First, the public should be apprised of the fact that certain applications have been filed with the regulatory entity. This permits members of the public as well as potential competitors an opportunity to evaluate or challenge proposals submitted to the regulatory entity for approval. The question of how much information about the proposal should be made public is a matter of protection of commercially proprietary information. Each country must find its own balance between satisfying the need for public access to information on th one hand, and protecting the interests of applicants

in secrecy and promoting efficiency, on the other. For example, in Australia under the proposed new rules for the new regulatory entity AUSTEL, formal procedures for public access have not been mandated, out of a concern for inefficiency, expense and delay. However, as a consequence, the openness of the regulatory process may be compromised.

The second form of important public access is notification of actions taken by the regulatory entity. Any decisions made by the regulator should be summarized, or published in full, in a volume which is easily accessible to the public. A requirement that agency decisions be committed to writing and published will enhance the credibility and consistency of the regulatory process.

An additional important feature of procedures for public access is control on lobbying activities. Specific procedures should restrict access by interested parties to decision making personnel on an "ex parte" basis. In other words, if other interested parties may be directly affected by the outcome of a particular decision, specific procedures should limit the ability of one interested party to gain access to decision making personnel without notifying or including the other interested parties. Certain other types of lobbying activities, including the giving of gifts of monetary or other substantial value, also me be restricted. Such restrictions would help to ensure the openness and fairness of the decision making process, as well as avoid incentives for corruption.

6.4 Enforcement Powers

In addition to decision making powers and procedures, the regulatory entity must have powers and procedures for the investigation of violations of regulatory requirements and the enforcement of such requirements through imposition of fines and other sanctions. Enforcement mechanisms may include, in addition to monetary fines, conditions placed upon a license or a consortium agreement, or ultimately the revocation of a concession or license. In addition to providing for the powers of the regulatory entity to enforce its decisions, enforcement procedures must also include avenues of recourse for regulated entities to permit orderly challenges to regulatory enforcement determinations.

7. CONCLUSION

The credibility and efficiency of the regulatory process will be one of the most crucial elements of any telecommunications reform. As described in this paper, the creation of a new regulatory structure is a complex and multifaceted undertaking. It also involves lengthy and complex efforts to identify the appropriate structures and procedures. Many times, there are severe time pressures under which telecommunications reforms may take place. Often, due to election timetables, there is a narrow "window of opportunity" for the enactment of telecommunications reform legislation. Sometimes such time pressures cannot be avoided, and statutes must be introduced, even if they are not optimum. In such circumstances, leaders of telecommunications reform must make their best efforts to come to reasonable compromises and put in place a functional regulatory mechanism. It may be just as well, then, to defer the passage of a new telecommunications law, if possible, and to implement a transitional approach by decree. In any case, it may be a good idea to provide for a review of the planned regulatory structure, after a certain time has passed and some experience with the market has been gained.

Mrs. Pisciotta has represented both governments and private companies in telecommunications and broadcasting matters, including privatization and regulatory reform projects in Japan, Australia, and New Zealand as well as in Latin America and Europe. Most recently, Mrs. Pisciotta advised the Venezuelan government on the creation of a new telecommunications regulatory system in connection with the privatization of that country's national telepone system, C.A.N.T.V.

DEVISING A WINNING STRATEGY FOR DEREGULATION

Paul Jansen
Principal

Michael Rennie
Senior Engagement Manager

McKinsey & Company, Inc.

The winds of deregulation are sweeping through the telecommunications services industry worldwide, to the benefit of most customers, but with significant, often negative, implications for the former monopolists. (Exhibit 1 lists the many countries that are planning to privatize telecom services.) McKinsey & Company's involvement in six of the most significant of these deregulation cases has allowed us to develop a deep understanding of the key challenges, strategy options, and shareholder value implications of major regulatory change. This paper takes the perspective of a dominant carrier's senior management and highlights the issues, sources of vulnerability, and strategic imperatives that must drive the response of a telecommunications company facing major deregulation.

NOBODY REALIZES JUST HOW MUCH IT WILL COST

Deregulation is often described as an event, but it is more appropriately viewed as a process that unfolds slowly, but with ever-increasing intensity. Consumer dissatisfaction with the price, quality, or availability of telecommunications services provided by the dominant carrier usually provides the initial impetus for change, although deregulation for purely political purposes or for the sake of following international trends is increasingly enough of a reason.

At the beginning of the process, government objectives are poorly understood, policy options only partially developed, and criteria for choosing among options ill-defined at best. Initial proposals are narrowly defined, focusing on privatization or the introduction of competition for a limited number of services. Dominant carriers often believe that such initiatives can be contained or that the value loss is not so great to justify a strong response. We would observe that, with the thin end of the wedge thus inserted, the opening of the door soon follows.

The cost of deregulation to the existing monopoly provider is usually grossly underestimated by the deregulating government and the provider itself. A telling measure of the shift in value is the cumulative return (stock appreciation plus dividends) to shareholders of the deregulated telecommunications company relative to other companies in the stock market. In the five years after deregulation in the United Kingdom, British Telecom's value compared to the market declined by 39%. This has been a relatively good result. In Japan, NTT's value has declined relative to the market by 70% since deregulation (Exhibit 2).

There are three major reasons for this decline in value:

- Competitors focus on the most attractive customers. This "cherry-picking" has a greater impact on the dominant provider's network economics than the expected share loss would suggest.
- Deregulation often tilts the playing field in favor of new competitors to give them a head start. Regulators rarely understand the extent of this tilt until it is too late and new entrants have made substantial, often unnecessary, investments.
- The monopoly provider often is ill-prepared for competition and loses significantly more share and profit than need be. Preparing for competition requires major cultural change as well as clear strategic positioning. Major cultural change takes years, leaving the company in a catch-up situation when it can least afford it.

WINNERS WILL DO FOUR THINGS WELL

We have suggested that deregulation is best viewed as a process with an increasing tempo. Importantly, it is also one with many stakeholders and therefore an array of often-conflicting objectives. The specifics of any deregulation situation will vary greatly, so no single recipe can cover

all situations. However, based on our work with dominant carriers, regulators, and potential entrants, we do see some common winning themes for organizations facing deregulation:

1. Manage deregulation proactively
2. Anticipate competitors' likely approach, and seek to gain a first-mover advantage
3. Shift as quickly as possible to a customer focus
4. Effect major cultural change in the organization.

Manage Deregulation Proactively

Our experience has shown that negotiating a well-structured regulatory framework is a more important driver of the dominant provider's financial performance in the five years after deregulation than achieving operating improvements or market growth. For instance, the difference in interconnect price arrangements alone can be worth approximately 30% of a major carrier's free cash flow.

As well as the obvious loss of value this causes, loss of free cash flow also limits capital competitiveness by reducing capital available for new network investment, new product investment, and capital-labor substitution at the same time the need for this is heightened.

The deregulation debate is particularly challenging to manage because the issues are extremely complex and in most cases interrelated (Exhibit 3). In our experience, this complexity often works against the telco. Lacking compelling proposals from the carrier, the regulator's solutions eventually are driven by political concerns and philosophical principals, and "the problem we are trying to fix" gets lost in the complexity of the issues.

Carriers facing deregulation must shape the debate on two levels. Discussions with the regulator must be detailed, purposeful, and pursued well before deregulation becomes a matter of public debate. Once public, the carrier's position must be positive and thematic. The most important issues that drive the shape of the competitive playing field, and therefore future financial performance, include the following:

- **Interconnect price arrangements.** Physical, commercial, and technical agreements with new competitors (e.g., equal access arrangements, network access charges, and equipment co-location requirements) will determine areas of competitive vulnerability.
- **Pricing flexibility.** Witness the enormous difference in outcomes between KDD and NTT because NTT is greatly constrained in its ability to compete on price (Exhibit 4).
- **Pricing mix.** Will access charges, which rarely cover costs and are subsidized by long distance and international, be restructured? The competitor will cherry-pick the latter and leave the dominant provider with the former.
- **Nature of the competition.** The key points here are the number of full network competitors and the arrangements for resellers.
- **Product market access.** Will the former monopoly be allowed to offer the full range of value-added or mobile services, or will it be precluded on the basis that competitors need an advantage to get started?
- **Profit regulation agreement.** Are returns capped or guaranteed? How will consumer prices be determined? Over what time frame is the agreement valid? Will the dominant provider have sufficient capital to compete in a tougher environment, especially when free cash flow is reduced by the impact of competition?

Successful deregulation management is not a zero-sum game. It is possible to "fix the problem" while wreaking minimum havoc on the dominant carrier's long-term competitiveness. To protect itself, the dominant carrier must stay one step ahead of the negotiations by rigorously assessing the economics and competitive implications of various options. Understanding what has happened in other international deregulation cases has proven extremely valuable in shaping an optimal outcome. These results of these inquiries must be coherently communicated to the government or regulator to help shape the deregulation debate, by introducing issues to be resolved and developing a common fact base for evaluating options.

Anticipate Competitor's Likely Approach

The dominant carrier must begin fighting in the new competitive arena even before its new competitor has been chosen. Analysis of a telco's business can pinpoint areas of weakness and predict a competitor's likely strategy. Very focused moves can then be made to minimize loss of share, customers, and

profit within the new regulatory framework.

For instance, the dominant carrier must understand:

- What routes and products are most susceptible
- What pricing flexibility is required to combat these threats
- What the impact of different interconnect terms will be on a competitor's ability to offer discounted services
- Which customers are most vulnerable and likely to switch to the competitor.

Internal "war games" - in which staff take on the roles of the former monopolist, competitors, regulators, and other interested parties - can significantly increase understanding of competitor strategies, the impact of different deregulation initiatives, and the viability of potential countermeasures. Fresh thinking on the strategies and economics of future entrants can also yield insight into ways to improve existing operations and deliver better value to customers who may be tempted to switch carriers.

Our experience suggests that a clear understanding of new entrants' likely programs and an effective first-mover response can reduce share loss by as much as 10-15%.

Develop a Customer Focus

The most critical shift the existing telco needs to make at the time of deregulation is to develop a clear customer focus. Without the pressure of competition, monopolies and regulators frequently adopt a "serve the average customer well" approach. This leaves some customers paying for service levels they do not value, while others feel underserved and frustrated at their inability to get better performance at any price.

It is customers who will decide whether to use the incumbent or the competitor. Much of the challenge in matching the competitor requires developing an understanding of customers to a degree never before necessary. Three major issues need analysis:

- What customer segments are there? What do customers in each segment really want, and what are they prepared to pay? Answering these questions is essential to develop the most effective product packages and pricing structures, and to create non-price sources of competitive advantage.
- Which customers are profitable and why? Which customers is the company prepared to lose, and how much will it cut price or increase service levels to retain profitable customers?
- How can the company increase switching costs so that existing profitable customers find it less attractive to shift to a competitor even on a trial basis?

Building the skills throughout the organization to carry out this level of analysis and the capability to deliver highly differentiated levels of customer support is critical to success. Programs must be developed before the competition arrives to attenuate customer complaints and allow time for experimentation and refinement.

Move the Internal Army

Jan Carlzon's comment on the importance of customer interactions in the airlines industry, "40,000 moments of truth," is equally applicable to today's competitive telecommunications environment. Every front-line customer interaction must be better than those of the competitors. For most customers, switching costs are low, and any interaction may prompt switching or retention. The internal army must be moved along a number of dimensions to achieve a new external, customer-focused, results-oriented perspective (Exhibit 5).

This type of deep-reaching organizational change is the hardest task of all for telco managers facing deregulation. Significant structural change is also involved, such as replacing functional departments with customer-specific business units. Cultural change on this scale can take six to eight years with a very committed and focused team. Most companies facing substantial deregulation, however, typically only have two to four years.

Our recent experience working with telcos over the past five years has led us to believe that major change can be achieved in this timeframe, and typically requires three distinct phases of activity:

- **Preparing for change:** This stage involves developing the commitment and a commonly shared vision in the top management team and tailoring a program to ensure change reaches pivotal front-line and middle-management positions.

- **Making change happen:** For customers to see real results, change must happen at all levels of the organization. Competitive pressures often necessitate that it happen everywhere, at once. This involves virtually everyone in the company and thousands of man-years of focused effort aimed at bridging the gap between current and future required levels of performance.

- **Ensuring the change becomes self-sustaining:** Systems, processes, and the internal mindset of all staff must be changed to encourage continuous improvement. Employees at all levels must learn to benchmark performance, diagnose the causes of performance gaps, and roll out new approaches to achieve continued improvement.

At one telco, a two-year program of this nature has led to significant results: customer dissatisfaction fell 85%, productivity improvements averaged 9% per annum, and profitability increased over 400%.

CONCLUSION

How an incumbent telco faces deregulation will determine its performance over the next 20 years. Virtually everything is at stake, and the challenges are enormous.

The telecommunications industry may well follow a path similar to that of the airline industry. Changes in the technology and resulting economics of international services will lead to bypass of domestic providers within the next 20 years, with only 10-12 major players dominating the global scene. Enormous international service opportunities may exist and can be very profitable if well managed, as illustrated by Cable and Wireless' performance. In the rush to provide domestic competition, governments can unwittingly give away a local telco's chance of long-term growth and even survival.

Telcos facing deregulation can benefit substantially from those who have gone before. These experiences suggest that winners will take aggressive steps to prepare for competition. They will:

- Proactively manage the deregulation process to achieve important objectives while compromising in areas of lower competitive impact

- Identify competitors' likely line of attack and remove potential weaknesses before they can invest

- Develop a deep understanding of customer needs

- Embark on major internal cultural change well in advance of competitive pressures.

TELEWORK TROUBLES, TRAUMAS, AND TRIUMPHS: CONFESSIONS FROM TELEWORK PLANNERS AROUND THE PACIFIC RIM

by

Gil Gordon
Gil Gordon Associates - Monmouth Junction, NJ USA
Wendy Spinks and Norihiro Katada
Institute for Economic and Financial Research - Tokyo, Japan

1. ABSTRACT

Telework has become increasingly popular in many countries around the Pacific Rim. While there has been much success, there has also been skepticism about how little has been reported about the problems and obstacles. This paper will cite examples of these problems in areas such as employer willingness, union reactions, technology issues, and social, cultural, and public policy areas. A full understanding of these problems is important for telework planners and implementers.

2. INTRODUCTION

Telework has progressed from being an unusual idea to a successful, accepted practice in many countries around the Pacific Rim. While it is by no means common, and its introduction is proceeding slowly, this innovation is no longer just an interesting novelty.

Published reports about telework have been criticized by observers who claim that telework proponents have reported much more about the successes than the failures, and much more about the outcomes than about the difficulties encountered while progressing toward those outcomes. This paper will address these concerns by drawing on the experiences of telework planners and implementers in the US, Japan, Australia and New Zealand.

"Telework" as used in this paper refers to the decentralization of the traditional office, by allowing certain workers to spend part or most of the work week working elsewhere. Other work locations typically include a work area in the home or a "satellite office" at which approximately ten or more workers are located. The satellite office is generally located in or near the residential areas where the workers live, or part way between those areas and the traditional center-city office area.

Most important, we are discussing the regular, routine substitution of these work locations for the traditional office, and we are not discussing so-called "mobile workers" (such as sales representatives or others whose jobs are normally done away from the office) or work done at home during the evening or on an occasional day spent away from the office.

Our goal is to further the understanding of telework by offering a candid discussion about the less-than-successful aspects of the field. The purpose is not to place or take blame, but to balance out some of the existing literature with an assessment of telework problems and challenges. The authors believe that telework is a feasible and practical work method, with potential for much more success than problems as long as it is implemented correctly.

In addition to our own experiences in our respective countries and elsewhere, we gratefully acknowledge the contributions of David Fleming (State of California - US); Paul Chung (Telecom Australia), and Laurence Zwimpfer (Telecom of New Zealand). The comments of these three do not necessarily reflect the official positions of their employers.

3. CURRENT ASSESSMENT OF TELEWORK IMPLEMENTATION

Despite the significant growth in telework, the traditional center-city office is in no danger of becoming empty. The majority of office workers do - and will - work in their offices. While up to 60-65% of the workforce in most developed countries could be classified as information workers (and therefore at least somewhat suited to telework), it is likely that most employers will not exceed a level of 5-10% of their workers as teleworkers.

The interesting and encouraging aspect of telework growth, especially in the US and Japan, is that the rate of growth is increasing. This is typical of many innovations where there is a long, slow introduction period followed

by more rapid acceptance by a wider audience. Within the US, for example, our estimate is that the number of employers who have started new telework programs (whether formal or informal) in the last 18 months is more than the number who began in the previous 3-4 years.

Despite these positive results, telework is far from a widely accepted, widely used practice. In some ways there has been very little cumulative learning, i.e., the same questions or points of resistance that are raised in 1992 were raised in 1982 - even though there are good answers available for these questions. This is frustrating because it suggests that some larger, underlying problems exist that explain the resistance. We hope this paper sheds some light on these problems.

4. SPECIFIC PROBLEM AREAS

We have identified six areas that are part of the telework picture, both when it is successful and unsuccessful. These are listed below as separate problems, but in reality many or most are closely related.

We would like to restate our belief that telework is fundamentally a useful and valuable method for solving some of the problems facing employers, workers, and society. It is impossible to rely only on traditicnal solutions to some of these problems. For example, we cannot solve the traffic and mass transit "gridlock" problems in Tokyo, New York, Los Angeles, Sydney, or other major cities around the world simply by building more roads or adding new train lines. Government funds for these projects are more limited than ever; even if money were not a factor, these new routes would quickly become just as congested as the old ones.

Telework is increasingly making its way into the public policy agendas in the countries cited in this paper and others, as well as being adopted by private employers who are seeking to reduce operating expenses, attract and retain qualified workers, and increase productivity by allowing workers to work in more relaxed settings without having to endure the stress of commuting.

4.1 EMPLOYER WILLINGNESS

The consensus is that employers do not easily embrace telework unless they have a specific reason to do so for which there is no other solution. This is, oddly, both an advantage and a problem. It is an advantage because it reinforces the view that telework should be a business solution to business problems, and should not be used just because of its popularity. It is a problem because it suggests that the more innovative uses of telework are limited if they are not obvious solutions to today's problems.

There were several obstacles noted in our analysis of employer resistance:

A. SHORT-TERM THINKING: Cost-conscious managers required to meet short-term profit (or other) goals are unsure about the cost-benefit ratio for telework. This problem is made worse because the up-front costs are more obvious than the benefits; telework planners have not done a good job in quantifying those benefits.

B. RISK-AVERSE THINKING: Despite all the talk about the need for risk-taking and innovation, we observe that most managers resist change and resist innovation. The relatively rare cases where a high-level manager is a telework "champion" are exceptions; in other cases, it seems that most managers support the idea with words but rarely with their actions.

This problem is most notable in economies like New Zealand, where the last five years of economic decline have forced employers to cut costs – and, unfortunately, innovation – in order to survive.

C. SATISFACTION WITH STATUS QUO: Even though the daily commute and the noise and distractions of today's offices are seen as problems, most managers have become accustomed to them. In Japan, for example, head-office staff is mostly male, with a built-in support system at home (known as the wife) to take care of child care and elder care. Therefore, the consequences of the long commute on the family are not acknowledged as a problem for the manager - so he is unlikely to be motivated to find an alternative. We observe that many Japanese companies aren't resisting telework as much as they are ignoring it, because there is little bottom-up pressure for an alternative.

D. THE "FEAR" PROBLEM: We are grateful to David Fleming for defining the FEAR problem as "False Evidence Appearing Real." In other words, managers are insecure about what they <u>think</u> will happen if they allow or encourage telework, e.g., they will lose control of their workers, be unable to supervise effectively, and lose status themselves.

These entrenched management attitudes are related to Industrial- Age thinking in which managers had to produce a physical product in a factory; they do not fit with Information-Age reality,

and are not supported by evidence from successful telework programs.

E. ISOLATED PROBLEMS, NOT WIDE TRENDS: We see more use of telework in companies facing strong competition in the labor market for skilled workers, because these firms know it helps attract and retain qualified workers. However, these labor shortages are isolated and sporadic - or at least that is the perception. In reality, virtually all Pacific Rim countries now (or soon will) face growing shortages for professional and technical workers.

One reason for these shortages is that employers continue to recruit only from among those people who can and will come to the office five days a week. This eliminates other good workers who could be teleworkers.

F. LACK OF INCENTIVES OR PUNISHMENTS: With the exception of local trip-reduction regulations in several sections of California and other U.S. states, there is no regulatory or financial incentive for employers to adopt telework. Similarly, there is no public recognition or incentive for the employers who use telework - even though it is believed that telework provides public benefits. With neither a "carrot" nor a "stick" available, companies will tend to remain with the status quo.

In summary, we believe that the lack of widespread willingness to use telework reflects complacency and lack of understanding of all aspects of telework and its benefits. To a degree, it also reflects conscious rejection of the telework concept, but we do not believe this is the main reason for low levels of use.

4.2 EMPLOYEE ADAPTATION

Here, we are concerned with the effects of telework on the teleworkers themselves - have these been generally positive, or are there problems that outweigh the benefits?

We believe that problems for teleworkers fall into two categories. First, there are administrative problems - these are generally avoidable but unfortunately they have not been avoided in all cases. Second, there are conceptual problems - these are more serious problems that arise even if telework has been implemented in the manner that reflects the best practice known.

A. ADMINISTRATIVE PROBLEMS include items such as poor selection of teleworkers, poor or non-existent training for them and their managers, inadequate technical support, inadequate guidance about how to prepare the family members for this change, and lack of ongoing support and "fine-tuning" once the program has begun.

These are particularly frustrating problems to telework planners because there are proven and simple solutions. These problems continue because some managers who choose to implement telework do so with very little, if any, planning. This is a prescription for failure, and very often it is the teleworker who fails.

Some of this relates to the personality of the manager, but it also relates to the age gap between managers and their teleworkers. For example, many Japanese men in their forties have difficulty using a photocopier, let alone a PC. Thus, when it comes to helping teleworkers equip themselves, or communicating them over a distance via electronic mail, the managers cannot perform. The result is poor performance and frustration for the teleworkers.

B. CONCEPTUAL PROBLEMS are more complex. For example, these include the question of how and whether telework will affect the career progress of teleworkers. Informal evidence in the U.S. suggests that teleworkers are at least as promotable as before, mostly because they learn and use new skills that qualify them for promotion, and because their work is now more visible than before. But the perception lingers that being "out of sight" is "out of mind" for the next promotion.

In Japan, it is impossible to draw any conclusions yet because of the early stages of experimentation. We expect, however, that the career progress issue will be a problem because of the difficulty in doing performance evaluations even in the head office. This will become even more strained if teleworkers are separated from their managers.

We would like to note that the broader question of career progress in today's flattened, "downsized" organizations means that our old assumptions about upward mobility must be changed. We have heard from teleworkers who say that they welcome the privilege of being allowed to telework because it is a more certain form of "reward" than the uncertainty of upward mobility. For them, telework is a type of career progress and development; this is in addition to the personal and family benefits it offers.

In some of the countries studied, much of the interest in telework comes from the self-employed (for whom home-working is the most sensible economic choice), and from salaried teleworkers doing so

informally because of lifestyle benefits. We believe this kind of grass-roots interest in telework is strong support for the view that it is a preferred style of work for some.

4.3 UNION REACTIONS

At best, unions have been skeptical about telework; at worst, they have been openly resistant. Much of their reaction is based on the history of abusive industrial home work around the world. To their credit, the unions have fought hard to restrict or eliminate this. But we believe that Information-Age telework is quite different from the old-style home work.

It appears that union reactions are sometimes based on lack of knowledge about telework. In some cases in the U.S., for example, union leaders have not accepted invitations to be involved in early briefings or planning sessions for telework pilots. In other cases, they have made initial demands that reflect their lack of understanding about telework. For example, one California union wanted teleworkers to be selected based on seniority - with no regard for job performance, type of work, or other factors.

In Japan, it should be noted that unions are company unions and not trade unions, and there is not the kind of adversarial relations as sometimes exist in trade union settings. Japanese unions appear to have taken the position that as long as there is equality in allowances (e.g., for housing or urban living costs), there is no great problem. In the NTT telework pilot, for example, teleworkers have been placed on long-term business trip status for administrative purposes, so they can continue to receive their urban living allowance even though they would no longer qualify for this allowance based on the suburban location of their satellite office.

Perhaps the biggest concern of unions is that telework will lead to (or is part of) a plan to convert regular full-time workers with full benefits into part-time or contract workers with lower wages and reduced or no benefits. It is this fear about the loss of hard-won wages and entitlements that motivates resistance, as well as the related fear that it would be harder to organize and represent a dispersed, decentralized workforce. Unions derive much of their power because of their collective strength; to a degree, this depends on workers being together in groups.

Further, some unions have expressed the concern that the selective nature of telework (i.e., it is a specific kind of job assignment open only to some workers) contradicts the basic union principle of equity and equal treatment. In Japan we have seen companies spend a lot of money to set up and furnish satellite offices; the money saved on lower-cost satellite office floor space more than justifies this expense. Thus, the work environment there is often better than in the head office. While this is clearly a benefit for the satellite office workers, it does put them in a position with slightly higher status. It will be interesting to see the union reaction if and when telework spreads in Japan and we see less elaborate satellite offices.

Another factor is the timing and degree of union involvement in telework planning. We believe that this is one of the best predictors of acceptance by union leaders. In cases where the employer planned telework with the union - and listened to its concerns and suggestions - the project went more smoothly. In cases where it was done with only minimal union involvement, there were, understandably, more problems and more resentment.

4.4 TECHNOLOGY ISSUES

We believe that there is a gap between what has been promised or advertised about technology and what actually is available at reasonable cost. There is no doubt that there is adequate technology to handle many telework applications today, but there are some technology "thresholds" that have not yet been crossed.

One particular concern in Japan is the diversity of computers and word processors available. In the U.S., Australia, and New Zealand, the IBM and Macintosh standards are quite common; in Japan, PCs from IBM, Fujitsu, Oasis, and NEC are widely used and don't communicate with each other - not to mention an even wider range of word processing equipment. This makes it hard to set up telework unless the equipment is all from the same vendor.

Apart from the equipment concerns are the bigger problems of telecommunications connections. Dial-up charges in the U.S. can be very costly for teleworkers who spend much of the day connected to mainframes or LANs at the office; this is complicated by having to use transmission speeds of 2400 bps or less. The much-heralded ISDN should make these and related problems shrink if not disappear, but ISDN is not yet widely available in most Pacific Rim countries - with Australia being a notable exception.

There is also a problem with determining fair and appropriate line charges for teleworkers. Neither one of the traditional classes of service (residential or business) fits the teleworker; innovative phone companies are starting to offer a new class of service for certain telework applications; this should be an attractive (and cost-effective) strategy.

A related problem is the spread of technology vs. the spread of teleworkers. Whether they are working at home or in satellite offices, teleworkers who work in suburban or rural areas often don't have access to the same telecommunications services as in metropolitan areas. This is, obviously, because the telephone companies make their first investments in new technologies where the population density is highest. This sets an effective limit on the amount of dispersion via telework.

There are other technology problems for which solutions are available but either costly or underutilized:

A. DATA SECURITY: The objection is often raised that some jobs are too confidential to be done away from the head office - yet in these same companies, an office worker can carry out computer printouts or diskettes with the same "secure" data in his or her briefcase without being challenged. Also, there are elaborate monitoring systems in place to detect and record unauthorized attempts to dial into company computers from a remote site - yet the reports generated by these systems are sometimes not reviewed to determine if these unauthorized attempts were made.

The irony is that the same company that has these kinds of security failings will be critical of telework because it supposedly presents a major security risk. This is not necessarily the case, but the belief prevails and is one more reason why telework is not permitted.

B. UNPREDICTABLE LINE QUALITY: For certain telework applications where reliable, high-speed data transmission is a requirement, the use of existing local-loop, voice-grade phone lines is a risk. These include applications with frequent transfers of large files to and from the mainframe, or teleworkers who handle incoming toll-free calls (for travel reservations or catalog ordering). If the employer must pay for a separate leased line to be sure that the teleworkers can work without inconvenience, the cost of telework goes up substantially.

C. USER-UNFRIENDLY COMPUTERS: Despite all the advertising about "user-friendly" computers, the fact is that many PC applications are not quite as simple as we would like. With the exception of the small number of true PC technical geniuses, most of the rest of us run into problems quite regularly. If we are in the office where we can turn to a colleague - or a nearby genius - we can solve these problems.

If we are teleworking, we can still "turn" to the expert by making contact via telephone, voice mail, or electronic mail. Also, a few telephone companies are starting to provide online and/or call-in support support services for teleworkers. These solutions aren't quite as easy but they do work.

The problem is not with telework itself but with trying to use hardware and software that is still considerably more difficult than using a VCR or microwave. The growth of Macintosh sales and in Windows-based applications for the IBM world should help this problem, but it won't go away overnight.

D. VIDEOCONFERENCING: Last, we must make mention of this tool and its role in telework. It is often cited as the most important innovation because it will allow the kind of face-to-face contact that we are accustomed to when everyone works in the office. The last 2-3 years have seen a dramatic increase in videoconference capabilities with a decrease in costs - these are two favorable trends. However, it still is not as simple as turning on our TV set at home to watch our favorite show.

We believe that videoconferencing does have a role in the growth of telework, but that for the immediate future it will be used on an exception basis and not very routinely. We do not believe that this is an obstacle - in fact, there are many cases today where simple audio conferencing is being used very successfully to bridge the distance between the telework location and the head office. But the obstacle is the perception of managers that the video portion is needed. This reflects the Industrial-Age thinking that says, "If I can't see them, how will I be able to communicate with them or know that they are working?"

4.5 EFFECTS ON HOME AND FAMILY LIFE

Even though many employers claim that they are not interested in their employees' home and family lives, the reality is that they cannot ignore this completely. Telework can have a major effect on home and family life, though this is more common in the work-at-home form of telework. Since very little of this form occurs in Japan (due primarily

to smaller home sizes), and because small home sizes in other Pacific Rim countries will pose similar problems, we will comment mostly about the American experiences first.

One advantage of commuting to the traditional office is that the boundary between home life and work life remains clear. However, when the teleworker lives and works under the same roof - even if only for 2-3 days each week - this boundary becomes unclear. In some cases this creates unexpected benefits - and in others it creates unexpected problems. The benefits (such as more time available with other family members) have been widely reported elsewhere and will not be covered here.

Two of the potential problems are as follows:

A. RISK OF OVERWORKING: It has been said that home-based telework can be the "workaholic's dream." When we eliminate the commute, the workaholic can work almost unlimited hours. This may seem like a benefit to the employer, but we must remember that these hard workers sometimes burn themselves out - and create serious strains within the family as well.

B. CREATION OF NEW HOUSEHOLD TENSIONS: In every household there is a division of labor. We would observe that this division is rarely completely satisfying to all household members. Telework allows a reassessment of this division, but this sometimes creates more problems than it solves if the teleworker is expected to take on more household duties. For example, consider the teleworker's spouse who comes home from the head office and says to the teleworker, "Why haven't you prepared dinner - you were home all day!"

When looking beyond the U.S., we note that the phrase "home and family life" has a very different meaning in Japan and in other Pacific Rim countries. In Japan, for example, long absences by and little contact with the father are the norm. Some people we consulted in Japan went so far as to say that family life doesn't exist in the modern corporate worker's home!

The satellite office worker in Japan may be able to spend more time at home in the early morning and early evening because of reduced commuting time, even though he does not work at home during the day. This can open up new possibilities in family relationships - but these relationships can have their own problems as the family tries to adjust to this new pattern.

One teleworker in Japan told us that he had more time with his family when he was assigned to a nearby satellite office - but when he was sent back to the head office it was very hard on his children. They could not understand why their daddy wasn't taking them to the bus stop in the morning any more. Telework planners caution teleworkers that they should not make any permanent changes in habits or lifestyles at home if their telework assignment is likely to be temporary, as it often is. However, problems like this "bus stop" adjustment are not uncommon.

In summary, we have seen many cases where home and family life have improved greatly because of telework - in fact, this appears to be the norm. But there are cases where there are as many problems as improvements. Whether it is home-based or satellite office telework, employers must help their teleworkers understand what kinds of changes might occur and how to cope with them. This type of training and support has not been provided as often or as widely as needed.

4.6 SOCIAL, CULTURAL, AND PUBLIC POLICY ISSUES

This is a broad category of concerns dealing with population dispersion, the relative merits of urban vs. rural life, the effects of telework on the communities, the role of the auto as the main commuting method, and the desirability of adopting new models of regional planning.

One factor that affects telework growth is the presence or absence of government policy to encourage or restrict that growth. In the Pacific Rim countries there is a wide variation in the level of interest and involvement by various government agencies. As we reported in our 1991 PTC paper ("Contrasting Roles of Public Policy in Telework Development in the United States and Japan"), the telework concept is just beginning to make its way into the vocabulary of government planners. This is a slow process but we have seen dramatic improvements during 1991 and expect this to continue.

We note the following issues as impediments to telework growth:

1. DOMINANCE OF THE CENTRAL CITY AREA: Despite years of growth in suburban areas, the traditional "downtown" areas are still seen as the focal point of business and government activity. There is a large infrastructure in place that reinforces this idea; mass transit, for example, has been designed to move people from suburbs to downtown, not from suburbs to suburbs.

There is also the perceived status of being located in the prime commercial district. Companies that are interested in satellite offices sometimes find that their workers do not want to work at those "remote" locations because they fear that their status (in the eyes of colleagues or competitors in other companies) will be decreased.

2. URBAN SPRAWL VS. RURAL DEVELOPMENT: In the U.S., the concern has been raised that telework will encourage more people to move even further away from the cities to areas too distant for easy commuting but very suitable for teleworking. Critics claim that this will spread the ills of urbanization even further out into the unspoiled countryside. By contrast, in Japan we find that this kind of spread is exactly is what is needed to deal with the over-concentration of people and jobs in metropolitan Tokyo. The rural areas could benefit greatly from this kind of dispersion of work as a means of rural economic development.

With the exception of some preliminary work being done by the National Land Agency in Japan, we do not see any signs that land use planners in Pacific Rim countries are making efforts to include telework in their planning. One possible exception is a recent comment by Gordon Campbell, Mayor of Vancouver, British Columbia. He said that "the day of the traditional bedroom community is gone ... we can no longer afford that kind of separation between living and working areas. It's just not realistic or desirable to expect downtown Vancouver to be the single job center for seventeen municipalities in this region."

3. THE DOMINANCE OF THE AUTO: It is often noted that Americans (and Californians in particular) are married to their cars; the single-occupancy vehicle is still the main commuting method in many areas, despite extensive traffic problems. Even after year after year of increasing traffic congestion, we still hear that governments are ready to spend more money to build new roads or widen existing ones. So-called "smart highway systems" are now suggested as high-tech gridlock solutions, yet these multi-million dollar experiments are unproven and do nothing to deal with the underlying problem of too many cars on the road.

Similarly, mass transit programs are not the complete answer. These presume the kind of suburb vs. center-city separation that may no longer be desirable. Also, cities like Tokyo or New York already have extensive mass transit systems in place; they are highly utilized during peak commuting hours and cannot be expanded without incurring huge costs.

We are troubled by the fact that transportation planners have not gotten the message that spending only a portion of the cost of a new subway line or expressway could pay for the start-up costs for thousands of teleworkers. The net cost to society of continuing to transport millions of workers is overwhelming, yet we continue to look for new ways to move the workers instead of moving the work itself electronically.

Government policy in many countries seems to evolve from reaction to crises, not from careful planning. In the U.S., for example, the Interstate Highway System was "sold" based on our presumed vulnerability during and after World War II, not because of a forward-thinking national transportation policy. Similarly, we saw a great deal of ad hoc telework develop in San Francisco after the 1989 earthquake, and some observers note that an even higher level of telework would be evident if there was another Arab oil embargo.

We do not want to imply that we welcome these disasters or disruptions. The problem is that the "crisis" created by today's tradition of commuting is much less visible and much less immediately painful than an earthquake or oil embargo. The cumulative effects of gridlock, air pollution, disrupted family lives, and reduced productivity simply aren't the kind of issues that politicians can rally around.

What is worse is that powerful economic and political forces exist to maintain the status quo. The auto, oil company, office and highway construction, and mass transit construction industries all exert significant pressure on governments; any serious attempts to promote telework would likely be met with strong resistance from these industries. By contrast, the telecommunications and computer industries have not been able to get as much attention from politicians, though this is starting to change.

We believe, therefore, that telework growth will be largely a private-sector activity. (The popularity of market-based economies - with minimal government intervention - is one reason for this belief.) Public policy can be used selectively to encourage this growth - and perhaps to stimulate it with low-cost tax incentives. It is more likely that satellite office telework will attract the attention of government planners because these facilities are more tangible and visible than at-home telework. Also, networks of satellite offices for up to several hundred teleworkers each will have a much greater effect on traffic congestion and air pollution - and satellite offices

are likely to be the predominant form of telework growth in many Pacific Rim countries where residences are too small to accommodate a dedicated work area.

5. CONCLUSIONS

The dilemma of telework is that we know it works - and works well - where it has been implemented correctly, yet it has not been as widely accepted and utilized as expected. If it were not for the fact of the very positive evaluations from teleworkers and (more importantly) their managers, we would be less optimistic about telework's future.

The problems described in this paper are typical of problems that arise when an innovation is thrust in the middle of tradition. We must remember that "going to the office" is a part of the language all around the world. When the office becomes a spare room down the hallway at home, or a comfortable workstation in a nearby satellite office, we have done more than change the language. We have begun to tamper with long-established norms and policies, and whenever that happens we can expect resistance.

We continue to believe that telework will become accepted as a legitimate and beneficial work method. It will not replace the traditional office, and we all will not be working at home in our blue jeans.

The growth and economic vitality of the Pacific Rim countries depends on having a steady supply of qualified, productive workers, and on a quality of life that is not threatened by gridlock, pollution, and vast differences in urban vs. rural economies. Telework is one method to help insure this vitality, and we look forward to continued progress in overcoming the kinds of problems noted in this paper.

A TRIAL OF TELEWORKING AND TELELEARNING
— Practical approach in the communication software field

Kiyoh Nakamura, Jiro Tsuboi, Hitoshi Ito and Yukio Kiyokane

KAWASAKI 211, JAPAN

1. ABSTRACT

Out of our commitment to telecommunications software development as a teleworking model over the last few years, we have set up teleworking offices in eight cities throughout Japan. This paper focuses on two issues, teleworking, of the transmission of informal or contextual information among distributed offices and the improvement of teleworking. It proposes a communication system for teleworking and a telelearning system for improving the capability of teleworkers. The key for this purpose is to transmit business-oriented information, as well as informal or contextual information for the good relationship among teleworkers at distributed office.

2. STATUS OF JAPANESE TELEWORKING

2.1 WHY IS TELEWORKING NEEDED?

The continuing convergence of population in the metropolitan city of Tokyo has led to a host of annoying problems, such as rising land prices, high rents for office space, long commutes, a housing shortage and air pollution. Organizations such as the Ministry of Posts and Telecommunicatuins, the Ministry of International Trade and Industry (MITI) have been working on experimental projects for better office distribution. On January 30, 1991, the "Japan Satellite Office Association" was founded by 21 business entities. This foundation is aimed at promoting the development of offices outside the Tokyo metropolitan area. These has been serious discussion in Japan, on the need to distribute offices and encourage teleworking. This argument is supported by the following observations:

(a) Problems caused by the concentration in Tokyo
- Increase of land prices
- Housing shortage and long commutes
- Traffic jams and air pollution
- Shortage of public facilities for residents

(b) Changes in employment structure
- Shortage of young workers
- Improvement of social status of women
- Reduction in working hours
- Return to hometowns

(c) Social problems
- Insufficient space and office buildings
- Aquistion of excellent human resources
- Housing shortage and long commutes

(d) Individual requirements
- Comfortable office environment
- High-quality work at own pace
- Changes in sense of value (More emphasis is put on individual life style than on the company)

2.2 CLASSIFICATION OF TELEWORKING

In Japan, teleworking has been experimented with on a trial basis. The following teleworking styles are proposed.

(1) Home offices linked via telecommunication
(2) Suburban satellite offices (Offices and housing are close to each other)
(3) Satellite offices in regional cities
(4) Resort area offices (Offices and resort area are close to each other)

Up to now, writing, translation, building design and a few other types of work have been carried out in offices at private homes. The telecommunication technology has promoted working at home.

Some people work in satellite offices in the suburbs near their homes. This work is aimed at solving the problems of insufficient office space in downtown Tokyo, and freeing people of long commutes.

The third concept is to set up satellite offices in to major regional cities connected by a high-speed digital network to allow the same activities to be deployed at each of them. Setting up offices outside Tokyo not only contributes to the development regional areas, but also enables more engineers to be employed. This idea is expected to work well in Japan.

Resort area offices is another idea which should work well in Japan. People work at offices located in resort areas for a certain period depending on the purpose, usually three days to one week, or at most one month. These offices will complement other distributed ones.

2.3 OUR APPROACH

Fujitsu's communication software division has implemented teleworking in offices at major regional cities. Eight local offices have been set up to practice various approaches aimed at improving the worker environment, improving software productivity, and implementing of properly distributed programming environment. Given below is a description of our concepts and requirements for a teleworking environment.

Concepts
- Comfortable working environment
- Smooth communication among distributed offices
- Performance of the same business activities as at the centre office
- Achievement of higher productivity than at the centre office

Requirements of teleworking offices
- Location in the downtown areas of regional cities
- Extension and implementation of integrated telecommunication network
- Easy accessibility
- Implementation of functions for improving the quality of life

Teleworking environment
- Assignment of one workstation and telephone per teleworker
- Installation of LAN plus server facilities
- Sufficient office space
- Enough review rooms, large enough break area

We have also been promoting an "Excellent-Work-Way" (E-W-W) that targets the work style allowing individual creative capability to be drawn out fully. "E-W-W" is expected to spur teleworking. The concept of "E-W-W" involves flexible working at an individual's own pace. It is aimed at implementing rapid flat communication via electronic documents rather than face-to-face communication. It is also intended to build a data base containing design know-how so that everyone may share design data and information in any office. The following goals must be met:

Implementation of comfortable office environment
- Extend and improve office space containing physical facilities such as data telecommunication equipment, as well as to carry out concentrated working and construct a relaxing environment. Interruptions such as the ringing of telephones will be reduced and jobs will be embarked in at an individual's own pace.

Effective use of non-realtime communicaton
- Apply non-realtime communication means allowing each person to work at their own pace as well as realtime communication like telephone, and to set up the corresponding work style.

Location independence access to data and information
- Allow each workstation on engineer's desk at any distributed office to access needed data and information as well as the centre office.

3. COMMUNICATION AMONG DISTRIBUTED OFFICES

Discussed first in this Section is "communication among distributed offices" as a major issue of teleworking. Such communication depends on the information to be transmitted in the process of software development, on the strategy of transmitting the information, and on the communication system to be used. Further, we must take into account what is insufficient information and what system supports it.

3.1 COMMUNICATION ANALYSIS

One of the requirements for encouraging teleworking is that we understand the contents and characteristics of communication among offices engaged in developing distributed software. Communication can be investigated by the following methods:

(1) Analysing processes of software development to survey communication derived in each process
(2) Surveying dynamic information flow among offices

(3) Sampling contents of work by engineers
(4) Conducting a survey by passing out questionnaires to engineers

The clear definition of the development process is important for improving the productivity and quality of software development. It is thus necessary to clearly understand communication in the development process. A survey of dynamic information flow will help to identify unexpected communication not covered in the development process. Modeling communication on the basis of the results for the above investigation will contribute to determining what communication means are needed and what working style is appropriate.

Using above method (2), we have investigated into what communication is carried out in the distributed office. Here are the results of this investigation. We focused on engineers engaged in developing software at the distributed office. Data on the contents of communication over telephone and facsimile. Figure 1 shows some results, which tell the following:

(a) Communication is carried out more frequently in certain places, especially the centre office. More than 90 percent of the communicators are personally acquainted with each other. This communication is thus supported by friendship.

(b) Overseas communication is carried out more frequently by facsimile than by telephone due to time differences.

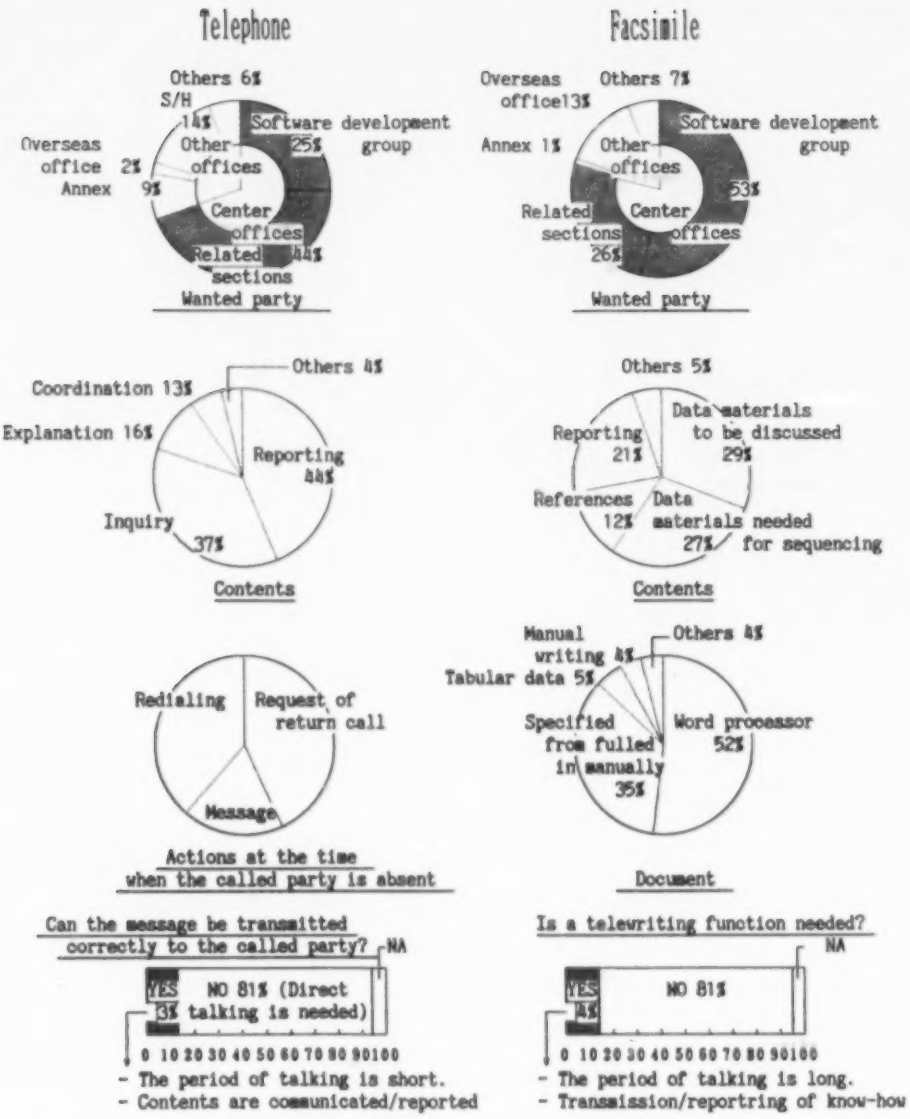

Figure 1 COMMUNICATION AMONG DISTRIBUTED OFFICES

(c) In most cases, communication by telephone requires direct talking; If the called party is absent, 80 persent of the callers will redial later or request to be called back. This means that, in many cases, a function for recording a message is less important than an indication that the called party should dial the caller.

(d) The type of information sent by facsimile includes design documents and progress report data. These documents and data can also be transmitted by electronic mail system (E-mail).

3.2 INVESTIGATION INTO TELEWORKER'S CONSCIOUSNESS

The questionnaire (Figure 2) targeting teleworkers tells that their anxiety and dissatisfaction is related to the items below.

[Young teleworker]
- Difficult to acquaint with staff members in the centre office and feels constraint in asking questions.
- Does not know who to ask a question to.
- Wants to visit centre office.

1. Problems of distribution

(1) Time lag of information transmission, loss of chance, and time loss
- No information can be accessed timely.
- It takes a long time to get an answer.
- Information transfer takes a long time.
- Difficult coordination covering three bases or more is required.

(2) Inaccessibility to atmosphere and situation
- No information of related project development can be acsessed.
- Complicated contents cannot be transmitted.
- It is difficult to communicat with people you are not acquainted with.
- Troublesome coordination of job request.

(3) Access to shared information
- It is defficult to acsess information recorded on paper.
- It is troublesome to register and acquire resources shared on programs.

(4) Taking part in an event
- It is difficult to participate in exhibitions and public conferences.
- It is difficult to participate in events such as meetings of professional societies.
- It is difficult to learn new technology.
- A new product is often demonstrated in the center office.

(5) Business trip required
- Some jobs can be covered in a distributed business office.
- Some business trips are not successful.

2. Drawbacks of telecommunications

(1) Conference by voice transmitted by telephone
- In some time zones, many lines are busy.
- The called party cannot be caught.
- Communication by only voice results in insufficient explanation.
- Reactions of the related party cannot be indetified.

(2) FAX
- In many cases, the called fax is busy.
- Whether the message has reached the called party cannot be known.
- Transmission is not always successful and documents are sometimes difficult to read.

(3) Others
- there is not enough means to transmit his (her) comments using images and video.
- Different data forms on the computer requires troublesome conversion.

Figure 2 DISSATIFACTION/ANXIETY OF TELEWORKER

- Seldom takes part in exhibitions, seminers, and meetings of professional societies.
- Seldom knows cutting-edge technology and is prone to suffer from lowered consciousness.

[Leading teleworker]
- Not informed timely of actual development status at cntre office.
- Must make frequent business trips.
- Less stimulation makes it difficult to encourage new.
- Young teleworkers have no critical consciousness of problems.

The required environment must thus compensate for a handicap of working at teleworking offices far from the centre office. Taking on a mental role, this compensation not only allows the performance of jobs independently of the place but also provides solidarity among distributed offices.

3.3 ROLE OF INFORMAL COMMUNICATION

Taking into account only formal information such as design data and programs, the network manager is apt to build a "cost-saving" network. However, communication by persons in the same office, face to face communication plays a very important part. Informal or contextual information is needed for three reasons. The first is to complement the communication of formal information. Members of a working team need to receive information not covered by formal documents including the past processes and background information. The second reason is concerned with psychological elements. Supplying informal communication helps eliminate the separation and the mental stress that all information may not be received. The third reason is the development of engineers. In-house traning such as OJT is quite useful. Observing the job performance of a role model and learning to understand different points of view leads to unconscious development of the member.

The performance of jobs in distributed offices entails the disadvantage that such communication is difficult. The disadvantage leads to a discussion on the comparison of non-pertitioned offices and pertitioned offices. A non-pertitioned office has the advantage that everybody can understand one another by the various types of information in the office. However, work is hindered by frequent interruptions. Thus, a non-pertitioned office is

not well-suited to work requiring high concentration. In contrast, a pertitioned office makes an individual work more efficient, but it leads to other consideration for matching consciousness of individual engineers with each other. For this consciousness integration, conferences must often be held and reports must be circulated frequently. In addition, supporting space including lobbies, and common areas such as meeting rooms are needed to supplement communication.

A future issue consists in identifing what communication system is geared to a certain type of informal communication. If such information can be transmitted with well controlled, distributed offices will be an efficient environment inherited advantages of both offices.

4. COMMUNICATION SYSTEMS FOR TELEWORK

This section discusses a communication system for supporting teleworking on the basis of the above achievements of communication analysis.

4.1 COMMUNICATION SYSTEMS FOR TELEWORK

Figure 3 shows the currently available communication systems. Video conferencing system and telewriting system are such that telephone and facsimile are extended to cover conferences. The video conferencing system calls for ISDN covering 64 kbps to 384 kbps. But the telewriting system can be used over an ordinary 9.6 kbps telephone circuit. Which system is used will depend on the applicability to communication and the line cost.

The electronic mail system (E-mail) system as well has been propagated rapidly in Japan. This propagation stems from the increasing use of Japanese word processors and desktop computers. The E-mail communication system has some features not provided by other systems. Information can be accumulated, thus allowing engineers to exchange

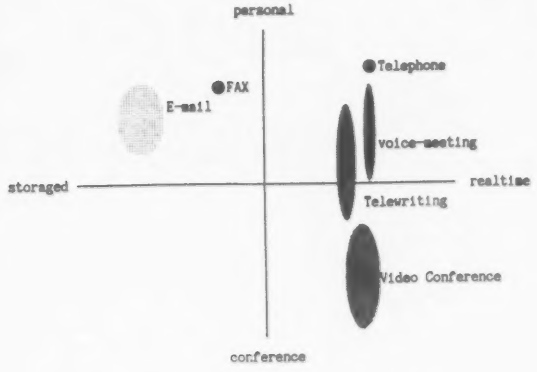

Figure 3 COMMUNICATION SYSTEMS FOR SUPPORTING TELEWORKING

their information at their leisure. Currently, there co-exist commercial base communication systems using personal computers based on telephone lines, in-company mail systems using LAN (Local Area Networks), and UNIX mail systems using by UNIX engineers. Thus, higher effects will be achieved, if mail systems can be interconnented by a mail transfer function or if an integrated user interface can be implemented.

4.2 SUGGESTION OF SUPPORT SYSTEMS FOR TELEWORK

We propose a distributed network which integrates a network transferring data for software development support tools and a network for supporting inter-office communication. Figure 4 shows the configuration of the system. Most of CASE (Computer Aided Software Engineering) tools are aimed at making it more efficient to design, manufacture, and test software, and at integrating and supporting these processes. These tools are short of the aspect that communication is supported on the basis of a development process. This field has been understood with the help of a concept of GROUPWARE or CSCW (Computer Supported Cooperative Work). The groupware deals with human interaction to support the cooperation of a business group. Sample achievements of groupware include:

- Multi media computer conferencing system that integrates voice and video at a workstation
- Common editor that allows staff members to cooperate with one another in preparing and reviewing design documents
- Computer-aided conferencing system which supports decision from discussion
- Dispay wall to support the tranmission of informal information

The new form of communication backed up by groupware technology as well as by computers and communication equipment will make the teleworking environment more comfortable.

In the future, the development of communication technologies such as a broad band ISDN will allow the supply of service which has been difficult to implement in the past owing to line speed and cost.

5. INTRODUCTION OF TELELEARNING

5.1 ENHANCEMENT OF TELEWORKER'S CAPABIRITY

The success of education depends on the growth of the consciousness of self-development. The above investigation into consciousness tells that it is important for the teleworker to master knowledge and engineering, as well as to receive stimulation and motivation. More emphasis should be put on the arrangement of a system of common lectures over distributed offices than on the performance of closed education at sites. Important is an increase in the chance for enhancing teleworker's capability through the systematization of education and training from the standpoint of integrating all sites.

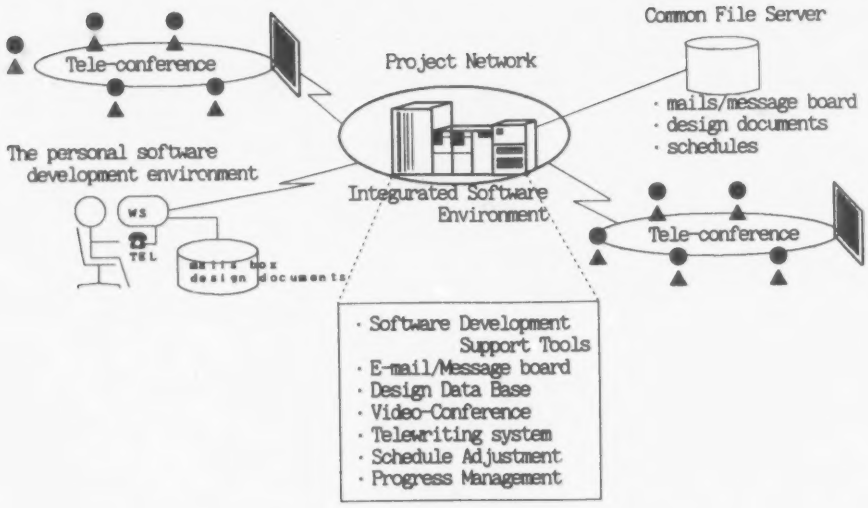

Figure 4 INTEGURATED SUPPORT ENVIRONMENT FOR TELEWORK

5.2 APPROACH TO TELELEARNING

The purpose of implementing telelearning is to carry out the education and training of a large number of people without the need to make a business trip. The telecommunication technologies has allowed remote access to an educational lecture that is held at centre office. in telelearning, the lecture need not make any business trip. Telelearning provides not only the primary effects of a lecture, but also secondry significant effects in that teleworkers are motivated and stimulated and provided with solidarity as a group working at each office.

5.3 TELELEARNING SYSTEMS

This subsection introduces training based on a video network system as an examples of telelearning and a remote CAL(Computer Assisted Learning) system.

Fujitsu has built a video network system linking distributed offices, factries and sales branches, and laboratories. The system serves various purposes including remote lecture. A lecture at a hall or studio can be listened to simultaneously at the sites by means of satellite links. The installation of a large-scale receiver consisting of a projector and the trandmission of realistic sound as if teleworkers were at the hall or studio and the capability of asking questions to the centre from the sites are essential for this system.

The remote CAL system is superior to the standalone system in that exercises to be supplied can be changed flexibly to the level of an individual learner. The remote CAL system does not supply learning materials in the form of floppy disk, different from the standalone CAL system, but delivers them directly over an ISDN line. Collecting results of learning by users allows effects to be fed back to the learner and the learning material developer. A large-capacity disk at the centre computer and high-speed transfer by ISDN have allowed the timely supply of coursewear and new learning materials.

5.4 TELELEARNING USING DISTRIBUTED DEVELOPMENT ENVIRONMENT

We suggest telelearning based on a network environment for distributed software development. It intergrates a telewriting system for a remote conference, a video-conferenceing system, and desktop workstations connected over a network.

The proposed system allows communicative learning via one workstation assigned to each teleworker, and lectures and training based on a video-conferencing systems. Figure 5 shows a system image to be implemented.

The following are the requirements for implementing this systems:

Object of telelearning
: Identification on whether or not telelearning is geared to the object.

Operabirity
: It is desirable that special operations not be needed.

Bidirectivity
: Features including automatic answering should ease the burden on the manager and supply of a system accumulation questions as well as accommodating online anawering.

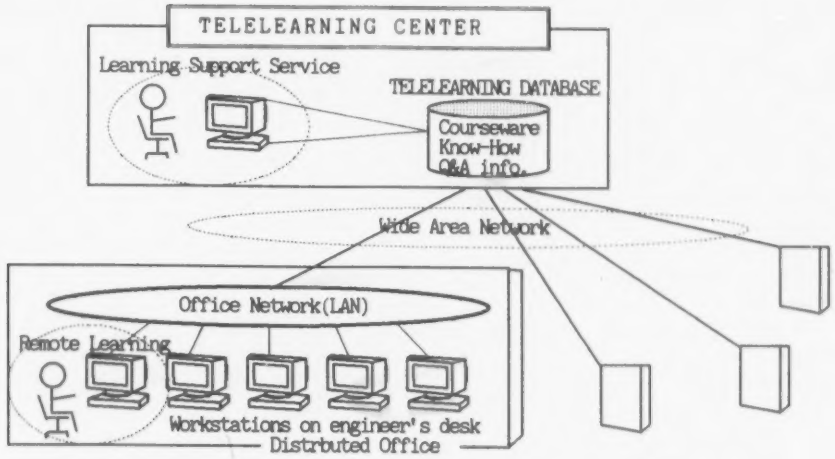

Figure 5 TELELEARNING UTILIZING DISTRIBUTED DEVELOPMENT ENVIRONMENT

Motivation and stimulation of learner
The telelearning with the level and at an appropriate pace of each teleworker, and promotion of making human relationships through communications among learners.

Protection of privacy of learner
The results and records of telelearning must be handled confidentially.

Evaluation of effects
Achievements must be evaluated qualitatively and quantitatively.

6. SUMMARY AND FUTURE ISSUES

Undoubtly, business offices will be distributed slowly but steadily. It will become a essential technology in the future to develop the software with distribution. The rapid progress of distibution calls for supporting of informal communication between distributed offices and the facilities which allows teleworker's capability to be enhanced.

The advent of a new telecommunication service provided possibly by broad hand ISDN in the future will lead to the implementation of diverse telecommunication systems supporting teleworking. Recently, a commuter train without seats introduced on trial in Tokyo has been used to relieve congestion during rush hour. Incidents of handling commuters as cargoes has been reported on the TV news. It has posed a human mental problem that cannot be solved using only efficiency and utility. A future highly adovanced telecommunication system must be able to deal with human paychological aspects including human-machine interface.

TELECOMMUNICATIONS, INFORMATION TECHNOLOGY AND THE NEW ORGANIZATION -- AND YOU

John Spence
John A.Spence & Associates
Sydney, Australia

ABSTRACT

Telecommunications and IT are having profound effects on the nature and shape of organizations. There are already certain indications of what lies ahead -- including people's roles in the changes. The paper explores these issues and outlines directions to pursue to influence organizational destinies.

1. INTRODUCTION

Organizations and their structures are undergoing significant change under the impact of information technology. They have always needed to respond to such influences. But the effects of telecommunications and computers are proving so far-reaching that we can expect major shifts in business, government and related institutions in the future across areas that will affect us all. And those who plan for this will cope best with customers, competition and community demands -- and their own careers.

Just what will happen will depend not only on the vagaries of the future but also on which organization and which area. Indeed there is a need, as in this paper, to consider many diverse developments so as to appreciate what is happening and which indicators of future directions we all should be watching.

2. WHAT INFLUENCES?

What organizational influences are we talking about? One of the earliest and most significant was the telephone. With that one development whole new ways were created for linking people and organizations together. Messengers were suddenly not needed; travel could be reduced; and it became possible for activities to move away from the one site i.e. to be decentralised as never before.

Information also began to move at unprecedented speeds. Theoretically so did decisionmaking -- although this "immediate" information encouraged top managements to get involved in the decision process where previously greater delegated authority had been necessary to keep things going.

And now in the nineties, in addition to communicating ideas verbally, we can do such things as complete financial and document transactions electronically, view drawings and diagrams at a distance via facsimile, and even see people as we talk with them by phone or teleconferencing facilities.

These and other technological developments represent truly dramatic shifts in the way organizations work, with the power to alter their whole rationale.

3. THE DEVELOPMENT OF ORGANIZATIONS

The benefits of harnessing individuals into an organization's integrated, coordinated force have long been recognised. Yet managing this "leverage" of individual contributions -- the science of management as we know it -- is less than 200 years old. This is even though organizations, like the "organisms" the name implies, have had to adjust as the environment has altered (due to the forces of new people, practices and pressures).

While many would argue we still have much to understand about how to make organizations effective, much *has* been learned. Very significantly, managers and owners have begun to recognise how integrating new technologies can form a key part of this process. And they realise that there are windows of opportunity -- windows which can close if a competitor moves first.

753

4. KEY IT AREAS AND THEIR INFLUENCES

4.1 THE SCOPE OF INFLUENCE

Four prime reasons have been suggesed for using information technology as a strategic resource. These are:

* to gain competitive advantage;
* to improve productivity and performance;
* to open up new ways of managing and organising; and
* to develop new businesses.

In 1992 the distinctions between these are becoming less clear. Moreover, there seem to be endless possibilities for using computers and technology to achieve them-- with their success greatly influenced by management's acceptance of IT. In this paper then, rather than attempt to canvass all areas, some of the more significant are reviewed to indicate future organizational directions.

4.2 COMPETITION AND COMPETITIVE ADVANTAGE

IT can be used to increase competitive advantage and even to change the competitive environment, such as by:

* changing industry structure;

* influencing buyers and suppliers;

* creating new products and markets; and

* interpreting "process" information.

A classic example of changes to industry structure was in the printing industry not long ago, when Rupert Murdoch -- taking the idea from Eddie Shah of the newspaper *Today* -- fought the unions and won the battle for electronic typesetting. That new mode of working dramatically altered the production and distribution of newspapers -- and changed forever their labour forces and organizations.

Customer behaviour has been markedly influenced through IT -- a familiar example being the airline (and other) reservation systems. The ease and versatility of these systems encourage customers to keep returning to the same travel agents. The latter in turn tend to utilise those airlines (and hotels/motels) whose systems they have and to adjust their sales and marketing organizations accordingly.

New products and markets resulting from IT also appear constantly, necessitating new organizational approaches for their effective introduction. One of the most interesting of these -- and one, as yet, far from fully exploited -- is the "Smartcard". Its potential for handling transactions without accessing central computers is already impacting on traditional processes and functions.

Then there is the imminent influence of IT's ability to monitor, analyse and learn from "new" information . By evaluating the data constantly being generated, new approaches to managing and organizing are emerging which will change functions and relationships.

In other words, through its innovative application and its ability to gather and interpret new information, IT is changing the competitive environment and the shape of organizations in it.

4.3 DECENTRALISATION AND GLOBAL DEVELOPMENTS

One of the strongest messages from the 1991 Telecom Forum in Geneva concerned the big push to globalisation. The hype of recent years is turning into reality as managements find they have not only to decentralise further but also to link with others (even competitors) to form associations in order to meet the needs of today's and tomorrow's communities and markets.

Telecommunications and computers have been both the cause and effect of this phenomenon. They offer competitors access to better, lower cost sources; and customers the freedom to shop internationally. At the same time they they provide the means for managements to establish global frameworks and operate them, even round the clock.

As mentioned earlier, this all began with the telephone. But nowadays organizational flexibility and freedom are also shaped by by radio and satellite services as well as computers, modems and facsimile machines. Office complexes have become the organizational nerve centres and, at the same time, technology has extended the geographic reach of

individuals and firms -- enabling production and service activities to be handled at great distances from each other and from the centre, nationally and internationally.

One very significant outcome of these developments has been the emergence of the truly international organization. There is no longer a need for an enterprise always to be headquartered in its country of origin. Just as there now are widescale international arrangements for taxation and for the most economic sourcing of materials and labour, there are now grounds for locating the "head office" where communications services, reliability and tariffs dictate. In effect a very different form of corporate structure has been created by telecommunications and computers.

4.4 ORGANIZATIONAL RESOURCES

Much of IT's *publicised* contribution to manpower in organizations has been to reduce both workload and numbers, hence cutting costs and increasing cost effectiveness. And this has certainly affected business and government and their structures.

In addition, however, there are two other manpower-related roles for IT which should be included in any thinking on organizational impact.

The first of these is "telework": an arrangement whereby, through the use of telecommunications and terminals, people are able to participate in an organization's activities at a distance.

Telework permits the creative worker -- e.g. software developers, writers, designers and programmers -- to work in remote environments which can stimulate their talents. This encourages better output and saves the managerial and financial stresses of accommodating these people.

Another benefit to the organization has been that telework makes temporary labour readily accessible. Such access to resources as and when needed is not only effective but keeps the permanent organization pared down to its best fighting weight.

Thirdly, telework allows organizations to retain key skills by stimulating their interest and offering greater job flexibility, and to access others who might not otherwise be available. Centres established at a distance fom the main office can save people their valuable commuting time -- requiring more decentralised management but at the same time retaining valuable staff who might otherwise go elsewhere. Very importantly, telework provides the means for managements, if they have the ability and systems to handle it, to access staff from anywhere in the world at whatever time of day or year. Managements are already applying this concept to handle offshore data processing and program development. But it has far greater potential, with great organizational implications.

The second IT manpower-related role to mention is that of "expert systems" (or, as some prefer, "knowledge-based systems" and part of the Artificial Intelligence family). These are computer programs designed to contain the in-built knowledge of experienced people, the "experts", for access by others via terminals -- and via telecommunications links where remote access is needed).

While expert systems are still largely at the experimental stage and a long way from being in wide usage, they already indicate where organizations are headed. Their promise is that they will allow complex tasks to be handled by less experienced staff -- thereby effectively reducing the skill requirements for many roles.

4.5 COMMUNICATIONS

Organizations used to require that their people could be actually seen whenever needed. Obviously moves to decentralise and internationalise have meant a radical rethinking of that requirement. Nevertheless there are still cultures where "seeing" the person is important; and in these environments the recent introduction of reasonably priced videophones and videoconferencing facilities is beginning to increase management's "comfort" -- and accordingly raise their interest in decentralised and international activity and structure.

Satellites are also changing how executives manage distant activities. VSATs (small satellite terminals) now make contact with remote centres where telecommunications infrastructures are inadequate. They are also being used

to provide automatic access to distant data. Moreover satellite photography is offering the means of assessing the resource potential of remote regions; and the latest satellite geolocational services are opening up totally new approaches for the precise control of physical distribution systems. These different developments represent the means for eliminating positions and even whole organizational layers.

4.6 CHANGES IN MANUFACTURING

While office systems often seem to get the most publicity, the results have been arguably at least as great in manufacturing where the machine tool has been elevated, via IT, to a highly precise, programmable device.

This move has changed forever the economics of the production unit and its owner. It has made it possible to move into "flexible manufacturing" with completely different cost and operational structures. Short runs have become economic to handle, with costly and time consuming set-up times being cut dramatically. One person can now supervise sizeable batches of machines. Importantly, functions like design and production can be far apart -- even in different countries -- being linked via telecommunications.

These changes have meant significant alterations to past practice; and the world is finding that organizations now need people with very different perspectives who are able to handle the demands of increased precision, detail and integration. Experience in America in adopting new IT approaches led to the observation that traditional management attitudes, involving top-down decision making, piecemeal changes, and a "bottom-line" mentality, are incompatible with the requirements and unique capabilities of advanced manufacturing systems.

So these new technologies are also tending to bring about changes in organizational culture and behaviour as well as in structure.

5. EXPERTS' VIEWS OF TOMORROW'S ORGANIZATION

5.1 FORECASTS FOR THE 80S

Back in 1958, Harold J.Leavitt and Thomas L.Whisler predicted what organisations would be like 30 years later, largely as a result of IT.

Their view was that:

* middle management would be thinned down and given responsibilities that were more completely defined and lower paid;
* top managements would concentrate more on innovation and strategic direction and less on day-to-day; and
* there would be a tendency for large organizations to recentralise.

As the end of the eighties approached, these patterns began to appear. Now into the nineties we are seeing strong pressure for leaner, better focused organizations (with some moves to recentralisation, although as yet with a lesser emphasis than they forecast).

5.2 LOOKING TO THE FUTURE

The ever growing power and financial attractiveness of IT certainly seem to offer the possibilities for new types of organization and structure.

Some analysts expect that automated information and communication networks will support information sharing through large, widely dispersed, complex companies, making them as tightly connected as the small ones.

This suggests that large entities, whether governmental or private, will have the potential to be as flexible as small operations -- with all the analytical tools, databases and international affiliations to handle their needs. This may be so. But experience indicates that they will also need to take other action to succeed, including particularly dispensing with functions which are unnecessary or uneconomic.

It seems, most significantly, that we are moving into a time where managements truly will need to manage as never before. Technology of itself will not guarantee competitiveness. In fact with its trends are towards increased specialisation, managers will suddenly have to be better coordinators and motivators rather than industry "experts". Also, to be sufficiently forward thinking to be competitive, they will need to realise that the future lies in learning to use this technology to process "information" and not just "data".

Most people's emphasis has been on using IT to do faster what one did before. But when moves from data to information are made, there emerge totally different approaches to delegation and organizational form.

This is primarily because most organizational layers neither make decisions nor lead. They simply "process" data -- something which computers and telecommunications facilities are ideally suited to do with minimal human intervention.

The logical consequence for the information-based organization is a flatter structure -- one more closely resembling that of a century ago than today's. But to make this work will require, as Peter Drucker observes: "greater self-discipline and even greater emphasis on individual responsibility for relationships and communications".

So organizations pursuing this course will have many differences from those of today; and certainly from the 1950s model which used to be the reference.

6. WHAT DOES THIS ALL MEAN FOR THE ORGANIZATION -- AND YOU?

6.1 THE CHANGING HIERARCHIES

From their military beginnings, organizational structures have been founded on hierarchies, with tiered levels of authority from top down.

Often such hierarchies are criticised for bureaucratic slowness and stifling of initiative. However, research has found that they actually represent a very sound structure basis to release energy and creativity, rationalize performance and improve morale. Also it seems that the structure levels are related to role complexity. With IT enabling the management of greater complexity, the result is a need for fewer levels.

6.2 THE NEW DIRECTIONS

But what does all this imply for the organization and for us?

First, telecommunications and computers will mean completely new and totally different types of ventures. The opportunities are there for any of us with vision to start innovative "information" oriented activities, like SWIFT, the banking transactions marvel -- now very familiar, but quite revolutionary on first appearance. Those with the right entrepreneurial talents should benefit wonderfully from this technology.

Secondly information technology will lead to cuts in organizational positions or strata. Organizations will be flatter, with clear and more specialised job descriptions and using telecommunications for the critical management links. In turn, those who anticipate this development will be best placed to influence the shape and direction of their own areas.

Next telecommunications and computers will enable organizations to benefit from, and adjust their structures towards, internal network utilization -- where the inputs from selected people can be encouraged to stimulate improved performance. Those familiar with the processes will become network members, in a position to influence their organizations and managements.

Then there will be greater recognition of the "psychological" gains from tele-linked people, when organizations open up their communications and structure to a very different tele-worked form of inter-connection. That may be a distant horizon for the more conservative organization. However it is distinctly and imminently available to those who trust, and build trust in, their people and who listen to others' views. This may, in fact, be the most exciting and rewarding of all the IT futures -- justifying participation by those of you who have the interest and drive to win support.

7. CONCLUSIONS

Telecommunications and computers will play a pivotal role in all these developments. However, like the new applications which will emerge, the new organizations will depend finally on the people who design and run them.

The opportunities now are clearly very exciting. The final outcomes, whether in academia, business or government, will reflect some or all of the directions outlined here. But very significantly they will also, as never before, be open to influence by you, the participants.

Learning in the Imagination Age: The Student as Network Citizen

Rick Withers and David Porter
Education Technology Centre of British Columbia
Sidney, B.C., Canada

Abstract

Technology has the capability to greatly enhance the quality of classroom learning, with its power to reach out around the world and connect students with mentors, information services, and other learners. The Education Technology Centre of British Columbia is currently prototyping an information services network for schools designed to make British Columbia students true "network citizens".

INFORMATION TECHNOLOGY AND SCHOOL RESTRUCTURING

A 1989 Royal Commission report on education in the province of British Columbia, Canada, and a subsequent review of the education system by the Ministry of Education, produced a policy framework for the future outlined in three key documents: *Policy Directions, Mandate for the School System, Year 2000: A Framework for Learning*..

The central tenets of B.C. education reform, with regard to teaching and learning, and as outlined in the *Year 2000* documents are to:

- refocus the system to meet the individual learning needs of students through personalized, self-paced learning activities, and ensure the development of skills needed for productive life in the Information Age; and to
- facilitate a change in the teacher's role from information provider to learning mentor, and in the student's role from information receiver to knowledge builder.

Current efforts at school reform and restructuring of education aim towards changing what the education system does, not simply improving what it is already doing. While many important individual reforms are aimed towards changing what happens in classrooms, the more general thrust is towards restructuring the overall educational system to make it more functional for and responsive to needs of lifelong learners in the Information Age. The strategic importance of an educational data network in implementing *Year 2000* goals and objectives cannot be over-emphasized.

Establishing new education information networks for the school system, and the home, will lead to changes in the nature of schooling, and the roles of teachers, learners and administrators. Used wisely, the new information technologies can be used to support active learning, rather than passive reception of information by learners, and they can be used to support cooperative learning. These key principles are found in the B.C. government's *Policy Directions* and *Year 2000*.

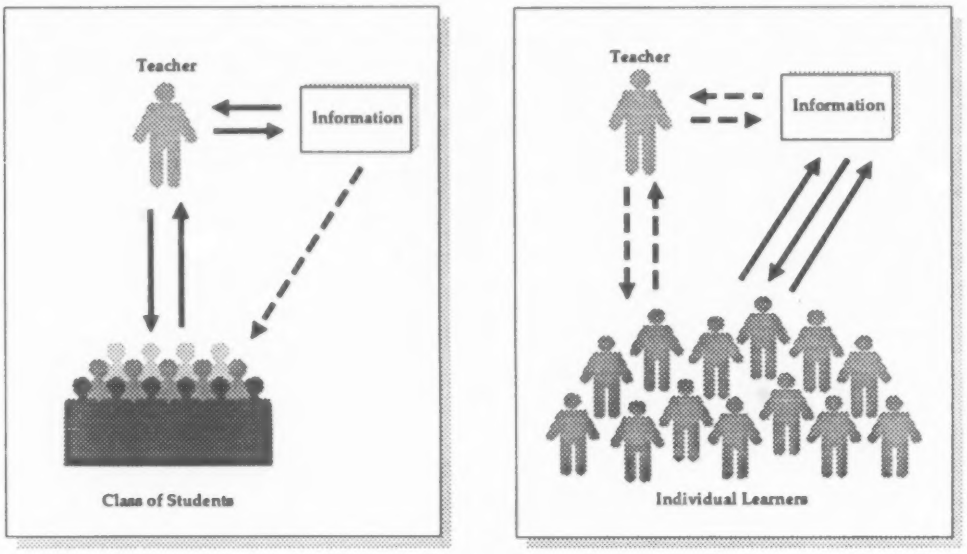

Figure 1
CHANGING PARADIGMS: FROM INFORMATION RECEIVER TO KNOWLEDGE BUILDER

THE BRITISH COLUMBIA EXPERIENCE

In May 1990, The Education Technology Centre of B.C., in cooperation with 11 school districts in the Southern Interior of British Columbia formed a consortium to prototype an information services networked designed to meet *Year 2000* education principles. Along with corporate partners, Digital Equipment Corporation of Canada, the B.C. Tel Group, B.C. Systems Corporation, the Ministry of Education and the Faculty of Education at Simon Fraser University, ETC launched the Southern Interior Telecommunications Project (SITP).

Based on recent experience with the Southern Interior Telecommunications Project, learning networks promote active student participation in the learning process, and support cooperative learning strategies involving small and large learning groups. Students in the pilot have access to a wide array of information services and databases providing up-to-date learning resources for use in the development of student

knowledge in Social Studies, Science and other areas of the curriculum. In carrying out their learning, students develop skills in navigating through large databases, evaluating which bodies of information are useful and those that are not, and in linking data drawn from diverse databases – skills that are beginning to define a new kind of literacy.

Learning involves the "construction" of knowledge. That is, learners must give meaning to new information and experiences by incorporating them into their personal frameworks for understanding the world. Research shows clearly that learning requires the active participation of the learner, and that learners must be given opportunities to reflect upon their learning experiences in order for successful learning to take place. An integral part of this reflection process is sharing one's ideas and comparing them with the ideas of others. We also know that individuals learn at different rates, and have different preferred learning styles. Learning materials and teaching approaches must therefore allow for different pacing and must make it possible for learners to explore information in a variety of ways and in a variety of individual and group settings. An education information network supports both individualized learning and collaboration among students and educators.

The role of the teacher changes in schools where information is easy to access. Teachers in these schools do not see themselves as being primarily responsible for packaging and delivering information to students, which is then tested at a later date. Rather, they view themselves as mentors who are responsible for supporting students in the development of independent learning skills, skills that are required to access, synthesize, and evaluate large, and often conflicting, bodies of information. These changes reflect many of the underlying goals of the *Year 2000* document.

In summary:

- Technology has the potential to transform the relationships between teachers and students and even to change what schools look like. The notion of network citizenship for students, teachers and school administrators is realizable.

- Students will be required to work collaboratively on projects, as well as alone. Telecommunications will be an enabling technology, allowing students not only to work collaboratively, but independent of time and space.

- Information literacy will be emphasized; that is, students must be able to locate, retrieve, synthesize and interpret information.

NETWORK CITIZENSHIP

In order that students, teachers and administrators are able to access and exchange information they must become network citizens. Fundamental to the notion of network citizenship is the recognition that information resources should be kept as close to the users as is possible. This means that information can be stored at the

workstation, school, district, regional, provincial, national or international level (via the Internet), as appropriate.

The Student as Network Citizen graphically illustrates this concept. (Figure 2)

The Network Citizenship model is the metaphor for the emerging information services network which is being designed for British Columbia schools.

As such the model drives:

- network design,
- information providers, and
- interface providers

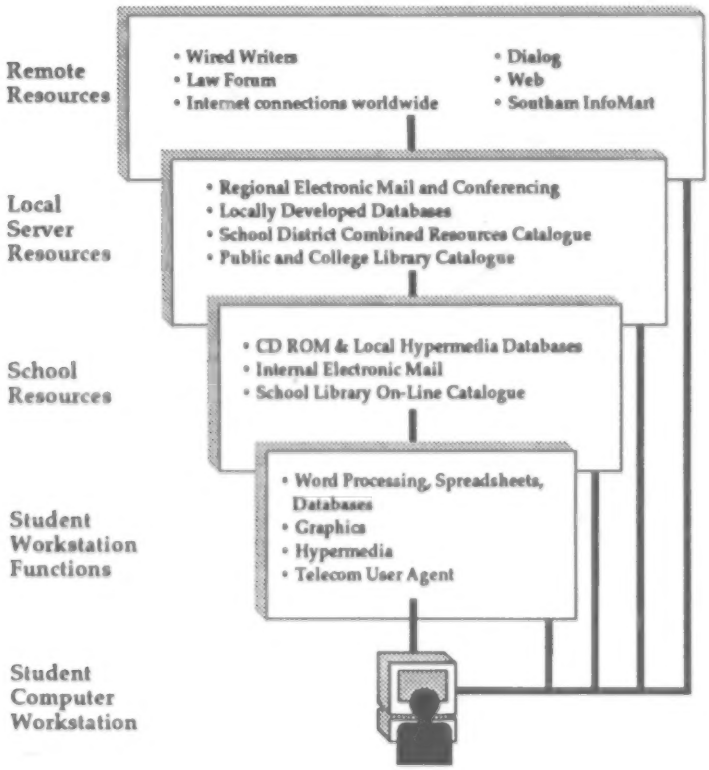

Figure 2
THE STUDENT AS NETWORK CITIZEN

A THREE-TIER NETWORK DESIGN

To connect all 75 school district offices and 1900 schools into a single, homogeneous provincial network, a three-tiered network structure is proposed as described below.

A backbone network, roughly equivalent to a network node in each school district office is envisioned.

Individual districts will then create their own district level networks according to individual needs, but subject to overriding provincial standards.

Local Area Network (LANs) at the individual school (or district) level will be connected to District Wide Area Networks (WANs). Once again, in order to connect to a district and/or provincial WAN, local LANs must comply with provincial standards, defined later in this document.

NON-INSTRUCTIONAL FACTORS AFFECTING THE TELECOMMUNICATIONS REQUIREMENTS OF THE BRITISH COLUMBIA EDUCATION SYSTEM

The previous sections of this paper have focussed on the educational rationale, needs, applications, development and support requirements of communication and information services. This final section will discuss many of the unique factors affecting the planning and strategies related to the development of a provincial education telecom-munications network for British Columbia.

There are many factors which affect the awareness, demand, and support for a provincial education network. These factors in turn affect the design, development, and implementation strategies for such a network. Many of these factors are atypical of situations in business and industry, and an appreciation of these factors is essential in understanding the provincial directions and plans in this domain. These factors are described below.

- Geography & Demography

B.C. is geographically immense and sparsely populated. The large majority of the province is mountainous, making access difficult. A large percentage of the population is based in the southwest region of the province, with the remainder distributed among a large number of small, dispersed communities. The location of these population centers could be best described as analogous to a star-topology highway system.

B.C. covers 950,000 square kilometers, roughly 2.5 times the size of Japan. However, the population is only 3 million, compared to 125 million in Japan. In addition, over 70 percent of the population is concentrated in a region representing 3 percent of the province's area. All of these factors present challenges in the development of a cost-effective telecommunications infrastructure In addition, the heavy concentration in a small region creates challenges in ensuring equity of access to all forms of resources, especially electronic information services.

- Education system organization

B.C.'s education system includes a central Ministry of Education, responsible for funding, policy, and curriculum development. The province includes 75 locally-operated school districts, with responsibility for local education program delivery and operations, each governed by

a locally-elected Board of School Trustees. This organization creates perpetual struggles over centralized versus decentralized control of programs and financial resources. Thus, the consensus-building process related to the need for an enterprise-wide network for the education system is affected by issues of mutual trust and autonomy. No single body is individually capable of providing the financial and human resources necessary to commit to the implementation of such a network.

These student population range of the 75 school districts ranges from 700 to 55,000 students, with a total of 530,000 students attending 1600 schools in the public education system (average school size of 330 students). An additional 35,000 students attend one of 300 autonomous independent schools (average school size of 100 students). Thus, a wide range of organizational and management structures exists in the B.C. school system. Thus, a common suite of communication and information services is considered of less value than might be expected.

- Educational information technology usage

The use of microcomputers and related information technology in B.C. schools has been a grass roots movement, with most acquisition and utilization decisions being ad hoc, locally idiosyncratic, and virtually devoid of large-scale formal consideration of standards. Fortunately, B.C. has been blessed with a large group of committed, innovative educators who have frequently been leaders in setting global directions related to education applications of technology. This grass roots movement has resulted in a significant installed base of microcomputers in classrooms, libraries, and laboratories. Recent surveys estimate approximately 46,000 computers servicing 565,000 students and 38,000 educators, yielding a student-to-computer ratio of approximately 12 to 1. However, an enormous range of priorities and access policies exist in individual schools, resulting in little province-wide consistency in how information technology is used to support the educational activities of the system.

Several de facto standards for workstations and LANs have developed, and the Ministry of Education has recently identified a set of common standards which reflect the extant situation. However, given the cost-sensitive, time-dependent nature of capital expenditures in public education, it is estimated that only a third of the existing technology is likely to meet emerging workstation and networkability standards, resulting in a large group of "legacy systems", most of which are non-expandable, stand-alone workstations. This technology must be recognized in the planning process, but is likely to be of only modest transitional value in the network implementation process.

Those school-based workstations which are likely to meet networkability standards include an approximately equivalent number of Macintosh and Windows-capable MS-DOS machines. Common LANs include AppleShare and MacJanet (running over AppleTalk and EtherTalk), and Novell NetWare (running over Token Ring and ArcNet).

- Extant government and education system communication networks

The vast majority of B.C. provincial government information processing and networking services are provided by the

B.C. Systems Corporation (BCSC), a semi-autonomous Crown Corporation. The distributed nature of B.C. government operations has resulted in a network which reaches a surprisingly large number of moderately-sized communities, albeit with relatively low bandwidth best capable of supporting text and data applications.. Current planning for a provincial education network is concentrating on the viability of the existing BCSC network as a provincial backbone carrier.

Education is the only industry in which most professionals do not have easy access to voice and data communications. Few schools have extensive phone systems reaching beyond a small number of locals, and even fewer have access to dialup or dedicated data services. The cost and breadth of access to regulated public packet-switched networks has negatively impacted this situation.

- Education's cost-sensitive approach to service provision

Public education has been, and will continue to be very cost-sensitive, and generally incapable of supporting unpredictable, usage-sensitive costs. Thus, it is essential that predictable, flat-rated network development and operations, as well as services, be considered wherever practical. Public domain software should receive strong consideration. Large-scale licensing of a suite of information services will likely need to be negotiated. Client-server models for e-mail, conference participation and database / information service search & retrieval are critical, since they minimize on-line, usage-sensitive costs, and make these more predictable on a large scale. Client-server applications also minimize network loads, increasing the utility of relatively low-bandwidth network services.

- Education system experience, training, and support requirements

While a strong cadre of experienced, technology-supportive educators exist in the B.C. system, the majority of educators have limited experience with technology, usually within a narrow range of applications. Most educators would be considered technology-neutral or technology-apprehensive. Currently, only a modest minority of educators believe that technology can and should play a mission-critical role in supporting the educational reform process. Most currently consider technology to be "add-on" rather than integrative. Finally, most educators are sporadic users of technology, thus lacking the regular usage patterns that develop generalizable skills and the problem-solving experimental approach necessary for successful use of a range of software applications.

This educator experience situation results in a desire for stable, consistent operating environments. Unfortunately, telecommunication-based services are generally immature technologies, with evolving standards, products, and network access protocols. It is not surprising that many educators consider these services to be "bleeding edge", fraught with startup and support frustrations that are more difficult to resolve in a distributed set of autonomous school districts than would be the case in most business and industry environments.

Educators have limited access to and financial support for technology-related professional training programs. The breadth of experience, technologies, and applications make broad-scale training difficult to offer and generally less-than-effective. Rarely, if ever, is technology training mandated. The most effective technology training in

education is self-directed by individuals who are able to analyze their training requirements and to build a personal program to fulfill those needs. Thus, most effective training is needs-driven, on-the-job, intrinsically-motivated, and individualized.

This experience and training situation accentuates the need for intuitive, self-documented, customizable, graphical user interfaces (GUIs), consistently implemented to support a variety of applications. While these applications exist in many application domains, they are only now becoming more widely available for telecommunication-based services

- Standards??

In general, the education system employs very few information systems professionals. Similarly, IS consultants are not commonly contracted to analyze and recommend solutions for educational environments. This results in a situation where much of the decision-making authority lies in the hands of senior school district management who do not have the necessary support to make informed decisions related to strategic planning for critical technologies, including local and wide-area networks. This, in turn, provides opportunities for hardware and software vendors to offer attractive products which may provide short-term solutions, but which may not support long-term goals and directions.

This problem is especially evident in the telecommunications and networking domains. Little recognition or understanding of standards exists in school systems, and this is a significant impediment to building commitment towards a long-term, enterprise-wide networking strategy. Most education decision-makers fail to recognize the critical nature of an "open systems" approach to standards definition, product and service selection. This also makes it difficult for education systems to develop transitional strategies that recognize industry-leading de facto standards. Given the complex nature of a standards-based strategy, there is some question whether the B.C. education system (and likely most others) are currently able to understand and support this approach.

CONCLUSION

The potential for telecommunications-based services in education is only now being realized. Many exciting applications are being developed and validated. However, the public education system faces many challenges related to clear, consensus education rationales, effective support and training, education-specific applications development, organization and management structures. It is expected that potential solutions to these challenges will be developed and evaluated over the next few years to ensure that the education system has some control over its destiny in the quest to develop mission-critical, enterprise-wide communications and information networks.

ISDN APPLICATIONS...?
IT DEPENDS...!!!

Charles Cranford
Telecommunications Research Associates
St. Marys, Kansas U.S.A.

1. ABSTRACT

Unless vendors and end users step up to some "agreements" being formulated, ISDN will do considerably less than it could otherwise. The value of ISDN applications will be perceived differently by various companies. However, it is a fact that some companies are installing ISDN today and reaping benefits based on their individual needs. The purpose of this paper is to examine what normal steps this technology will have to follow for broad acceptance, which steps is it already in the middle of, and, most importantly, what critical steps remain for the marketplace "pull" to take over the vendor "push" of today.

The first step for our analysis is the native search for applications, which any new technology will have to conduct. Applications, in the ISDN world, are spelled S-O-F-T-W-A-R-E, which will be the life-blood to this technology. Software lives in three major locations today: 1), in the IEC or LEC switch which is connected via the Primary Rate Interface to the client's large CPE; 2), in the LEC or PBX switch which provides services to the client's desktop; and, 3), in the PBX, on the trunk side, providing networking features between PBXs. Today the three driving applications, which by themselves cost-justify the technology decisions, are: 1), Telemarketing Group Enhancements; 2), Analog Key System Replacement; and, 3), Enhanced PBX Networking. The three software locations and applications listings coincide, as we will see below, and have gotten varying amounts of publicity.

1) The most celebrated application is the Primary Rate Interface delivery of the calling telephone number (Automatic Number Identification, or ANI) on an 800-Service number to a telemarketing group. How much of a value this capability is to an organization can be measured by the question: What would you do if you knew what number was calling BEFORE you picked up the call? The delivery of ANI has reportedly saved telemarketing agents from 4-20 seconds per call (It Depends...). Although this seems to be a small amount of time, one company that we surveyed managed to convert these "seconds" to over 400 hours of 800-Service billed time saved. But that's only part of the equation for the telemarketing manager.

Besides saving agent time and salary, the telemarketing world now has a second question to measure ANI's value: What would you do if the Average Call Holding Time was decreased? When reviewing the issues of Agent Billed Time, Number of Calls Handled, and Level of Customer Service we see once again the answer is very individual (It Depends...). Some clients will want to reduce agent expenses (not numbers of agents, though), while others will want to increase the number of calls Handled, while still others will want to keep the number of agents and calls constant but differentiate their operations by providing higher levels of customer service. As subjective as these issues are, clients are installing ISDN for real benefits to their bottom line - today.

2) The Basic Interface's most celebrated application is Analog Key System Replacement. Many clients today that own an analog system are looking at ways to improve services at the user's desktop. In the past, services were invoked with a combination of Touch-Tone signals and switchhook flashes (hopefully done at the right time for the correct amount of time). Many of us have seen telephone sets with the faceplate that describes how to invoke a service with the "*" plus a number code, while the cancellation of the service (or invoking another service) might be brought about with the "#" plus the same number code. Pre-ISDN clients that wanted higher feature/functionality had few options outside of purchasing a PBX with a proprietary signaling protocol. This, of course, required the client to purchase subsequent higher feature/functionality CPE from the original vendor. The Basic Interface recommendations (followed by the emerging National ISDN-1 specifications) now allow clients a choice.

Clients that have Basic Interface service from a Telephone Company Central Office have approximately a dozen different vendors from whom they may purchase CPE. The most flexible of these are the Personal Computer Terminal Adapters (PCTAs).

Using software to load both the standardized signaling messages and the vendor-specific extensions of the protocol, PCTAs can support high feature/functionality enhancements to analog telephone service at the desktop. Software in the PCs can emulate more expensive telephone sets and features can be invoked using the keyboard of the computer.

3) The third driving application is loading ISDN networking software on the PBX at a client's location and connecting it either to a second PBX via a private facility, or to a Private Virtual Network using a leased- or switched-facility. In the beginning days of this application the benefits appear to be small, if any. This software does NOT usually provide enhancements to proprietary networking capabilities that exist between PBXs made by the same manufacturer. It does, however, provide a platform for interworking between different manufacturers' PBXs.

Work on standards for communicating between different manufacturers' PBXs has been painstakingly slow. However, the Q.931 signaling messages, and vendor-specific extensions, can be loaded onto an IEC or LEC toll/tandem switch which can act both as a switch and an interpreter. Inter-switch services utilizing the standard signaling messages will be switched normally while the vendor-specific extensions can be translated or "mapped" from the originating vendor's coding to the terminating vendor's coding. The set of services that are supported today are VERY small, but the more important direction of inter-vendor interoperability gives us hope for future enhancements.

Other applications in the ISDN world that are less aggressively sought-out include several voice-only and voice/data capabilities. Data-only applications are not as abundant, but this is probably due to a wide range of open, pre-ISDN protocols that were already integrated into the market.

The second step of our analysis is what steps has ISDN already taken, and how does this infrastructure help it to grow? In networking, this infrastructure is spelled Signaling System Number 7 (SS7) and its job is to take us out of "Island ISDN" and into "Ubiquitious ISDN". The SS7 protocol is implemented between the network switches and the Signal Transfer Points which quickly relays the messages to the next switch. Not only does SS7 enable faster call setup, but the ISDN User Part (ISUP) carries a mapping of the Q.931 Signaling Message Information Elements that allow services to be passed between ISDN-capable switches. However, to implement this capability nation-wide, there is a considerable investment that has to occur in software, network facilities, and hardware.

The biggest investment in hardware that has to be installed by all the LECs is the Signal Transfer Point. These fully redundant, high-speed, high-reliable (most of the time), high-dollar machines are sold in mated pairs and installed in different parts of the service area (so that catastrophic disasters do not take down the whole signaling network).

Network facilities have been specified as running 4800 bps (analog) up to 56/64 Kbps (DDS or DSO in a DS1). These links (lettered A-link through F-link depending on what they connect) are usually duplicated so that there are two links between any two pieces of network equipment. These links are both active (one SS7 myth is that they are active/standby) and load share traffic between network "signaling points", however ALL the messages for a single call are carried on the same links for the life of the call.

Software "packages" are installed depending upon the services offered by the network. The two main packages that we need to carry our ISDN signaling messages are Message Transfer Part (which finds the path through the network) and ISDN User Part (which carries the mapping of the Q.931 signaling message).

The next major issue is how we will pass SS7 capabilities between the IECs and the LECs. This capability, named Network Interconnect, is a very hot subject among users and providers today. The main technical issue is how do we pass needed information from one carrier to another (ANI), and keep proprietary information (billing records, network configurations, etc.) guarded. Certain "firewalls" needed to be constructed for the allowances/protections and most of the technical work beyond that has either been decided or is well under way. Business issues, though, will still have to be worked out.

The biggest business issue in the public eye right now is revenue sharing for delivery of ANI. If the customer is billed one or two cents per delivery of ANI who gets how much of that revenue? The IEC will claim that they are entitled to it due to the Feature Group D tariffs that they pay. The LECs will want their "fair share" for the ANI origination or delivery. Where ideas

712

for solutions are all over the board, one of the most interesting to this author is the idea that the IEC "gives away"

ANI to the LEC in hopes of stimulating more calling over the network (similar to the marketing idea of giving away razors to help sell razor blades).

However the issues are resolved, the infrastructure of SS7 and Network Interconnect is needed to passing out-of-band signaling messages and supporting high-speed data connectivity - both vital to the success of inter-switch ISDN.

The last step of our analysis is to identify the future changes that have to occur to move ISDN from a "vendor-push technology" to a "market-driven success". For any technology to successfully make this transition the vendors have to answer the implicit (or explicit) question from the marketplace: "Hey, what's in it for me to buy this...?" Just as the Personal Computer industry found their lifeblood in application software, ISDN must be driven by the same kinds of creative minds that put technology to use in the layperson's world. However, to accomplish this we need to have the same capability that PC applications depend upon for successful software development: a standard interface.

Personal Computers have had a limited set of operating systems and backplane interfaces over the years. Arguably, the most popular combination has been the PC/XT/AT hardware and DOS software. Because these were published interfaces many different vendors could build hardware peripherals or write software packages to be sold with these computers. Some of the benefits to the end user included feature competition, multi-vendor interoperability, increased cost/benefit ratios and more. There already exists standard hardware interfaces defined for ISDN. What ISDN needs more are some standard interfaces to the world of software.

The three architectures that this software would support are: 1), PBX-to-Host Computer; 2), Desktop/PC-to-Central Office; and, 3), Host Computer-to-Central Office. Because the first architecture is fairly well understood by a large population of PBX and Host Computer vendors and the third architecture does not appear to have a large group of devotees, we will focus the remainder of the discussion on the second architecture. This is where similarities between the spreadsheet software, which was needed to justify my Personal Computer, can be seen with the need for software to justify my ISDN decisions.

Software for ISDN today has to be written to an applications programing interface (API) for the Personal Computer Terminal Adapter (PCTA). Today this API is vendor-specific, which has some advantages but carries for the user some potentially frustrating consequences. The main advantages for a vendor-specific interface is the constant "cost/feature-wars" as each vendor shows why you should purchase their PCTA. The problem is that if you purchase software that is written for just one PCTA's API you are left stranded if the vendor goes out-of-business, can't afford to invest in additional applications, or doesn't think your particular application warrants the investment. To avoid these unfavorable situations, we need a standard way that an application can talk to any PCTA - we need a standard API for our ISDN applications.

The group that is advancing this process is the Applications Software Interface group which is sponsored by North American ISDN Users Forum (NIU). Cheng Chen of Teleos Corporation is the Chairman for this group which has just this past October received approval of the API they have been working on. The "vendor's agreement" (they aren't chartered as a standards group) for the API supports a small set of subroutine calls for DOS-based architectures. Unix and OS/2 work is due to be completed by the end of 1992 which will further increase the benefit of this API. There have even been meetings to see how the work being done by the NIU group might be "harmonized" with European versions of this capability. Yet, there is still work that vendors and end users need to do here in the North American marketplace - support, fully, the work done by the ASI committee.

One of the biggest threats to the "standardized" API is lack of support from PCTA vendors. The fear is that they will provide SOME support, but that they will continue to promote their proprietary solution. It would only make good marketing sense to "support" this API but encourage vendors to build to the "richer vendor-specific API for more capabilities...". This "damning with faint praise..." could leave the market place with the same liabilities as not having one at all. Therefore for ISDN applications successes to extend industry-wide we need both vendor- AND USER support for this interface.

Support in free enterprise means that

you purchase the products that will help you (both in the long- and short-term). This also means that you don't purchase products that will hinder the growth of this capability. If your vendor of PCTAs doesn't support (read: implement!) the ASI API tell them that you think that it's important for your software investment and business applications. If they do support it (i.e.: Teleos and Link Technologies), tell your software vendor that you'd like to use their products and ISDN service and that you're buying software from vendors that support the ASI API. Unless we implement these methods of "support" for the API, we may see a very stagnant software development effort for ISDN. And without the software to pull-through sales, ISDN could take much longer to serve end-users with the applications that only a truly integrated interface can provide.

2500 Sets (aka POTS sets): Single-line, analog telephones

ANI: See Automatic Number Identification

Automatic Number Identification (aka: ANI, Calling Line Identification, CLID, Incoming Calling Line Identification, ICLID): Delivery of the CALLING telephone number to the subscriber at the CALLED end. Differs from Station Identification (or, Customer Station Identification) because ANI is the number that is BILLED and may not indicate the extension number of the telephone.

Basic Interface (aka: Basic Rate Interface, BRI, Basic Rate Access, BRA): Two (2) Full-Duplex, Circuit-Switched "Bearer" Channels at 64Kbs each, plus one "Delta" Channel at 16Kbs for Q.931 Signaling Messages and X.25 User Data Packets.

Basic Rate Access: See Basic Interface

Basic Rate Interface: See Basic Interface

Bearer Channel: A 64Kbs Full-Duplex Circuit-Switched Channel which can be used for voice, circuit-switched data, or "nailed-up" to a packet device to carry higher-speed (56- or 64Kbs) user data packets

BRA: See Basic Interface

BRI: See Basic Interface

CLID: See Automatic Number Identification

Calling Line Identification: See Automatic Number Identification

CPE: See Customer Provided Equipment

CSI: See Station Identification

Customer Provided Equipment (aka: CPE): Customer-owned telecommunications equipment (i.e.: telephone sets, fax machines, PBXs, etc.)

Customer Station Identification: See Station Identification

D-Channel: See Delta Channel

Data Channel: See Delta Channel

Delta Channel (aka: D-Channel, Data Channel): The signaling channel used for setting up and controlling Bearer Channels. On the Basic Interface it is defined as 16Kbs and can carry both the Q.931 Signaling Messages AND X.25 user data packets. On the Primary Rate Interface it is defined as 64Kbs and carries Q.931 signaling messages ONLY.

ICLID: See Automatic Number Identification

IEC: See Interexchange Carrier

Incoming Calling Line Identification: See Automatic Number Identification

Interexchange Carrier (aka: IEC, IXC): Companies allowed to carry traffic across LATA boundaries (i.e.: AT&T, MCI, US Sprint).

IXC: See Interexchange Carrier

LATA: See Local Access Transport Area

LEC: See Local Exchange Company

Local Access Transport Area (aka: LATA): A geographical area which roughly conforms to a local calling area. LECs are allowed to carry traffic within LATA boundaries, but are required to send inter-LATA traffic to an Interexchange Carrier.

Local Exchange Companies (aka: LECs): The telephone company for a particular area.

NFAS: See Non Facility-Associated Signaling

Non Facility-Associated Signaling: In ISDN, a method of signaling which allows an active D-channel in one Primary Rate Interface to set-up and control calls in a separate Primary Rate Interface.

PABX: See Private Branch Exchange

PBX: See Private Branch Exchange

Plain Old Telephone Service (aka: POTS): Traditional analog telephone service using rotary-dial or Touch-Tone phones.

POTS: See Plain Old Telephone Service

PRA: See Primary Rate Interface

PRI: See Primary Rate Interface

Primary Rate Interface: Twenty-three (23) Full-Duplex, Circuit-Switched "Bearer" Channels at 64Kbs, plus one "Delta" Channel at 64Kbs for Q.931 Signaling Messages (alternative configuration with Non Facility-Associated Signaling is twenty-four "Bearer" Channels).

SID: See Station Identification

Station Identification (aka: SID, Customer Station Identification, CSI): A customer-provided outpulsing of the calling station's identification (usually the extension number). Differs from the delivery of the BILLING number (Automatic Number Identification) in that not every communications system sends SID and not every network delivers SID.

An Advanced Satellite Communication System for ISDN Subscriber and Trunk Applications

1. ABSTRACT

This paper describes an advanced satellite communication system for ISDN subscriber and trunk applications. NTT has developed a new satellite communication system, DYANET-II (DYnamic channel Assigning and routing satellite aided digital NETwork-II) integrated into a terrestrial ISDN, by extending the system concept of DYANET. To apply satellite communications to the ISDN subscriber portion, in addition to the trunk portion, new network control technologies have been developed to achieve efficient satellite channel utilization and a single hop connection in DYANET-II. Moreover, compact earth station equipment has been developed for customer premise use.

2. INTRODUCTION

Satellite communications have unique features that terrestrial systems do not have. These include multiple access capability, wide coverage of service areas, and rapid and flexible network re-arrangement. From the viewpoint of traffic concentration, satellite communications can gather light traffic scattered over a wide area and carry it through common satellite channels.

NTT has recently developed a novel satellite communication system called "DYnamic channel Assigning and routing satellite aided digital NETwork (DYANET)" which takes advantage of the above-mentioned features of satellite communications. DYANET is used in combination with terrestrial networks, and it carries overflowed traffic among transit switches through common satellite channels. The main feature of DYANET is that its function is equivalent to a single transit switch. DYANET has been in commercial use since October 1988(1) (2) (3).

NTT initiated ISDN services in April 1988(4). In the evolutional phase of ISDN services, the service area is limited because a long time is needed to establish the infrastructure of ISDN all over Japan. Therefore, A communication system is strongly required that can economically accommodate ISDN subscribers at an area far from the service access point for fast and nationwide expansion of ISDN services. Satellite communication is one of the most promising ways of doing this, because ISDN subscribers can be accommodated by installing an earth station on the customer premises. Subscriber application using satellite communications will also be useful for temporary or emergency use.

To accomplish the above-mentioned purpose, an advanced satellite communication system, DYANET-II has been newly developed for ISDN subscriber and trunk applications, by extending the system concept of DYANET. This paper describes the system concept and network configuration of DYANET-II, which are followed by an advanced network control system and a radio communication system for DYANET-II.

3. SYSTEM CONCEPT OF DYANET-II

3.1 FEATURES OF SATELLITE COMMUNICATIONS

Figure 1 shows the network structure using satellite and terrestrial communication systems from the viewpoint of traffic concentration. A communication network generally consists of many transmission sections that are classified to categories: a trunk portion and a subscriber portion. For a trunk portion in terrestrial systems, regional traffic is concentrated by exchangers and this concentrated traffic is economically carried by high-capacity transmission systems. The terrestrial communication systems are more suitable than satellite, when traffic is heavy and sufficiently concentrated within adjacent areas. On the other hand, by taking advantage of satellite communications' multiple access capability and wide service area coverage, variable and widely dispersed traffic can be easily concentrated and many sections can use common satellite circuits on a time-sharing basis. This means that satellite communication systems are more suitable than terrestrial systems for carrying light and variable traffic dispersed over a wide area.

Features of terrestrial and satellite communication systems are shown in Fig.2. This figure indicates that the most economical ISDN can be created by combining satellite systems with terrestrial systems.

3.2 APPLICATION FOR TRUNK PORTION

Let us suppose that a transit switch selects the first routing circuits and it selects the second routing circuits only when all of the first routing circuits are occupied. By applying this routing principle, trunk traffic is classified to two groups: one is heavy and constant traffic and the other is light and variable traffic.

In DYANET, the former traffic is carried by high-capacity terrestrial transmission systems such as optical fiber transmission systems, and the latter traffic is carried by demand-assignment satellite communication systems, where satellite channels are set up on a call-by-call basis between an originating transit switch and a terminating transit

switch nearest to the called party. "Farthest end routing" control, is adopted to select a terminating transit switch and an earth station connected to it.

In this way, a terrestrial transmission system is used very efficiently. The satellite channels are also efficiently used compared with pre-assigned satellite channels, since the satellite channels are used in common by many transit sections on a time sharing basis. The integration of satellite communication networks with terrestrial networks makes it possible to reduce total transit network cost by reducing the required number of trunk circuits to meet the specified blocking rate (0.01, for example).

3.3 APPLICATIONS FOR SUBSCRIBER PORTION

In the evolutional stage of ISDN services, ISDN subscriber lines are not available or not cost effective, especially in rural areas where subscriber traffic is scattered over a wide area. This situation is more real for primary rate ISDN services since a lot of time and cost are needed to establish an optical subscriber network infrastructure.

On the other hand, considering traffic characteristics on the subscriber portion, the calling rate is around 0.1 erl. per one B-channel even for business use. This is significantly low traffic compared with trunk traffic. In addition to that, this traffic is time-varying according to the usage of customers. These traffic characteristics are basically suitable to satellite communications application. Since many ISDN subscribers can share a common satellite on a demand basis, satellite communications can be useful in supplementing a terrestrial ISDN. Such a satellite communication system can accommodate five-to-ten times as many ISDN subscribers as a pre-assignment satellite communication system.

3.4 REQUIREMENTS FOR APPLICATION OF SATELLITE COMMUNICATIONS TO ISDN

Figure 3 illustrates the network configuration of ISDN in Japan, where both basic rate and primary rate user-network interfaces (UNI) are offered. Layer 1 user-network interface (UNI) for both basic and primary rates meets CCITT recommendations I.430 and I.431. The 2B+D configuration for basic rate UNI provides customers with two 64kb/s information channels and a separate 16kb/s signaling channel. On the other hand, the primary rate interface provides customers with 24x64kb/s channels, for a total capacity of 1.5Mb/s. In addition, as shown in Fig. 3, a conventional public switched telephone network (PSTN) is incorporated in ISDN, except in the subscriber portion.

There are essential requirements from the viewpoint of network services, especially for subscriber applications, when considering the satellite communication applications to a public ISDN. First, it is indispensable to provide the customers using satellite with the same ISDN services for those using terrestrial transmission, in terms of the numbering, signaling, and charging system, as well as user-network interface. This means that customers will not face subscriber number changing when they are served by a terrestrial transmission media in the future. It also means that the communication tariff does not depend on the transmission media, satellite or terrestrial. This basic system concept makes it possible to avoid a drastic modification of a terrestrial ISDN for applying satellite communications to ISDN. Moreover, it requires the utilization of satellite channels more efficiently because they are limited resources.

Taking the above-mentioned requirements into account, an advanced satellite communication system called "DYANET-II" has been developed, for both the trunk and subscriber portion, by extending the system concept of DYANET.

4 NETWORK CONFIGURATION OF DYANET-II

4.1 SYSTEM CONFIGURATION

In a terrestrial ISDN, each subscriber is connected to a designated local switch, to which an area code is assigned according to the numbering plan. To apply the same numbering, signaling, and charging system to satellite subscribers as terrestrial subscribers, an ISDN satellite subscriber is accommodated by the local switch covering the service area in the same manner as a terrestrial ISDN subscriber.

The network configuration of DYANET-II is shown in Fig. 4. DYANET-II consists of a communication satellite using Ku band, a control earth station (CES), base earth stations (BESs), user earth stations (UESs), a satellite channel control unit (SCU), and a satellite communication transit exchange unit (SXU), with local switches (LSs) and transit switches (TSs).

A UES is installed on customer premises and it offers basic and primary rate user-network interface for ISDN services. A UES is virtually connected to an LS according to the numbering plan. A BES has two sorts of terrestrial interfaces: one is a subscriber interface and the other is a trunk interface. The subscriber interface of a BES is connected to the subscriber circuits of an LS. Trunk circuits of an LS and TS can be connected to the trunk interface of a BES to carry overflowed trunk traffic as in DYANET.

4.2 FUNCTION OF DYANET-II

SXU is connected to LSs and TSs via a common channel signaling (CCS) network. SXU and LSs accommodating satellite ISDN subscribers are connected to SCU via a dedicated data communication network. An LS terminates call control signals on the subscriber portion (between an ISDN subscriber and an LS) and transmits satellite channel control signals to SCU. Regarding call control signals on the trunk portion (between SXU and an LS/TS), SXU terminates them and transmits satellite channel control signals to SCU. According to satellite channel control signals from LSs and SXU, SCU sets up and releases satellite channels, by sending satellite channel assignment signals to UESs/BESs through satellite circuits. It is noted that each LS has the similar functions to SXU in DYANET-II. Therefore, a satellite channel control software has been newly developed and implemented in each LS.

SXU carries out switching control of the trunk circuits and the LSs carry out switching control of the subscriber circuits in DYANET-II. When a call is routed to SXU, it chooses the terminating BES and a terminating LS/TS closest to the called party by "farthest end routing", to ensure a single hop connection on the trunk portion. If a called party is an ISDN satellite subscriber, a terminating LS sends SCU satellite channel control signals to change the

connection of the satellite channels. In this way, a single hop connection is ensured for any connection, such as a UES-UES or UES-BES connection.

Figure 5 shows an equivalent network model of DYANET-II. DYANET-II applies a demand-assignment TDMA (Time Division Multiple Access) scheme with carrier (transponder) hopping capability. As satellite channels are set up on a call-by-call basis by assigning a time slot on a TDMA frame and a carrier frequency to a BES/UES, the satellite system of DYANET-II comprising UESs and BESs is essentially equivalent to a dispersed switch circuit combining a subscriber portion with a trunk portion. An LS has "control functions" for satellite channels on a subscriber portion and SXU has "control functions" for satellite channels on a trunk portion. Therefore, the function of DYANET-II is essentially equivalent to a dispersed switch circuit controlled by an SXU and LSs.

4.3 ACCESS CHANNEL SPLITTING CONTROL

In a terrestrial subscriber line, all channels exist at every moment. However, such a channel on the subscriber portion is actually used only when a call occurs. Therefore, all channels do not necessarily need to exist at every moment. For efficient utilization of satellite channels, a satellite channel in actual use should be set up on a demand-assignment basis. In addition, to meet CCITT recommendation G.114 on end-to-end delay for telephone services, it is indispensable to ensure a single hop connection between any earth stations including subscriber earth stations. This implies that each satellite channel on the subscriber portion should be handled separately since it can have a different destination. For this purpose, "access channel splitting" control has been newly introduced.

The satellite access channel of DYANET-II is handled as follows:

(a) While a subscriber interface layer-1 is activated, a satellite channel for D-channel is set up between the terminal and the local switch.
(b) While a call is progress, satellite channels for the B/H-channel are set up depending on the information transfer rate of that call.
(c) Satellite connection of the B/H-channel can be changed according to the destination of the call to ensure a single hop connection.

4.4 ECHO CONTROL

The terrestrial interface of the trunk portion at a BES is illustrated in Fig.6. Echo cancellers are implemented between a BES and a TS/LS at the trunk circuit for audio/speech call. SXU and the TS/LS select the trunk circuit with/without an echo canceller according to the call type (non-restricted bearer or audio/speech call) on a call-by-call basis.

For echo control in a subscriber portion, echo cancellers are implemented in both a UES and a BES. Switching of those are controlled by an ISM according to the call type on a call-by-call basis. Figure 7 shows an example of a connection for satellite subscribers. For a UES-UES connection, echo cancellers on both UESs are enabled for audio/speech call. They are disabled for non-restricted bearer call.

4.5 SUBSCRIBER CONTROL SIGNAL TRANSMISSION

B/H- and D-channel are managed by SCU and they are set up on a call-by-call basis. On the other hand, a data channel for satellite channel control is established between SCU and each BES/UES through CES on a pre-assignment basis. In a terrestrial subscriber transmission, subscriber control signals for Layer-1 activation/inactivation control at T reference point and operation administration and maintenance, are included along with B/H- and D-channels. In DYANET-II, satellite channel control circuits are also used to transmit/receive these subscriber control signals. To utilize satellite channel control circuits efficiently, a novel technique has been developed; that is, subscriber control signals are transmitted to SCU as packet data, only when a transition of subscriber control signals occurs. SCU transfers the received data from a UES/BES to the designated BES/UES. Therefore, SCU works as a packet switch for subscriber control signal transmission.

5. NETWORK CONTROL SYSTEM FOR DYANET-II

5.1 FARTHEST END ROUTING CONTROL

Demand assignment satellite channels are established dynamically between earth stations. To avoid a multi-hop connection of a satellite channel and efficiently use satellite channels, DYANET-II adopts "farthest end routing" control, which selects a direct route to the BES farthest from the originating TS/LS; that is to the BES nearest to the terminating terrestrial subscriber or the BES, to which the terminating UES is connected. SXU determines the farthest end BES according to the destination number.

The concept of "farthest end routing" in DYANET-II is shown in Fig. 8. Suppose that a UES connected to LS-1 calls to a terrestrial terminal connected to another LS-2. SXU translates the destination number and selects the terminating BES and LS or TS nearest the terrestrial terminal (i.e. BES-4 and LS-2) from among the possible terminating BESs at TSs/LSs. It should be noted that "farthest end routing" is effective in avoiding multi-hop a connection on the trunk portion only.

5.2 CHANGE CONNECTION CONTROL

In a public switched network, an end-to-end connection is established on a link-by-link basis by each switching node. Therefore, if a satellite channel is set up on the subscriber portion (between a UES and a BES) and the called party is a satellite subscriber, change connection is indispensable in establishing a single hop connection between two UESs or a UES and another BES. To ensure a single hop connection for a UES-UES or a UES-BES connection, "change connection control" has been newly developed for DYANET-II.

Figure 9 shows an example of "change connection control" to establish a single hop connection between two UESs.

(a) Phase 1: When a satellite subscriber generates a call, a satellite channel is set up between a UES (calling subscriber) and a BES connected to the originating LS. Then, the LS sends call control signals to SXU via CCS.
(b) Phase 2: SXU carries out "farthest end routing" control and establishes the connection between the originating LS and the terminating LS via

CCS. In addition, SXU sends satellite channel control signals to SCU to change the connection. As a result, a satellite channel is established between the UES (calling subscriber) and the BES connected to the terminating LS.

(c) Phase 3: The terminating LS sends satellite channel control signals to SCU to change the connection again. Finally, the connection between the originating UES and the terminating UES (called subscriber) is established.

5.3 D-CHANNEL DEMAND ASSIGNMENT CONTROL

DYANET-II supports the same layer-1 activation/inactivation sequence for satellite subscribers. Figure 10 shows the layer-1 activation procedure for a satellite subscriber. INFO signals indicate layer-1 statuses. Layer-1 control signals, INFO 1' - INFO 4', correspond to the INFO signal defined by CCITT recommendation I.430. SCU checks all layer-1 control signals received from UESs and BESs. When SCU detects layer-1 activation such as INFO 1', it establishes a satellite channel for D-channel. Similarly, SCU releases the satellite channel by detecting layer-1 deactivation.

5.4 CALL CONTROL PROCEDURE

Figure 11 shows an example of a call control procedure when both originating and terminating subscribers are accommodated by satellite. The procedure consists of three phases as described bellow:

(A) Phase 1

(a) When the user terminal initiates a call with layer-1 activation, a satellite channel for D-channel is established. After establishment of the D-channel and layer-1 activation, the originating terminal sends SETUP to the LS.

(b) When the LS receives the SETUP message , it transmits CSR (channel setup request) to SCU. SCU sets up a satellite channel between the originating UES and the BES connected to the originating LS.

(c) When SCU confirms the establishment of a satellite channel between the UES and the BES, SCU sends a CSA (Channel Setup Ack) to the originating LS.

(d) After receiving the CSA from SCU, the LS sends CALL PROC to the originating terminal. It sends an IAM (Initial Address Message) to SXU, as well.

(B) Phase 2

(a) When SXU receives the IAM from the originating LS, SXU determines the terminating BES according to the farthest end routing and sends a CCR (Change Connection Request) to SCU.

(b)When SCU receives the CCR from SXU, SCU searches the first connection between the UES and the BES connected to the originating LS, releases it and establishes a satellite channel between the UES and the BES determined by "farthest end routing". As a result, change connection is carried out.

(c) When SCU confirms change connection, SCU sends a CCA to SXU.

(d) SXU sends an IAM to the terminating LS.

(C) Phase 3

(a) When the terminating LS receives the IAM, it distinguishes whether the called party is a satellite subscriber. If the called party is a satellite subscriber, the LS sends a CCR to SCU. If the layer-1 is not activated, a satellite channel for D-channel is set up with layer-1 activation.

(b) SCU carries out change connection again and establishes a satellite channel between the originating UES and the terminating UES. After that, SCU sends a CCA to the terminating LS.

(c) The terminating LS sends SETUP to the called terminal. Finally, a communication path is established.

6. RADIO SYSTEM FOR DYANET-II

DYANET-II has been designed to offer communication channels at rate of B-channel (64kb/s) to H1-channel (1536kb/s) for the application to ISDN. The TDMA approach is the most appropriate to handle multi-speed traffic and adopt access channel splitting control(5). Though the TDMA scheme requires complicated digital hardware for burst synchronization control, it needs only one modem for various bit rate transmission if the bit rate is lower than the modem transmission rate. In addition, recent advances in LSI implementation reduce the size and cost of the TDMA equipment. Considering the above, DYANET-II adopts the TDMA scheme instead of other multiple access schemes such as FDMA.

The bit rate, modem scheme and FEC for the TDMA system have been optimized, taking into account antenna size and HPA output power for installation of an earth station on customer premises.

The computer and hardware simulation results show that the best compromise is two carrier transmission, each of which carries 17.6Mb/s signals, per 27MHz band width transponder with transmitting power control. To achieve high spectrum utilization efficiently, offset QPSK has been employed. Carrier (transponder) hopping has been adopted to increase the transmission capacity of the TDMA system and to ensure connectivity among earth stations.

In DYANET-II, there are three kinds of earth stations, as described previously. Table 1 shows the major radio system parameters.

7. CONCLUSION

An advanced satellite communication system for ISDN subscriber and trunk applications, which is integrated into a terrestrial ISDN, has been achieved using new developments in novel network control technologies.

ACKNOWLEDGMENT

The authors would like to thank Dr. Tetsuaki Egawa of NTT Communication Switching Laboratories and Dr. Yoshiteru Morihiro of NTT Network Systems Development Center for their guidance and useful suggestions. The authors also thank the participants in the development of DYANET-II for their great contributions.

1. ABSTRACT

This paper proposes an advanced network control system for satellite communication systems that are integrated into a terrestrial public telecommunication network. The key technology is a centralized network control system for ensuring single-hop connection and achieving efficient satellite channel use. The network control system consists of multiple satellite channel control units (SCUs) and a satellite communication transit exchange unit (SXU). This control system controls satellite channels according to requests from terrestrial switching nodes. Functional requirements for the proposed network control system to expand the application of satellite communication systems to ISDN subscribers and local switching systems are discussed and a new network control technology is proposed in this paper.

2. INTRODUCTION

Satellite communication systems feature wide area coverage, easy link establishment, and so on. Because of such features, satellite communications have been introduced for communication links to remote islands, and for temporary or emergency use.

Since the launching of Japan's communication satellite CS-2 in 1983, satellite communication systems have been introduced for the above purposes in Japan. NTT developed a new domestic satellite communication system called "DYnamic channel Assigning and routing satellite aided digital NETworks (DYANET)" and introduced this system using the CS-3s launched in 1988. The DYANET has been applied mainly for transit links in the public switched telecommunications networks (PSTN) (1) (2) (3).

This paper describes the functional requirements and key technologies of the proposed network control system for expanding the application of satellite communication systems to ISDN subscribers and local switching systems. Ordinary satellite communication systems set up fixed satellite links between communication nodes. Such systems cannot concentrate traffic, so the satellite channel utilization is very low and the number of applicable satellite links is small. Also, satellite links have a propagation delay of about 250 ms in single-hop connection, so we need to avoid multiple-hop connection in one call as much as possible. However, in ordinary satellite communication systems, multiple-hop connection cannot always be avoided.

We have resolved these problems by adding new functions to DYANET. First, we describe the fundamental concept of DYANET, and the functional requirements for expanding applications. Then, we study link control technology for multiple satellite communication systems, furthest-end routing technology, connection control technology for subscriber calls with single-hop connection, and connection control technology for local switching systems.

3. FUNDAMENTAL CONCEPT OF DYANET AND FUNCTIONAL REQUIREMENTS FOR EXPANDING APPLICATION

3.1 FUNDAMENTAL CONCEPT OF DYANET

In the DYANET system, overflow traffic from many terrestrial transit sections will be carried by the satellite communication system by using terrestrial channels as the first routing channel group and satellite channels as the second routing channel group. In this case, satellite channels are used as one common channel group for transit traffic fluctuations in all transit sections. By using the DYANET system together with the terrestrial network, we can make public telecommunication networks more flexible, cost effective and reliable.

The system configuration of DYANET and its equivalent model are shown in Figure 1. DYANET applies a demand assignment TDMA (Time Division Multiple Access) scheme with transponder hopping capability. In this scheme, a satellite channel is established by having an ES transmit a burst signal over each channel in an assigned time slot. This function can be regarded as a time division switching network. DYANET is equivalent to a large dispersed transit switch consisting of many earth stations (ESs) and satellite control systems (CSs).

In applying such an equivalent transit switching system with a call connection function to existing services (B channel audio/speech/unrestricted digital and H channel) and the existing signaling system (CCS No.7 ISUP), we integrated DYANET into PSTN without adding any new functions to the existing switching systems. Satellite control systems have two main functions: one is assigning and setting up satellite channels between ESs on a call-by-call basis, and the other is selecting a terminating ES and TS, establishing satellite channels between transit switches (TSs), and relaying call control signals to a terminating TS. We implement the first function as a satellite channel control unit (SCU), and the second as a satellite communication transit exchange unit (SXU).

Fig. 1 DYANET SYSTEM ARCHITECTURE

3.2 FUNCTIONAL REQUIREMENTS FOR EXPANDING APPLICATION

As the first step in expanding the DYANET to the PSTN, we have applied the DYANET to 62 Zone Centers (ZCs) in the nation-wide ISDN transit network. There are several requirements for applying satellite communication system to the existing network.

(i) Applying satellite channels to final trunk circuits for local switching nodes (GC: group center, or UC: unit center) on remote islands (switching nodes with final trunk only)
(ii) Applying satellite channels to second route transit trunk circuits between UC and GC for high reliability (switching nodes with double routes)
(iii) Applying satellite channels between a transportable earth station and a transit node for temporary or emergency use (transportable switching nodes)
(iv) Applying satellite channels to ISDN subscriber access portions for rural areas.

Satisfying these requirements, it is necessary to consider the features of the satellite communication system and the PSTN.

(1) Integration of multiple satellite communication systems
Satellite communication systems vary in certain categories (bit rate and transmission frequency etc.) according to their purposes, which makes interconnection or resource sharing difficult. In satellite communication systems, single-hop connection and high satellite channel utilization rate are strongly desired. Thus a centralized control scheme is needed to integrate multiple satellite communication systems into the PSTN.

(2) Integration of subscriber access portion and trunk portion
When we apply a satellite channel to the subscriber access portion, double-hop connection may occur in connections between satellite subscribers or between a satellite subscriber and a satellite trunk. To avoid such double-hop connections, technology that provides single-hop connection between satellite subscribers or between a satellite subscriber and a satellite trunk is essential. (Figure 2)

(3) Call connection control technology for supplementary service calls for application to local switching nodes
For trunk applications between ZCs, general transit calls are the only type of calls handled. For trunk applications in local switching nodes such as UC or GC, however, call connection control technology for supplementary service calls, such as 1XY and 0AB0, is needed. Furthermore, existing analogue signaling systems (such as a channel associated signaling system) are additionally implemented by a satellite communication network control system.

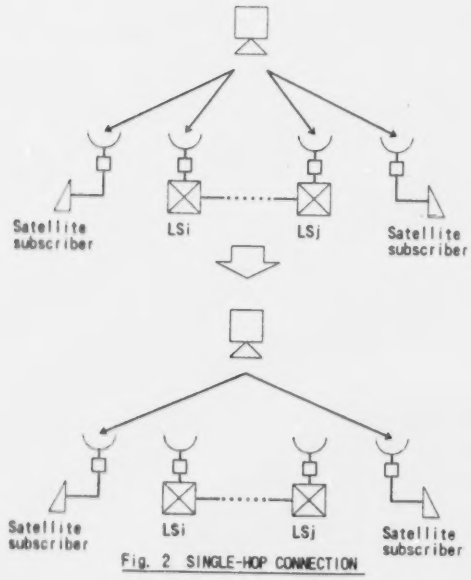

Fig. 2 SINGLE-HOP CONNECTION

4. CALL CONNECTION CONTROL IN DYANET

4.1 SATELLITE NETWORK ARCHITECTURE

Satellite communication systems differ in transmission frequency, bit rate, type of communication satellite, and so on. Direct accommodation of transit trunks of B channels and H channels and subscriber lines is considered one application. In Japan's present domestic communication satellite, interconnection of different types of earth stations is not possible, but improvements in the satellite itself, for example

adding an on-board cross-strapping function, will allow such interconnection in the near future. When such improvements are made in the satellite, we should add new functions not to the existing PSTN, but to the satellite network control system.

Also, the desirability of expanding the satellite network control system independently of advances in satellite communication technology, switching technology, and network technology should be considered in discussions about function assignment between the SXU and the SCU. As there are multiple types of satellites and earth stations in various phases of development, these functional additions should be assigned to the SCU. And the SXU should expand the utilization of the interface with existing switching systems and integrated routing among multiple satellite communication networks. An architecture for an advanced network control system for an ISDN satellite communication system is shown in Figure 3. As shown in Figure 3, there are several kinds of satellite speech path network corresponding to multiple types of ESs and SCUs, which are controled by the SXU. Such control is achieved by the following functions in the SXU.

(i) Deciding a satellite speech path network which is possible to connect between incoming and outgoing calls
(ii) Managing satellite channel resources conditions of every type of satellite speech path network
(iii) Maintaining a list of relationships among types of satellite speech path network in accordance with future integration of these networks (Figure 4)

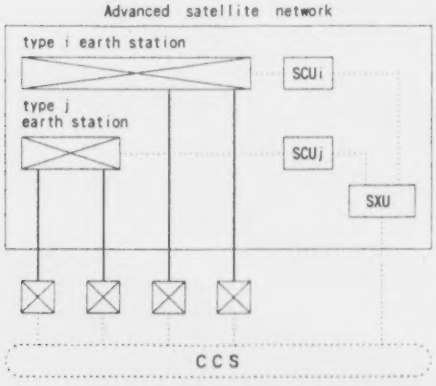

Fig. 3 ADVANCED SATELLITE NETWORK ARCHITECTURE

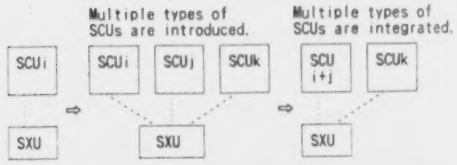

Fig. 4 FUTURE FORM OF VARIOUS TYPES OF EARTH STATIONS

4.2 FARTHEST-END ROUTING SCHEME IN AN ADVANCED NETWORK CONTROL SYSTEM FOR ISDN

There are different types of ESs in an integrated satellite network that are not interconnectable, so the farthest-end ES must be selected out of ESs of the same type.

In existing networks, calls are connected link-by-link in a transit network, and the originating switching node selects a terminating switching node and a trunk circuit. Therefore, a satellite speech path network is decided when a ES is selected out of ESs of different types by an originating node. In this case, the SXU transits the call in this satellite speech path network which was decided by the originating node. On the other hand, if a function to re-select the type of ES were provided to the originating node, it could be possible to select the satellite network to connect with perfect farthest-end routing. The concept of farthest-end routing is represented in Figure 5. A farthest-end route will be decided from the most digits in the list of address numbers which are matching to originating and outgoing ES types. The following alternative routing methods are available.

(I) Individual translators:
By installing translator tables in each type of ES, the originating node can search these tables of ESs which it can connect and decide the channel with the most digits in the list of address numbers.

(II) Common translator:
Regardless of the originating node, by searching all farthest-end points connected to the terminating subscriber, the SXU can select an appropriate farthest terminating route by matching the type of the originating and terminating ESs.

Diagrams of these implementation methods are shown in Figure 6.

Method (I) requires the translator table which is large in proportion to the number of ES types. Method (II) requires twice the memory required by general switching systems, but this translator system can be implemented without regard to the number of ES types. In other words, if that there are more than three ES types, method (II) has advantages in memory size.

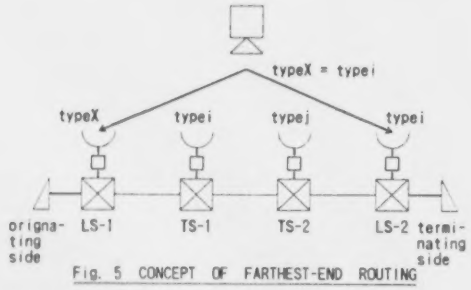

Fig. 5 CONCEPT OF FARTHEST-END ROUTING

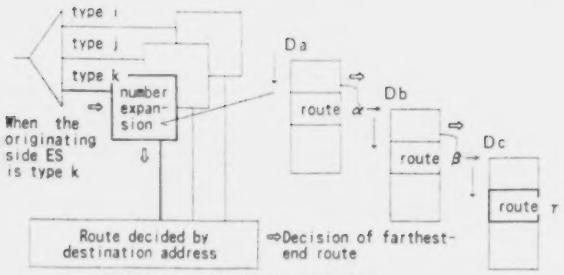
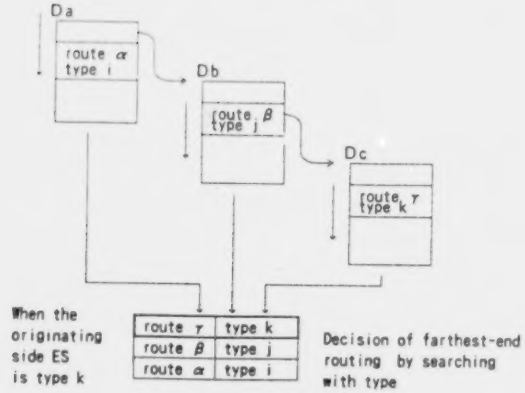


METHOD (I) INDIVIDUAL TRANSLATOR



METHOD (II) COMMON TRANSLATOR

Fig. 6 COMPOSITION OF TRANSLATOR

4.3 INTEGRATION OF LOCAL AND TRANSIT CALL CONNECTION CONTROL

To establish satellite channels as subscriber access portion and trunk portion, the following functions are needed.

A) Unifying management of satellite channel resources

B) Unifying requests to set and release a satellite channel to ESs

C) Relaying the information which indicates the satellite channel number connected between a subscriber's ES (UES) and a transit ES(TES)

D) Requesting to change a set satellite channel to another one

E) Identifying from address number, whether a terminating subscriber is a satellite subscriber or terrestrial subscriber

Functions A) and B) are implemented by the SCU; that is, the request to set and release satellite channels for subscriber access portion is sent from local switching system to the SCU. In transit switching systems, functions A) and B) are implemented by sending a request from the SXU to the SCU.

Functions C) and D) are implemented by the SXU and LS; that is, the additional information can be easily sent by CCS No.7 ISUP.

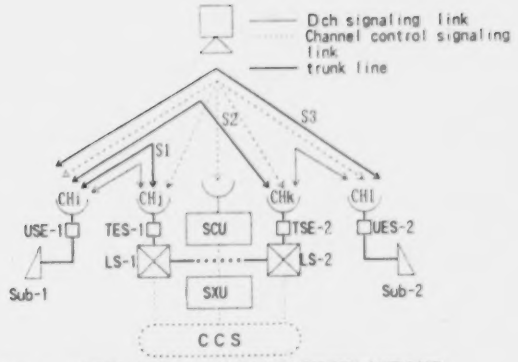


Fig. 7 DIAGRAM OF MUTUAL CONNECTION BETWEEN SATELLITE SUBSCRIBERS

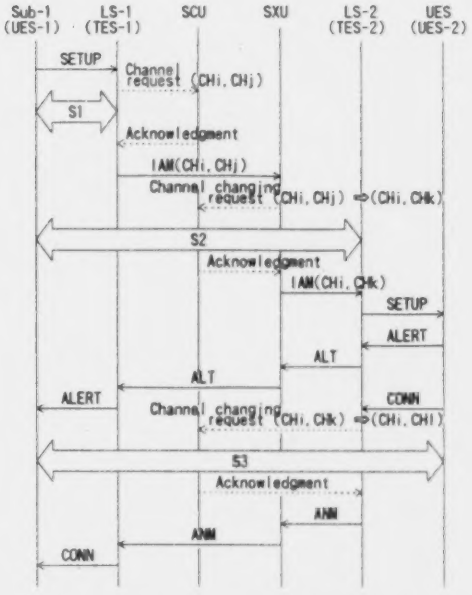

Fig. 8 SIGNALING PROCEDURE OF MUTUAL CONNECTION BETWEEN SATELLITE SUBSCRIBERS

And function E) is implemented by adding new functions only to the SXU; that is, the SXU can identify whether the terminating subscriber is a satellite subscriber or not by checking a list of satellite subscriber's number and type of UES.

A diagram and signaling procedure of mutual connection between satellite subscribers are shown in Figures 7 and 8.

i) The SCU sets the satellite channel between UES-1 and TES-1 since the call is originated from a satellite subscriber.

ii) LS-1 sends call control information to the SXU via CCS No.7 when the terminating subscriber is accommodated to another LS. The channel information used to set the channel between UES-1 and TES-1 is sent as an optional parameter in CCS No.7.

iii) The SXU identifies whether the terminating subscriber is a satellite subscriber or terrestrial subscriber, and classfies the terminating subscriber (satellite/terrestrial) and type of terminating ES. And the SXU selects the channel between LS-2 and TES-2 by farthest-end, which is described in section 3.2. And then the SXU sends the SCU a request to change the satellite channel by sending the channel information of UES-1 and the selected TES-2, and the SXU changes the satellite channel connection from S1 to S2. The channel information which represents the satellite channel between UES-1 and TES-2 is also sent to LS-2 by an optional parameter in CCS No.7, the same as ii).

iv) LS-2 identfies the originating subscriber is a satellite subscriber or not by an optional parameter. When the originating subscriber is a satellite subscriber , LS-2 sends a request signal to set a satellite channel between UES-1 and UES-2, and changes the satellite channel connection from S2 to S3.

4.4 AVOIDING OF DOUBLE-HOP CONNECTION

Although double-hop connection should be avoided as much as possible, there are some cases in which cannot be avoided if connection is to be assured between local switching nodes with final trunk only or between satellite subscribers in the present satellite network which has multiple types of ESs. Thus, the SXU judges the necessity of double-hop connection according to the form of connection, because the SXU decides the routing of a satellite channel. This control is implemented by analyzing the information, such as satellite routing indicator, or subscriber classification (which represents whether the originating subscriber is a satellite subscriber or terrestrial subscriber) and the originating office classification (which represents whether the originating ES is a general office or a local switching office with final trunk only). This control scheme is shown in Figure 9.

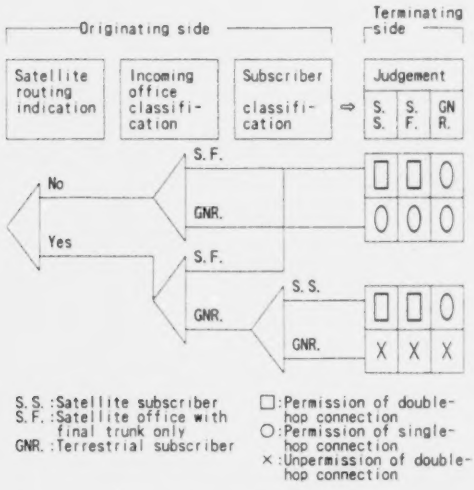

Fig. 9 JUDGEMENT OF PERMISSION OF DOUBLE-HOP CONNECTION

4.5 CALL CONNECTION CONTROL FOR LOCAL CALL

When satellite channels are applied to transit trunks between switching systems of ZCs, the SXU deals only with transit calls. But when they are applied to local trunk portion between UC and GC, the SXU must deal with supplementary service calls and special number calls , such as 1XY and 0ABO.

As each gateway switching system (GS) deals with the selected service calls according to the originating subscriber area, the SXU connects each special call to the closest GS after identifying whether the call is special or not. In particular, the SXU is required to connect each special call to the closest GS in order to connect special calls of all UCs and GCs. Therefore, the originating office classification which can identify whether the originating office is a local switching office with a final trunk only or a general office is needed. The route to the gateway switching system is analyzed and decided in the SXU on the basis of this originating office classification. (Figure 10)

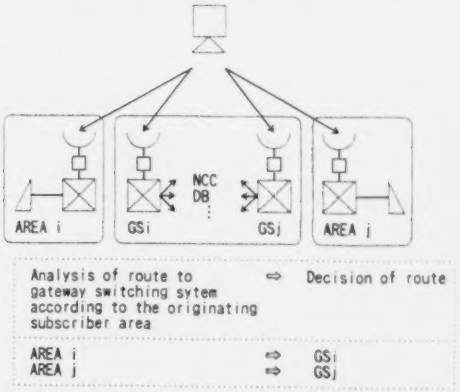

Fig. 10 DECISION OF ROUTE IN SUPPLEMENTARY SERVICE CALL

4.6 APPLICATION TO DIVERSIFIED SIGNALING SYSTEMS

To extend satellite communication systems to local switching systems in UCs or GCs, a channel associated signaling capability is required in addition to a common channel signaling capability. To apply call-oriented demand-assignment satellite channels to the channel associated signaling system, a satellite channel interface unit (SIU), which converts a continuous line signal to/from a frame type signal between an LS and an associated ES, has been proposed.

To receive an address signal in a speech path, the SXU connects the speech path between the SXU and LS directly by using a demand-assignment satellite channel. This method has advantages, such as efficient usage of satellite channels and miniaturization of signal conversion equipment. But as a number of procedures for receiving/sending signals via satellite channels are required, this method has a slight disadvantage: that is, post selection time becomes longer because of the delay in satellite channels and processing time for signal conversion. Figure 11 shows the system configuration for application to the channel associated signaling

system. Figure 12 represents the call connection control procedure . Post selection time is expanded by about 3 seconds as shown in Figure 12. Therefore, application of the channel associated signaling system to the satellte communication system must be minimized as much as possible. If the terminating switching system has CCS No.7 capability, we should use CCS No.7 in the terminating switching system by using the conversion capability of the SXU between CCS No.7 and the channel associated signaling system in order to shorten post selection time.

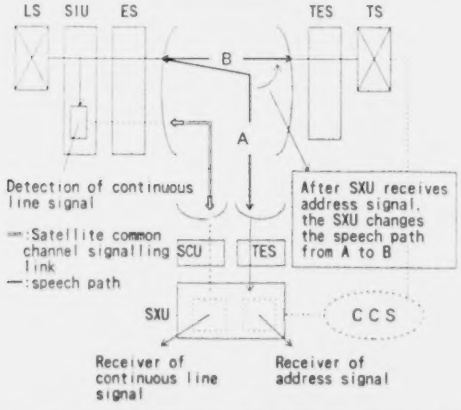

Fig. 11 SYSTEM CONFIGURATION OF DYANET TO APPLY CALL-ORIENTED DEMAND-ASSIGNMENT SATELLITE CHANNELS TO THE CHANNEL ASSOCIATED SIGNALLING SYSTEM

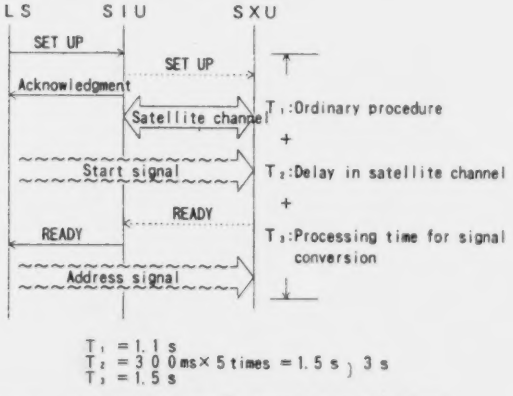

Fig. 12 CALL CONNECTION CONTROL PROCEDURE OF THE CHANNEL ASSOCIATED SIGNALLING SYSTEM

5. CONCLUSIONS

This paper proposes an advanced network control system for ISDN subscriber and trunk applications in a satellite communication system. The key technology is a centralized network control system to ensure single-hop connection and efficient satellite channel utilization. The network control system consists of multiple satellite channel control units (SCUs) that manage satellite channel resources and establish satellite channels between earth stations (ESs) and a satellite communication transit exchange unit (SXU). The SXU is connected to transit and local switches via Common Channel Signaling system (CCS) No. 7 .

Functional requirements of the proposed network control system for expanding the application of satellite communication systems to the ISDN subscriber and local switching systems are discussed and proposed following the network control technologies. Some features are as follows.

I) Integration of multiple satellite communication systems: Several kinds of satellite communication systems that differ according to transmission speed, communications satellite, and so forth, are used in ISDN. Satellite channels are handled by the satellite communication system through the SCUs. The SXU requires multiple SCUs control and routing control based on the matching operation of the satellite communication system. Here, a new translator that can select a direct route to the farthest-end ES from the originating side among multiple satellite communication systems is discussed.

II) Combination of a subscriber access portion and a transit circuit via a satellite channel: The single-hop connection between any two earth stations (user-user ESs, user-transit ESs, and so on.) should be ensured to maintain speech quality. A local switch (LS) with a ISDN subscriber module performs routing control on subscriber circuits and the SXU performs routing control on transit circuits. Depending on the routing control signals sent from LS to the SXU, the SCU establishes and releases satellite channels between ESs on a call-by-call basis. To provide ISDN services on a single-hop basis, a new change connection control using CCS No.7 ISUP and the SXU farthest-end routing, which offers direct connections between satellite subscribers or between a satellite subscriber and a transit circuit of LS/TS, is proposed.

III) Satellite channel switching control for local switching systems: To extend satellite communication systems to local switching systems, the SXU is required routing control and connection control for PSTN supplementary services (operator access calls, new common carrier access calls, and so on.) and the channel associated signaling capability for the connection of analogue switching systems. The translator that routes supplementary service calls to gateway switches according to the originating subscriber area is discussed. To achieve the application of call-oriented demand-assignment satellite channels to the channel associated signaling system, a Satellite Channel Interface Unit (SIU) which converts a continuous line signal to/from a frame type signal between an LS and an associated ES is newly proposed.

ISDN CENTREX APPLICATIONS IN A LARGE MULTINATIONAL COMPANY

A. Hastings, J. Heneghan, T. MacGregor, L. Steffes, R. Thompson
AT&T Bell Laboratories
Naperville, IL, USA

ABSTRACT

This paper presents seven innovative, cost effective, and productivity enhancing ISDN applications in, or soon to be in, everyday use at the AT&T Bell Laboratories and Network Systems in Naperville and Lisle, Illinois. The site accommodates over 12,000 engineers, managers, and support staff. This six building complex is the largest ISDN Centrex installation in the world. It utilizes 14000 5ESS Switch Basic Rate Interface lines to provide service. The primary work done at the site involves producing Network System switching products.

ISDN provides foundations for the applications described within this paper. Several applications use off-the-shelf Customer Premises Equipment; others use prototype equipment. Each application addresses a specific communications need. These applications represent only a small sample of possible uses of ISDN.

1. Introduction

The future of Integrated Services Digital Network (ISDN) in the US and around the world is being viewed with increasing optimism based on the recent developments in terminal portability, increased deployment, network evolution, and ISDN CPE and applications. This paper provides an overview of six innovative, cost effective, and productivity enhancing applications in, or soon to be in, everyday use at the AT&T Bell Laboratories and Network Systems sites in Naperville and Lisle, Illinois. That complex is the largest ISDN Centrex site in the world with over 14,000 5ESS® Switch Basic Rate Interface lines. Applications presented in this paper include:

— ISDN multipoint,

— ISDN printer sharing,

— ISDN terminal interface card for multiple data sessions,

— ISDN host interface for terminal sessions,

— ISDN telephone call control via data terminal,

— Video Conferencing,

— ISDN service direct to employees' homes.

Each application is described including capabilities, benefits, configuration diagrams, and CPE required.

2. Background

The Indian Hill (IH) Bell Laboratories and Network Software Center (NSC), located in the suburbs of Chicago, is a major AT&T research and development facility. This campus consists of six large office buildings and houses about 12,000 engineers, managers, and support staff. The primary work efforts at this complex consist of large scale switching systems software and hardware design and development, including both the US and international versions of the 5ESS Switch.

In the late 1980's the IH telecommunications organization determined that the existing multiple PBX system did not allow flexibility for growth and user services. They decided to evolve to one integrated system to save administration costs, allow flexibility for growth and provide features across all buildings. After reviewing PBX and Centrex options, the telecommunications organization chose ISDN Centrex from Illinois Bell (IBT) as the best solution to meet all of these needs. AT&T contracted with IBT for 5ESS Switch ISDN Centrex service beginning in April of 1989. This full scale ISDN installation provides service to all six buildings and serves over 14,000 Basic Rate Interface (2B+D BRI) lines (Figure 1). This complex ranks as the largest ISDN Centrex service in the world.

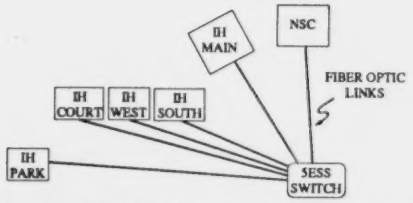

Figure 1. IH/NSC Office Building Configuration

ISDN services such as calling name display, centralized voice messaging, increased conference capabilities, and other enhanced voice features provides a significant improvement in the telephony environment. In addition to these services, new applications enhance the desktop environment, provide video conferencing, and extend the work environment to the home. The following sections describe these applications.

3. Desktop Environment Enhanced by ISDN

The engineer's environment at the IH and NSC sites

730

consists of two person offices where each person has a desk, telephone, and a terminal or workstation for interacting with the software development environment (SDE). The SDE platform is a network of mainframe host computers running the UNIX® Operating System. Traditionally, engineers connect their terminal or workstation to host computers via an asynchronous data network.

The introduction of ISDN to the engineering desktop provides opportunities for enhancing the development environment by blurring the boundaries of voice and data communication. The following ISDN interfaces contribute to lower costs and improved communications.

3.1 Multipoint Basic Rate Interface

Multipoint BRI allows up to eight users to share the 2B+D of a single BRI. One user can access both B channels for voice and data calls, or two users can each access one B channel for voice or data calls. All eight users always have access to the D channel for packet data. Unique alerting identifies each user's calls, and users are prevented access to other's calls. Both users can be active on a voice call and multiple data sessions without blocking the other in any way.

Currently, multipoint BRIs supply telephony service to over 200 two-person offices at IH/NSC. Figure 2 shows a multipoint office configuration.

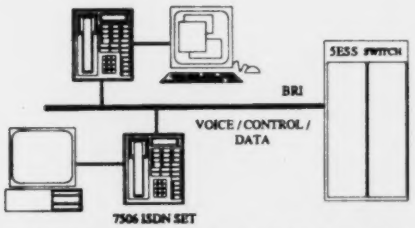

Figure 2. Multipoint BRI Configuration

The multipoint interface adds value by serving multiple users with a smaller amount of switch and building wiring resources. IBT made a two person multipoint BRI available at a cost significantly less than two BRIs.

3.2 ISDN Printer Sharing

AT&T employs a variety of operating systems at this campus. These include DOS, Apple, UNIX®, and IBM.

Traditional mainframe UNIX based systems provide pre-ISDN printing capabilities at IH/NSC. Using asynchronous data networks and Local Area Networks, the UNIX based systems directly control printing. Engineers use the UNIX based system to do software development, support production work, and to do traditional UNIX word processing. If engineers need to develop or co-develop a document, traditional UNIX word processing is still a popular choice.

Often engineers and people in the business management groups use PCs to author individual documents. They use DOS or Macintosh® based software application programs. Such programs include Wordperfect®, Word®, Drawperfect®, Harvard Graphics®, and GEM®. Within this environment, the DOS user community finds ISDN printer sharing gaining rapid acceptance. Printer sharing is economical and useful.

Two vendors supply software applications which allow printer sharing via an ISDN connection. They are Excellnet© and Manylink©. Their packages make ISDN D channel packet look like a local 19.2K serial channel having characteristics of the PC's serial connection. Each package enables a dial-up connection between PCs and supports remote access to a printer connected to a PC. The PC must be running Excellnet or Manylink. The user has the option on whether they would like to dedicate the PC to only service incoming print job or whether they would like to have the PC to concurrently service incoming print jobs and a DOS application. Figure 3 shows how printers can be connected via ISDN.

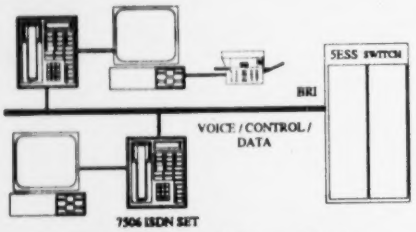

Figure 3. ISDN Printer Sharing

The performance of the ISDN connected printer is comparable to those printers who interface to a PC using a direct serial connection. Naturally, the performance is less than that of a parallel connection. As a result, ISDN connected printers can be sensitive to amount of data associated with the print job. Large ASCII-based print jobs have excellent performance. Large bitmapped print jobs such as a graphics file run slow. Application software provides options which may improve performance. For example one might have the application software produce a lower-resolution graphics print job. Another approach would be to send graphic print jobs to an ISDN connected Postscript printer. Postscript printers provide performance improvement up to 40% for large bitmapped print jobs. People within the work place share laser printers with and without Postscript capabilities. Additional performance improvement is possible when remote printer applications begin to utilize a ISDN B channel packet link across ISDN. This link provides serial speeds up to 64K. The ESP® board produced by Hayes® Microcomputer would enable high speed ISDN based serial data transfers.

ISDN printer sharing is a popular application at the IH/NSC complex. It provides a cost effective solution for providing printer service for small communities of PC users. It provides satisfactory printer performance within the small PC user community. As additional Customer Premise Equipment and software application become available, higher data transfer rates will be available and will enable ISDN printer sharing to approach the performance level of a parallel port printer. This will increase the number of users who share the printer and will continue to increase the number of user communities.

3.3 Multiplexed ISDN Terminal Interface

The 7506/7507 ISDN set provides voice service and data network access. Data network access requires the Asynchronous Data Module (ADM) option. Engineers at IH/NSC use the ADM to connect terminals, PCs, or workstations to host computers using D channel packet switching. The ADM provides host connections for relatively low cost. However, it does not support multiple concurrent connections. Multiple concurrent connections are important in the highly distributed development environment at IH/NSC.

Many engineers use the AT&T 730 Multitasking Terminal with Graphics (MTG). The MTG is a high resolution, multi-window, multi-host, programmable graphics terminal. It allows up to three asynchronous interfaces for host connections and can display seven virtual terminal windows for each host connection. This makes is an attractive solution to the distributed host connection problem. This terminal is in extensive use at IH/NSC, with over 4000 in place as of mid-1991.

Since the introduction of ISDN service, many users of the 730 MTG began to consider how this terminal and ISDN could be combined to provide even greater capabilities. Their solution was the ISDN Data Module (IDM). The IDM fits into an existing expansion slot in the MTG. It provides an ISDN BRI connection to the switch and a second BRI connection to an ISDN telephone. Figure 4 shows the 730 MTG with the IDM card the attached ISDN set.

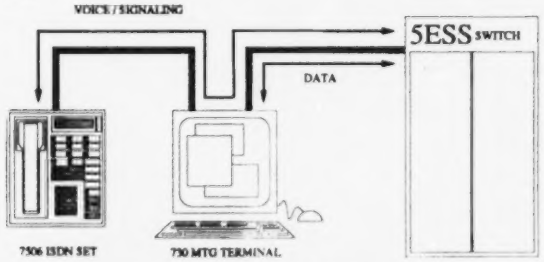

Figure 4. 730 MTG IDM Configuration

Specific benefits provided by the IDM include

- access to eight different hosts simultaneously,
- performance improvements of up to 300% compared to the asynchronous data network,
- reduced network connection costs and clutter.

There is no impact on the capabilities and operation of the voice ISDN set in this configuration. Users of the IDM card have been extremely enthusiastic about the benefits provided. Currently, over 2000 IDM cards are installed and in everyday use.

3.4 ISDN Host Interface

Prior to the implementation of ISDN at IH/NSC, a large asynchronous data network provided over 20,000 terminal and 20,000 host interface connections. At the time of the ISDN cutover, there was no cost effective mechanism to connect host computers to ISDN. The solution was to develop a T1 based interface that uses X.25 on the separate DS0 channels. Each channel supports multiple terminal sessions. This interface uses a standard 5ESS Switch feature known as X.25 Access on a T1 (XAT). The T1 terminates on a SUN4-based Front End Processor (FEP). The FEP connects to the UNIX mainframe via an IBM compatible channel interface. This full duplex connection supports asynchronous terminal to host sessions at rates up to 19.2 kbps. This X.25 host interface provides an end-to-end error and flow controlled connection required for the windowing application benefits discussed in the previous section. Figure 5 shows the ISDN host interface.

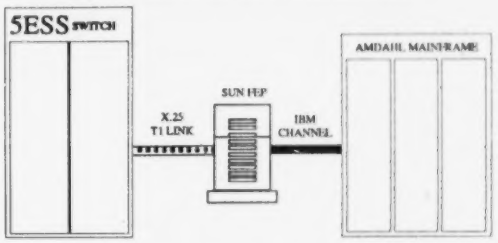

Figure 5. ISDN Host Interface Configuration

Currently, 20 mainframe hosts have one or more ISDN host interfaces supporting terminal sessions. Over 300 simultaneous terminal sessions are supported on each host interface. In the future, we expect this configuration to support all terminal-to-mainframe traffic at the IH/NSC site.

3.5 Voice Feature Control Applications

The serial interface to the 7506/7507 ADM provides access to data connections on the network. In addition to providing the data connection, the ADM can be used to control voice features associated with the 7506/7507 set. The latest generation ADM implements an extended Hayes-compatible Application Programmer Interface (API) protocol that allows complete control of voice features on the set. API applications provide significant extensions of voice features. Figure 6 shows a windowing terminal connected to the ADM via the serial port in the base of the ISDN set.

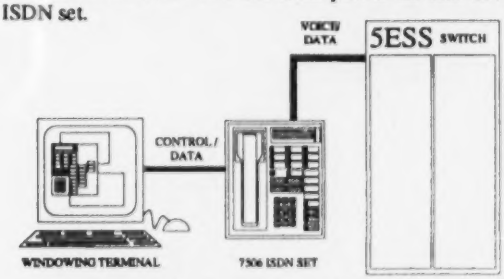

Figure 6. Voice Feature Control Configuration

The API specifies a rich set of control and status messages that a windowing terminal or PC application can use to

- monitor display messages, button presses, lamps, signals, network call progress, and call status;
- simulate button presses and display messages;

732

- control the speakerphone, lamps, alerter, and auxiliary equipment;
- provide access to "virtual" buttons not physically present on the set.

Currently, several applications based on API capabilities are in daily use at IH/NSC. They range from simple call tracking systems for help desk operations, to simulation of users exercising voice features on 5ESS Switch lab test models. By far the most popular application to date is a personal telephone manager that provides a graphical user interface to the usual voice features of the 7506/7507 set, with enhanced call management features. It runs under the UNIX Operating System on the 730 MTG terminal or any terminal running X Windows.

The graphical user interface of the personal telephone manager duplicates the layout and functionality of the 7506/7507 on the screen. Using the mouse pointing device to select a graphical button on the screen is equivalent to pressing the corresponding button on the phone. The user can move or delete buttons from the screen. The user can create buttons to provide new functionality, such as dialing calling card numbers or feature access codes. Pop-up dialogue windows provide on-line help or special functions such as electronic directory query. For incoming calls, the incoming caller identifier (ICLID) is used to retrieve and display detailed information on the calling party from corporate databases.

The user may define pop up speed call menus in a startup file. Incoming and outgoing calls may be logged in a file, whether or not the call was completed. This call history is available through special speed call menus, providing quick access to calls missed. If a phone number shows up in an electronic mail message or other on-line document, it may be selected with the mouse and dialed automatically.

Other potential capabilities for the personal telephone manager include

- call notebook, where pop-up windows manage notes pertaining to calling or called people;
- personal conference call management, where conference calls are set up under program control;
- call forwarding to a pager with touch tone interface;
- incoming call screening for per-caller forwarding or ringing patterns.

Software development is the primary activity at IH/NSC, and the computing environment provides the ability to communicate textual information among the development community. The ADM API provides a long sought link between the computing environment and the voice communication environment, enhancing both worlds.

3.6 The ISDN Workstation

Combining the capabilities described up to this point results in an ISDN work environment (Figure 7) that is cost effective, has high performance, is user friendly, and provides the tools to allow the engineer to be more productive.

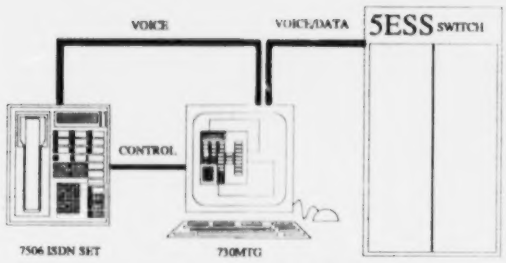

Figure 7. ISDN Workstation

4. Videoconferencing

Videoconferencing is touted as a big cost saver because it reduces travel expenses. Actual savings vary for each company, depending on the amount of travel eliminated. At IH/NSC, videoconferencing saves time, adds efficiency to day-to-day operations, and enhances communications amongst members of the work community and with customers. Technology has progressed to the point where combined voice and video signals can be compressed to 128kbps. As a result, videoconferencing between IH/NSC and other locations can be economically provided. Two services take advantage of this economical bandwidth. One service is conference room videoconferencing. In addition, a service trial of personal videoconferencing is in progress.

4.1 Personal Videoconferencing

Personal videoconferencing is face-to-face video where each person looks at the other's face. Motion during this style of communication is limited making the video signal suitable for compression. The personal videoconferencing service uses requires two B channels. One B channel is dedicated to video, the other is dedicated to audio. This allows videoconferencing across 64K B channel. Prototype CPE is used for this trial.

In the first half of 1992, twenty personal video phones will be set up among corporate managers between different buildings at IH/NSC. Each manager will have a video unit on their desk. Figure 8 shows the components of the unit.

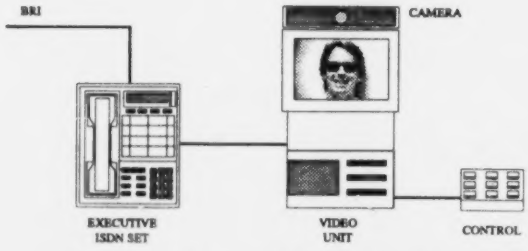

Figure 8. Personal Video Configuration

The video unit contains a color liquid-crystal display, camera, and control key pad. The unit has two video transmission modes: full motion and high-resolution still frame. An optional graphics stand can be used with the phone to provide the remote display of documents, diagrams, and pictures.

The personal video trial will last for 12 months. During this period of time, usage data will be collected and analyzed. Expected benefits of this service include

- saving of executive travel time between offices,
- enhanced communication resulting from eye-to-eye contact, and
- the ability to simultaneous view the same visual information.

4.2 Conference Room Videoconferencing

Conference Room Videoconferencing is group to group interactive video conferencing where people in geographically separated sites see and hear each other in real time. In addition, diagrams or transparencies shown in one room can be viewed in the far room. The advantage of a videoconference room network grows as the distance between conference sites grows and greater travel time and costs can be avoided. As mentioned above, the video and voice compression techniques have progressed to the point where acceptable signals can be transmitted on 112 or 128 kbps links. AT&T has maintained higher bandwidth video systems at major sites for several years. Unfortunately, the cost of these systems and links have limited the availability and systems are overbooked or not installed in the desired sites. The lower bandwidth systems have lower cost and are easier to install in a timely manner.

The conference room video system consists of a video camera, conference microphone, video screen, control devices and a document stand. The system can be equipped with additional cameras and video screens if desired. See Figure 9 for the base configuration of the conference room video system.

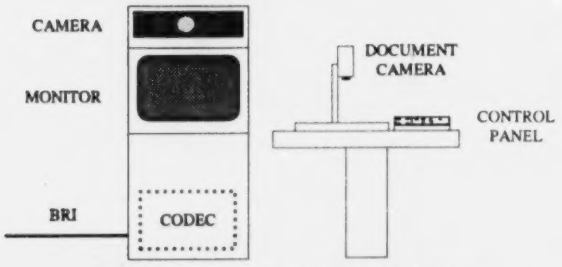

Figure 9. Conference Room Video Station

Currently the lower speed conference room video system consists of systems at IH/NSC, Bell Laboratories sites in New Jersey, and a few AT&T international offices. There are plans to expand the video network to include other Bell Laboratories sites, additional international sites, and possibly customer sites.

Connectivity within the IH/NSC site is provided by the ISDN. Connectivity to New Jersey and international sites are provided by the AT&T Accunet® Switched Digital Service (SDS) accessed via ISDN. ISDN provides a switched access to the Accunet SDS. Switched access allows the concentration of traffic onto access facilities thereby reducing the number required and the cost compared to dedicated facilities. Furthermore, using ISDN as the access vehicle allows the addition of video systems throughout IH/NSC without the long lead time often associated with the installation of dedicated facilities.

5. ISDN Service to Employee's Homes

With advances in ISDN applications and CPE like those described in this paper, ISDN service to people's homes is an exciting option to consider. This service is both economical and technically feasible today. Indeed, it is a reality for many AT&T employees at IH/NSC.

One challenge to offering this service on a subscription basis is its limited availability on switches that services our employees homes. Initially less that 15% of our employees were eligible for the service. If people were serviced by an RSM or the loop did not qualify based on distance, they could not get the service. Ameritech plans to expand ISDN service offerings in 1992. We expect many more people will become eligible in that time frame. Further, Ameritech announced at the ISDN Forum in Washington, D.C. in July, 1991 that it plans to have 87% of its lines configurable with ISDN by the end of 1994.

The key benefit of this service is the high speed data access. Placing an MTG terminal equipped with an IDM card in an employee's home provides them with 16 kbps data service to the host computers resident at the work location. Individuals who do not have the IDM application at home use 9600 bps service through the ADM RS232 option on the 7506 ISDN telephone. By increasing the data rate from 1200 or 2400 bps to 9600 bps or 16 kbps, this service makes terminal work from the home equivalent to facilities at work. Working from home provides a highly productive environment, free of the interrupts commonly experienced in the work environment. Employees with ISDN service are better able to meet their work commitments without having to stay late or spend their weekends in the office.

Service to the home was particularly useful in the following cases:

- Staff who are on call in support of major computing facilities such as labs or major computing facilities.
- Field support staff who are on call and need terminal access to rapidly resolve customers' problems.
- Staff who need out of hours terminal access to computers or switches at other locations.
- Staff where flexibility is needed due to family situations (such as children or elder care situations).
- Staff or managers who do several hours per week of terminal work at home.

The cost of ISDN services compares favorably with the cost of modem pool service. ISDN service is superior to modem pool service in the areas of reliability, throughput, and functionality. For these reasons, ISDN is the preferred mechanism for providing data service to employees homes. The X.25 Closed User Group (CUG) mechanism provides security for this service. If a user is not a member of the CUG, access is denied. The service is supported by provisioning and billing mechanisms provided by the local telecommunications organization in conjunction with

Illinois Bell Telephone.

This service opens the door to providing a rich variety of applications to employees at their homes. This includes video using narrowband video equipment that is becoming available today.

6. Summary

This paper presents seven innovative, cost effective, and productivity enhancing applications in every day use at the IH/NSC AT&T Illinois facility.

Multipoint allows up to eight users to share a single BRI's 2B+D channels. It requires fewer switch and building wiring resources. IH/NSC uses this interface to provide a cost effective office configuration. Two people share one BRI to meet their voice and data needs.

ISDN provides a cost effective way to provide relatively high speed remote printing. The advantage to ISDN is the ability to share the costs of the data connection with a voice connection.

ISDN substantially improves the desktop environment at IH/NSC. The ISDN Data Module (IDM) significantly expands the 730 MTG terminal's ability to connect simultaneously to different hosts computers. Before the IDM, the 730 MTG could simultaneously connect to up to three hosts. This required two additional terminal's serial cards and three access ports from the Asynchronous data network. The IDM terminates the BRI directly and allows each users access to eight different hosts simultaneously using the D channel. The ISDN Host Interface services terminal to host sessions for the majority of users. The Host Interface uses a standard 5ESS Switch feature known as X.25 Access on a T1 and SUN4-based Front End Processor. Each host interface supports over 300 simultaneous terminal sessions. The interface provides each terminal session a full duplex 19.2 kpbs asynchronous connection and end-to-end error and flow control. The ISDN Voice Feature Control Application uses the graphics ability of the 730 MTG and APIs of the 7506 ISDN set to provide alternate way to access 5ESS switch features. Using a mouse pointing device, the user can select buttons on a screen layout of the 7506 set. This action provides the same result as physically pressing buttons on the 7506 ISDN set. For incoming calls, ICLID can be used to retrieve and display detailed information on the calling party from the corporate data base. Incoming and outgoing calls may be logged. Missed calls may be retrieved. When reading e-mail from the host computer, one can use the mouse device to select and dial the telephone number in the e-mail address. The ISDN Workstation combines the IDM and Voice Feature Control capabilities to provide a high performance and user-friendly desktop environment with additional connectivity and tools to allow the engineer to be more productive.

Technology has progress to the point where combined voice and video signals can be compressed to 128kbps. Two services in use at IH/NSC take advantage of this economical bandwidth. Personal videoconferencing is a trial service set up amongst twenty corporate managers to provide face-to-face video/audio communication. Expected benefits include reduce travel time and enhanced communications. Conference room videoconferencing provides group-to-group interactive video where people separated by distance see and hear each other in real time. Multiple sites are set up and operational. ACCUNET Switch Digital Service interconnect each using 112 kbps switch service. Expected benefits include reduced travel time, reduced cost to travel, and easy access to human resource when required.

ISDN service to employee's home is a reality for employees at IH/NSC. This service provides employees ISDN access to the full 5ESS production environment from home. Prior to ISDN service at home, employees connected to the 5ESS production environment via 1200/2400 baud modems. This restricted environment allowed low speed access to one host computer. With ISDN service, employees have high speed access to up to eight different hosts. Working at home provides a highly productive environment, free of the interrupts commonly experience in the work environment.

ISDN provides the foundation for several cost effective and productivity enhancing applications that are in widespread use at the IH/NSC. Some applications are provided via of-the-shelf products. Others have been developed as internal tools; hence, are not yet generally available. The concepts behind each application is consistent with ISDN switch features and can be provided via CPE on the market today.

7. Conclusion

ISDN provides a robust foundation that effectively handles a diverse set of communication needs within our large multinational company. ISDN delivers cost effective voice, data, and video that can be easily mixed and matched to meet many communication needs. The applications presented here represent a small sample of possible uses of ISDN. With these initial applications we begin building our future corporate communications environment. This work sets the stage for a shift in paradigm of how people communicate as we move into the 21st century. Only one's imagination limits the possible uses of ISDN.

Authors:

Alan Hastings received a BA in Mathematics in 1979 from Earlham College and a MS CS in Software Theory from Stanford University in 1985. He joined Bell Laboratories in 1982 where he has worked on switching system software, software tools, distributed computing environments, and ISDN application software. He is currently studying video teleconferencing in the Software Production Research Department in Naperville, Illinois.

Joe Heneghan received a BA CS from Southern Illinois University in 1979 and an MS CS from North Central college in 1989. During Joe's career at AT&T he has worked on various switching systems including 1AESS Switch, 4ESS Switch and TSPS. In addition, he has provided customer support for AT&T Computer Systems Networking Products. He is currently a Member of Technical Staff in the ISDN Systems Integration Group.

Terry E. MacGregor received his BSEE and MSEE from Bradley University in 1971, 1972 and his Phd CS in 1979 from Northwestern University. He joined AT&T Bell Laboratories in 1978 as a Member of the Technical Staff responsible for system integrity software development on the first 5ESS. In 1983, he became Supervisor and provided customer support for the 5ESS. In 1986, he became a planner and developer of ISDN software for Data Services on the 5ESS. Mr. MacGregor planned and co-developed many of the Packet Data features on the 5ESS. He is a member of the IEEE and an associate member of Sigma Xi. His research interests include data networking and large scale software development processes and methodologies.

Lorene Steffes is Department Head of the 5ESS® Switch Special Features Department at AT&T Bell Laboratories, Naperville, Illinois that implements 5ESS Switch features on deployed 5ESS Switch software. She also manages an ISDN Applications Project focused on using ISDN applications at Bell Laboratories in Naperville. Since joining AT&T in 1982, she has provided systems programming and support of Large Mainframe UNIX® Systems; supervised a group responsible for providing AT&T required kernel enhancements to Amdahl's UTS®; led initiatives to set directions for the evolution of the AT&T R&D computing environment; and headed the Software Development Systems Department responsible for systems engineering, planning, development, verification, training, and customer support of the tools used by the 5ESS Switch developers. Her formal education consists of a BS in mathematics (1968) and an MS in Computer Science (1982). Both of her degrees are from Northern Illinois University.

Robin Thompson received a B.S. in Mathematics from Manchester College in 1983 and a M.S. in Applied Mathematics from Clemson University in 1985. He began his career with Bell Laboratories in 1985 as a Systems Engineer for the 5ESS Switch and has been responsible for ISDN applications development and customer support for accounts such as MIT, Merrill Lynch, Boeing, Tenneco, Duke University, and the ISDN implementation at the IH site. Following the implementation of ISDN at Indian Hill, he led an ISDN applications forum chartered to investigate and champion ISDN applications for use at Indian Hill. He is currently in the International 5ESS Wireless Applications group and is responsible for data applications planning.

'I-Board 64' for Personal Computer Communication over ISDN

Tomiji Soga Kazuhiro Nomoto Taizoh Shutoh

NTT PC Communications Inc.
Tokyo, Japan

ABSTRACT

NTT PC Communications Inc. provides personal computer communications services conforming to CCITT X.400 series Recommendations. In response to the growing trend towards file transfer-type and interactive database access-type communications, we have developed an ISDN communications terminal utilizing the 'I-Board64', a personal computer communications board allowing transmission over ISDN. It supports all three ISDN communication modes, and enables high-speed data transmission.
This paper describes the background to ISDN terminal development, the state of Japanese standardization for ISDN communications, and the configuration and performance of the personal computer communications terminal over ISDN.

1. INTRODUCTION

As a subsidiary of Nippon Telegraph and Telephone Corporation (NTT), NTT PC Communications Inc. began communications network service for personal computers (PCs) in November 1986. Its network is referred to as the NTT PC Network. Conforming to CCITT X.400 series Recommendations, the NTT PC Network provides value-added network services such as mail boxes, bulletin boards, and realtime connections.

To speed introduction of services and facilitate expansion, system development and introduction were carried out in several phases. Since the first system was established in 1985, functionally expanded systems to enlarge the communication area economically and enable the provision of additional services were introduced in 1988, 1989, and 1990.

The NTT PC Network is mainly for business use, and currently accommodates 30,000 subscribers including 3,000 companies. Study of usage patterns shows two main tendencies. One is file transfer-type communications requiring high-speed data transmission capability. The other is interactive database access-type communications, in which long communication time puts a priority on economy.

NTT's ISDN service started in 1988, offering both high-speed data transmission and the capability of packet-switched service at a low monthly basic tariff. NTT PC Communications' ISDN communications terminal has been developed to process effectively file transfer and interactive communications.

2. THE NTT PC NETWORK

2.1 NETWORK SYSTEM CONFIGURATION

The network structure of the NTT PC Network is shown in Figure 1. As shown in the figure, the message switching center can concentrate traffic from various distances and of different volumes. Users can select the most convenient type of connection.

Many users access the network through the PSTN utilizing analog modem adapters based on the Japanese Unified Standard for Telecommunications-Personal Computers (JUST-PC). Those adapters enable 4,800bps data transmission. A higher-speed V.29 JUST-PC modem adapter, available from NTT PC Communications since summer 1991, gives 9,600bps data transmission speed. The NTT PC Network will soon support communications using new high-speed adapters.

The NTT PC Network operates throughout Japan. We have two message switching centers in Tokyo, and twenty access points have been installed in major cities. Another nineteen access points will be brought into the network by Spring 1992. Private packet-switched networks and leased lines connect access points to the message switching centers. The existing network distribution is shown in Figure 2.

2.2 NETWORK SERVICES

The NTT PC Network provides the following services.

- Mail box service
  All basic service items prescribed by CCITT Recommendation X.401 are provided. Forty of

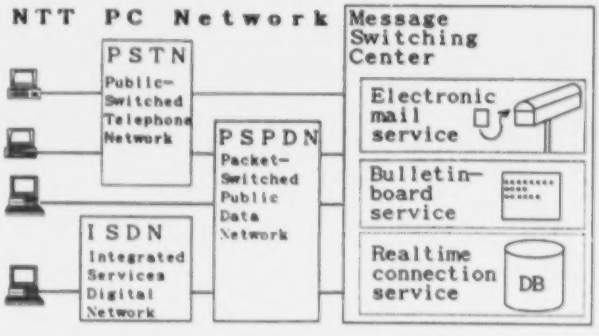

Fig. 1 Network Structure

Fig. 2 Existing NTT PC network distribution

the 48 prescribed options are also supported, including multi-destination delivery, deferred delivery, receipt notification, and media/code conversion services. When direct delivery is made to a G3 facsimile, message text code is automatically converted to graphic image data.

- Bulletin board service
  Users can exchange information using a common memory area based on JUST standards. This service is regarded as an expansion of the Message Handling System (MHS).

- Realtime connection service
  Realtime connection is provided in addition to store and forward services. These services are useful in accessing the information provider's computer centers in the NTT PC Network.

- Security
  Information stored in message switching centers must be protected against any illegal access or violation. Log-in authentication, closed user groups, and notification of most recent access time are designed into the NTT PC Network.

2.3 OBSERVATIONS ON OPERATION

Figure 3 shows distribution of current service usage. Although the bulletin board service made up about 80% of use during the early part of 1988, it presently comprises just over half. The share held by our electronic mail service has increased markedly to 41% from 14.5% in 1988. As users often send binary files via electronic mail, there are huge requirements for file transfer in the NTT PC Network. While high-speed data transmission is available with a V.27ter 4,800bps analog modem, a more economical high-speed data transmission line is required.

Figures 4 and 5 show the distributions of communication time and message lengths. Average call time is seven minutes, a 1.6 times increase over the 1988 figure. While average message length of bulletin board access is twice as long as in 1988, the peak remains around 2KBytes. According to the results of a service usage study, interactive communications are often utilized in bulletin board and realtime connection modes. In interactive communications, a user first checks guidance messages or scans data on his screen. After entering some keywords and transmitting them to computer centers, succeeding messages will be received from computer centers and displayed. Because communication takes considerable time relative to information volume transmitted, the long connection time highlights the need for economy.

As mentioned above, users trend to communicate either through file transfers or interactive transactions. An additional requirement is easy change of access lines, as users want to use both file transfer and conversation type services. For these requirements, ISDN is currently the best solution. ISDN makes available both a high-speed B-channel circuit-switched mode and a B/D-channel packet switched mode. These modes are selected not only call by call, but are also usable simultaneously.

3. STATUS AND BENEFITS OF ISDN SERVICE

NTT has offered its INS-Net 64 basic interface service since 1988, INS-Net 1500 primary rate interface service since 1989, and packet-switched service since 1990. By August 1991, NTT's ISDN accommodated 57,800 lines, up from only 114 lines when the service started. Supported by the falling prices of ISDN peripheral equipment, the number of ISDN users has begun to increase dramatically. With NTT's announcement of ISDN expansion to 2,060 service areas by the end of 1991, the number of users is expected to increase to about 750,000 by Spring 1995.

ISDN has proved its worth to users in a number of ways. For PC communications, ISDN is capable of high-speed data transmission at the same tariff as the analog telephone network. ISDN offers 64Kbps transmission against a maximum 9,600bps in the existing telephone network. This feature is expected to lead to such new ISDN applications as multi-media communication which requires massive data transfer.

In the packet-switched mode, ISDN benefits users through a structure where charges are proportional to information volume, and monthly basic charges are low. Since many users converse with computer centers in online mode, it is desirable to be charged by mass of data transmitted rather than by communication time and to be offered a low monthly basic charge. The proportional tariff of NTT's ISDN packet-switched service is the same as that for Digital Data Exchange Packet (DDX-P) service. The monthly basic charge for the addition of packet-switched service is only about U.S.$8 at minimum configuration, while that of the DDX-P is relatively high. The difference in the monthly basic charge has been a factor behind the increase in ISDN packet-switched service use.

As the number of ISDN users has begun to increase dramatically, the price of ISDN equipment has begun to fall. Furthermore, ISDN will soon be available in all parts of Japan. A continued increase in the number of ISDN users will accelerate the drop in the equipment price resulting in even more ISDN users. From this viewpoint, the development of the ISDN communications terminal for personal computers comes at the right time.

4. JAPANESE ISDN APPLICATION STANDARDS

In conformity with CCITT I-series Recommendations, the Telecommunication Technology Committee (TTC) specified Japanese national standards for ISDN in May 1987. They prescribes the OSI Layers 1 to 3 protocols needed for ISDN terminals to inter-work with the network. Based on TTC ISDN standards, some Terminal Adapters (TAs) and add-in type communication boards have been developed.

For end-to-end communications, a high-layer protocol for application programs is required, and has been specified by manufacturers. To guarantee inter-operability among terminals and provide economical communications, high-layer ISDN communication protocols must also be standardized. To support the existing OSI applications, standardization must be based on OSI reference model.

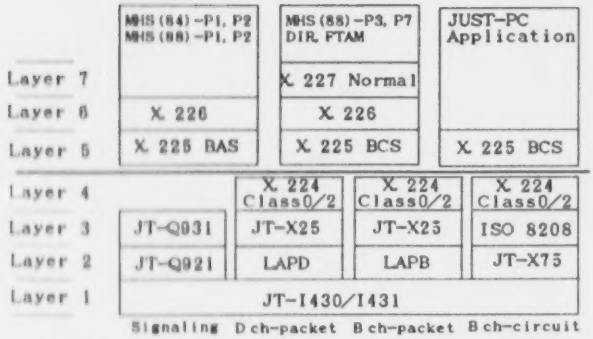

Fig. 6 Protocol structure of JT-PD00

In April 1990, the TTC announced its JT-PD00 series standards specifying OSI profiles for ISDN applications. The JT-PD00 series covers protocol sets from Layers 1 to 7, and is widely applicable to standardized applications such as MHS, directory (DIR), and FTAM.

Figure 6 shows three communication profiles of the JT-PD00 series.

- OSI profile
  The fundamental profile for OSI applications such as P3/P7 (MHS protocols specified in 1988), DIR, and FTAM. It is based exclusively on OSI protocols.

- MHS inter-operable profile
  For MHS functional standards specified by TTC, conforming to CCITT MHS Recommendations.

- JUST-PC profile
  For existing JUST-PC applications.

According to the type of communication path used, there are three types of profiles in Layers 1 to 4. One is for the D-channel packet-switched path, another is for the B-channel packet-switched path, and the last is for the B-channel circuit-switched path. Any higher-layer profiles can be combined with them.

5. ISDN COMMUNICATIONS TERMINAL

5.1 TERMINAL CONFIGURATION

The basic design principle in the ISDN terminal provides for high-volume data transmission. When a PC is the host processor, it is important to save processor power and memory space.

The configuration of the ISDN terminal is shown in Figure 7. An I-Board 64 extension card-type ISDN board is installed in a PC's expansion slot. The I-Board 64 is connected to a host

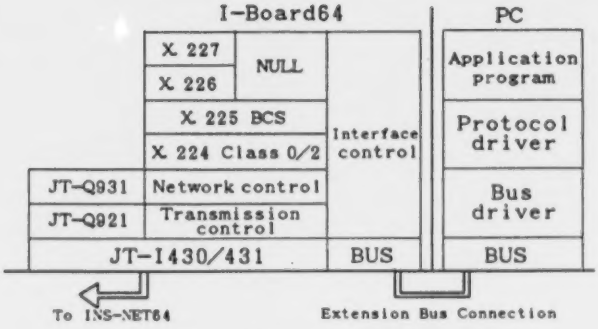

Fig. 7 Configuration of ISDN terminal

processor with a PC extension bus, giving high-volume data transmission between the I-Board 64 and the PC. A 16-bit microprocessor is embedded in the I-Board 64 to deal with Layers 1 to 7 protocol processing.

The first product of the I-Board 64 series supports OSI protocols up to Layer 5. The program interface between ISDN BIOS and application programs is specified according to OSI Layer 5 basic functions. We are now planning to develop two more types, one supporting Layers 1 to 3, the other supporting Layers 1 to 7 (ACSE).

Without the restrictions of ISDN call control and OSI protocol processing, personal computer applications can utilize all three communication modes. Therefore, applications can use 64Kbps high-speed data transmission in B-channel circuit-switched mode, and can also use the packet-switched mode on B and D-channels.

5.2 I-BOARD 64

The structure of the I-Board 64 is shown in Figure 8. The I-Board 64 consists of three blocks: a line signaling block, a control processor block, and a bus controller block. In the line signaling block, there are three signaling control LSIs (one LAPD and two LAPBs), allowing the I-board 64 to simultaneously communicate with all three communication paths. The bus controller enables the host processor in the PC to write and read the information to/from window memory in the I-Board 64. This means that the host processor can indicate commands to the control processor, and can also transfer data to and from the communication path.

A PCM CODEC is installed in the I-Board 64, permitting telephone calls with the attachment of a handset. Any two communication modes can be used simultaneously. For example, an operator can receive a telephone call on the B1-channel while accessing the computer center.

Many IC chips and electronic parts are required to control the ISDN circuit. By installing such parts on both surfaces of the board and packing its two sub-boards close together, the I-Board 64 occupies only one expansion slot.

5.3 APPLICATION PROGRAMS

5.3.1 PROGRAM INTERFACE

The NTT PC Network mainly supports JUST-PC applications, and much application software offers a JUST-PC command interface (CFU). For easy modification of much existing application software to ISDN products, the ISDN BIOS interface has been specified based on the CFU.

The CFU has been specified to control a single channel with a JUST-PC analog modem adapter, while many channel communications are simultaneously available in ISDN. An information header that indicates the communication environment (switching mode, channel number, etc.), is attached to the CFU commands.

5.3.2 ComTALK FOR NTT PC NETWORK ACCESS

As shown in Figure 9, two types of ISDN application software have been developed. One is ComTALK for electronic mail, the other is I-TALK64 for end-to-end file transfer. Using ComTALK, users can access the NTT PC Network for electronic mail and bulletin board services.

The software structure of ComTALK is shown in Figure 10. A modular technique is adopted to maintain software portability. ComTALK operates on MS-DOS, and consists of a human-machine interface module, an MHS protocol handler module, and a device driver module.

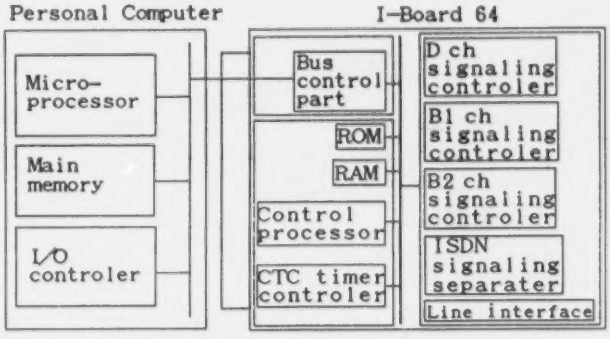

Fig. 8 Configuration of I-Board 64

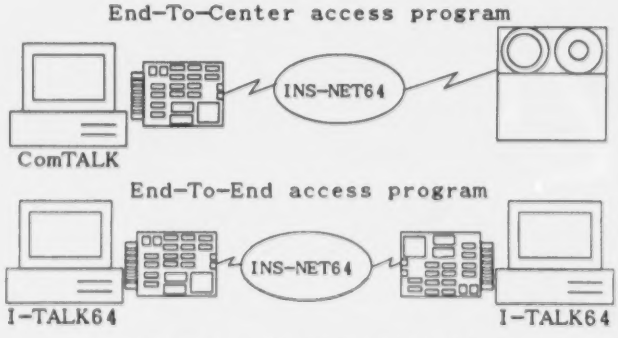

Fig. 9 ISDN applications

500

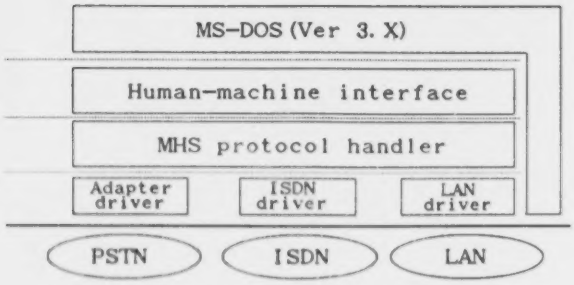

Fig. 10 Software structure of ComTALK

The human-machine interface module provides the environment for mail and bulletin board access. Supported by a cataloged procedure in the human-machine interface module, a user can customize communications procedures. Three device drivers are used for ordinary analog telephone networks, LAN networks, and ISDN. Choosing the appropriate device driver, ComTALK can deal with any of these networks. The protocol handler module supports JUST-MHS, which is specified in accordance with CCITT X.400 series Recommendations.

A packet-switched mode over the D-channel and B-channel is currently available, but the NTT PC Network does not support ISDN circuit-switched mode. A B-channel circuit-switched mode will be supported in the near future.

5.3.3 I-TALK64 FOR END-TO-END FILE TRANSFER

I-TALK64 has been developed to cater to demands for end-to-end file transfer. I-TALK64 directly connects an originating terminal to a destination terminal, and enables an operator to access files in the destination terminal. A circuit-switched B-channel path is usually adopted for high-speed file transfer, but I-TALK64 also supports packet-switched mode.

5.4 PERFORMANCE

Examples of data transmission rates are shown in Table 1. Results are excellent: maximum throughput is 62Kbps in circuit-switched mode, and 7 to 26Kbps in packet-switched mode. NTT's guaranteed level of packet-switched mode throughput is limited to 9.6Kbps.

Table 1 Performance of I-Board 64

	End-To-End	End-To-Center
D ch Packet	10Kbps	7Kbps
B ch Packet	26Kbps	10Kbps
B ch circuit	62Kbps	Now not supported

6. CONCLUSION

This paper has described the background to the need for ISDN communication, the status of ISDN services in Japan, and configuration and performance of the newly-developed ISDN terminal. The I-Board 64 is based on TTC JT-PDOO series standards, and can deal with all ISDN communication modes, in addition to offering communications software for electronic mail and end-to-end file transfer. Performance tests of the I-Board 64 have shown in an excellent 62Kbps data transmission rate.

The NTT PC Network currently only supports packet-switched mode, but it will soon be developed to support circuit-switched mode communications. The I-Board 64 will accelerate ISDN introduction.

Users of the NTT PC Network will benefit from the advantages of ISDN, including faster data transmission and packet-switched mode. The former will aid such file transfer activities as Electronic Data Interchange (EDI); the latter will be useful for interactive communications such as are used in a Strategic Information System (SIS).

To accelerate the introduction of ISDN services, standardization of the interface between ISDN BIOS and the application program is required in addition to standardization of the communication profile. It is also necessary to verify inter-operability among heterogeneous terminals. Those are important problems which need to be overcome.

GROWTH THROUGH INTEGRATION

BY
EDWARD R.SLACK
COMSAT MOBILE COMMUNICATIONS
WASHINGTON, D.C., USA

1. ABSTRACT

The communications industry has been impacted by three major factors which have caused it to evolve in the manner as we know it today--regulatory policy, technological change, and the development of computers for networking control. Because these changes are taking place at an increasingly rapid pace, it is important for a system to be flexible in design, thereby permitting new, more efficient means of satisfying customer requirements without necessitating replacement of the existing system and sending an earlier innovator into oblivion.

2. HISTORICAL APPROACH TO DEVELOPMENT

Historically, mobile communications systems have been developed on a stand-alone basis, designed for special applications, and only grudgingly interfaced with other systems. However, this was also true of virtually all communications, since most services evolved to satisfy a single user requirement. Because these systems were designed to meet specific requirements, they did not require standards, and due to existing regulatory policy, were permitted to expand as long as they did not interfere with other systems. Further, due to the slow rate of technological change, they tended to last for long periods of time because there was nothing better to replace them.

U.S. regulatory policy was also instrumental in promulgating this manner of development. Communications was considered a monopoly service, and most communications companies provided only a single service, focused on use of a single technology. AT&T was required to sell off its lucrative TWX service to Western Union Telegraph because it was considered a service more closely aligned with telex. Similarly, AT&T was also required to abstain from developing a data transmission service over its telephony network, with the record carriers being permitted to develop the service over separate networks, creating an artificial line of demarcation. Further, controls were imposed on users, restricting devices which could connect to carriers' networks, ostensibly for the purpose of protecting the network, but often protecting the carrier's revenues by enabling the carrier to impose additional charges for connecting such devices to their network.

3. THE CHANGING ENVIRONMENT

Beginning in the early 1970's, the nature of the telecommunications industry began to change. The U.S. Government, through the Federal Communications Commission (FCC), began to advocate competition. An upstart communications company, Microwave Communications, Inc., obtained approval to provide private line service between cities. Recognizing that this was only a small part of the potential market, the company pressed on and was soon able to provide long distance telephone service, although on a basis less favorable than the monopoly carrier, AT&T. In order to compete, this new entity had to offer substantially lower prices than the entrenched carrier.

During this same period, there were other changes also taking place. For a variety of reasons, including keeping AT&T from dominating communications technology, a new entity was authorized in 1962 to represent the United States in an international organization to be established to implement communications services via satellite. Based upon the controversy over how the company should be established and its role vis a vis the existing telecommunications infrastructure, a compromise solution was evolved which created a new major telecommunications organization. This new company, which represented the U.S. in the International Telecommunications Satellite Organization (INTELSAT), was called the Communications Satellite Corporation (COMSAT), and was able to provide a variety of services over a single network, including television, telephony, leased lines, telex and high speed data. Another event occurred which impacted the forms of communications transmission available, namely the invention of fiber optic cable technology. Both of these new technologies offered lower costs for telecommunications, and resulted in additional competitors coming into the arena.

A third significant change was the recognition that computers would become increasingly more important in communications as automation was used to lower

002

costs and increase efficiency. IBM's foray into communications through Satellite Business Systems (SBS) created a threat to AT&T and other carriers that future communications growth would be controlled by this giant. It became more and more difficult to define precisely what was a communications service and what constituted a computer service. The FCC instituted a series of "Computer Inquiries" to try to set rules for the development of both services, never quite resolving things.

Computers were only one of a series of new ancillary communications devices impacting users. Answering machines, facsimile machines, and other innovations demonstrated that new rules were needed. While AT&T was not permitted to provide data services over voice lines, it became clear that customers were not observing the rules and it was impossible for AT&T to enforce them itself. Users required more permissive open architecture in their networks as they tried to make all the pieces capable of interoperating with each other. Further, as customers became aware of alternative means of satisfying their communications requirements at lower prices, a number of carriers found this new competition negatively impacting their revenues, as various services started to decline, first telegram, then telex and datel. Slower speed data services became replaced by more cost-effective higher speeds, enabling users to expand their capabilities substantially for small increases in cost. A down-sizing of the industry followed as companies merged to maintain a sufficient volume of business to justify the continuance of services. The end result became a recognition that the carriers must increase the size of their markets, and to do so, they must be able to offer a greater variety of capabilities to users who wanted to integrate their various specialized networks. Customers also wanted to be able to work with one carrier who would have the responsibility to make everything fit together, rather than have to figure it all out for themselves to make it work.

4. THE MOBILE SITUATION

During this evolutionary period for domestic networked systems, similiar changes were taking place in mobile communications. Maritime communications originally started as morse code telegraphy, and high seas telephony was later added. The high seas telephony service was patched into the domestic public switched network and permitted the two systems to work together. On land, a number of private VHF and UHF systems were authorized to operate on specific frequencies, with calls occasionally patched into the PSTN. All of these services were provided on a manual basis. Again, new technologies evolved which created competition for these systems and the carriers providing the services. In 1976, COMSAT launched its MARISAT system which enabled users to obtain automatic service through the domestic PSTN and the satellite system to remote users. On the land side, a new technology known as cellular telephone also permitted mobile users to directly interconnect to the local telephone networks. The same factors causing upheavals in the domestic networks affected the mobile carriers. HF telegraphy service demand dropped, as users saw the superior capabilities and lower cost of satellite technology, and the HF telephone service saw much of the growth in maritime telephony going to satellites. In response, a number of coast stations were closed in order to permit sufficient volumes of traffic through remaining facilities to make them economically viable. On land, cellular radio telephony was a virtual explosion, vastly outstripping even the most optimistic forecasts of demand. Of interest to this change in use of technology was the development of standards for equipment, which permitted widespread service between equipments of a large variety of manufacturers. The greater competition by manufacturers resulted in lower costs of hardware for users, which, in turn, stimulated demand for the services. This whole process is demonstrated very well in the MARISAT/INMARSAT experience, which is a model of how a communications system can be designed to maintain substantial flexibility to meet changing user requirements.

5. THE MARISAT/INMARSAT MODEL

As was the case for many new start-up ventures, the MARISAT system developed by COMSAT started with an uncertain market. The U.S. Navy required an interim satellite communications capability pending the deployment of its future FLEETSAT system. COMSAT management conceived the idea of coupling this service requirement with developing a new market for commercial maritime satellite services. Building three satellites (one as backup in event of a launch failure) to satisfy a two-year, two-ocean service requirement, COMSAT was able to successfully launch and place into orbit all three satellites, thereby expanding the Navy service to cover the globe. Delays in the Navy program, coupled with increasing requirements, extended the period of the Navy lease, thereby enabling COMSAT to more fully develop the commercial services.

At this same time, activity was progressing towards creating a new international satellite system known as the International Maritime Satellite Organization (INMARSAT). When INMARSAT began commer-

cial service in early 1982, the MARISAT system formed the backbone of the INMARSAT space segment with the transition of all three satellites and a user base of over 1000 ships. Again, on a cost-effective basis, the space segment was implemented with leased satellites to provide sparing and greater capacity made available through larger satellites. Because MARISAT, and later INMARSAT, were capable of providing new and improved services similar to that available through land-based networks, a plethora of new mobile services were tested successfully, including 56 kbps data, compressed television, E-mail, packet data and voice broadcast services.

The allocation of L-Band frequencies for mobile communications also created additional opportunities to respond to user demands and serve additional markets, including land-mobile and aeronautical satellite services, all of which are interconnected to both public and private networks. Recognizing the importance of the Department of Defense Global Positioning System (GPS), a differential GPS service was offered, and plans are being made to provide an aeronautical integrity service with the deployment of the third generation satellite system in 1995.

6. CONCLUSIONS

The purpose of this paper was to provide insights into the need for open architecture in developing communications networks in order to permit users the flexibility of obtaining the benefits of new technology through existing systems without having to completely replace their networks. The effects of changes in technology and regulatory policy have had dramatic impact on the communications industry and its structure. With change taking place at an increasing rate of speed, the expectancy of life of any system is shorter, and the certainty of recovering the investment in increasingly more expensive and complex systems is not assured.

ADVANCED MESSAGING IN THE PACIFIC REGION

By Alexander H. Good, President
Mtel International
Jackson, Mississippi

As we move into the age of the global marketplace, mobile communications systems are expanding their scope and evolving to provide valuable new advanced messaging services for local, national and international users. Nowhere are these new and exciting services more needed or evident than in the Pacific Region.

COMMUNICATIONS IN THE YEAR 2000

As we look forward to the Year 2000 and a new millennium, and look back five hundred years to Columbus and the discovery of the New World, it is a fitting time to reflect on the past century and its many changes and accomplishments. Clearly there have been significant geopolitical changes -- the rise and fall of Soviet Communism and its iron curtain, the rebirth of Europe and Japan out of the ashes of world wars, unification and discord in the Middle East, and the quiet but constant rise to economic prominence of the Asia Pacific region. There have also been major technical accomplishments -- the invention of the telephone, the automobile, and the computer; the first men in space and on the moon. Inter-related with, and as a result of, these changes and accomplishments was perhaps the greatest landmark of these last hundred years, and that is the commencement of a new global information age. We stand on the brink of a new era of a world economic community where modern communication technology is serving to unite far flung nations into new alliances and relationships.

The recent war in the Middle East is a clear example that this new age has begun. The eyes of the world became fixed on the Gulf as an alliance of nations banded together to turn back Iraq's aggression into Kuwait. The instant television coverage of the war was the most visible sign of our modern global communications arsenal and it served to provide viewers in all parts of the world with immediate information about the war. But a great deal important communication was also taking place behind the scenes, before, during and after the war. First, diplomats and negotiators urgently communicated with each other around the planet in attempts to find a peaceful resolution to the conflict. Later militaries deployed, gathered intelligence and prepared for battle using space age communication technologies. Finally, the end of the war was announced and troops were sent home; then reconstruction efforts began on a massive scale, involving companies and governments from many interested countries. Through each of these stages, hundreds of people from scores of countries were communicating with each other on a global level to deal with a conflict that affected virtually every corner of the planet.

There are of course many less dramatic examples of this new era, which affect our lives and well-being on a daily basis. One of these is the changing behavior of the world business and financial community. The days of isolation and protectionism are fading as countries are now increasingly becoming dependent on external markets. Even the U.S.A., which used to have adequate domestic economic strength to weather most foreign pressures, now finds itself hugely affected by external factors. A decline in foreign demand for certain U.S. products can adversely affect entire industries. If the price of imports rise, we often cannot find domestic substitutes, so our standard of living is affected. If the U.S. stock market begins to slide, the decline can be fueled by investors who now have the luxury to move their money to another more stable exchange halfway around the world, in an instant.

It is a reflection of our emerging global market that business people travel more than in the past, and more easily. Transportation systems are better; foreign countries are more accommodating. Successful growing businesses expand naturally from their local roots to regional, national or even multinational prominence. Economic trade development activities are at an all time high. Many countries are subtly and not-so-subtly promoting themselves as magnets for foreign investment. Clearly, all these things happening in parallel are conspiring to foster the birth and growth of a truly global marketplace.

It is no surprise that international travel is forecast to grow by at least 10% annually through the coming decade as more companies place increasing emphasis on the international markets which they serve. As business travelers begin to spend more and more time on travel, they will seek out and begin to utilize new communication services which allow them to remain in good communication with their home offices and which allow their clients and customers continuous access to them as they move from city to city, or even country to country.

Business people today must strive to be as efficient as possible in the increasingly mobile and fast paced business world. By using all the tools in the modern business arsenal including the telephone, fax, laptop computer, express mail and others, today's

business people can cope with not always being in the right place at the right time, and can stay productive and informed at all times no matter where they are. The business world is increasingly being defined as the world itself as we move into this age of the global marketplace. It is in this rapidly evolving environment that Mtel is developing the world's first Global Messaging Network, designed to provide constant and instantaneous messaging services on an international basis for the business executive on the move.

CHALLENGES OF THE INTERNATIONAL ARENA

The pursuit of a Global Messaging Network is complicated by certain realities that can affect the way the network manifests itself in different countries around the world. Most important is that telecommunications infrastructures vary so widely in different countries. Another important reality is language and cultural differences between countries. Finally, the dissimilar regulatory environments of different countries make a consistency of service offerings in a coordinated time frame a very difficult objective.

Telecommunications development in the past has typically tracked directly with economic prosperity -- as certain countries grew wealthier, their governments and private sectors invested more money in improving the telecommunications infrastructure. The better infrastructure encouraged business growth, which in turn brought greater prosperity. Increased prosperity brought in its wake higher demand for new value-added services. Thus, the most developed countries enhanced their communications capabilities and achieved additional productivity and wealth due to the efficiency gained through improved communications. There are many specific examples of this fact in the Pacific Region, on both sides of the ocean, including the U.S., Japan, Singapore, Canada, Korea, Hong Kong and Taiwan. Many more countries in the region who appreciate this reality are now in the process of making dramatic improvements to their communications infrastructure including Mexico, Malaysia, Thailand and others.

In recent years, however, telecommunications manufacturers and operators from the most developed countries have turned their attention to foreign markets in an effort to increase their exports. The beneficiaries of this new attention will be the less developed countries who offer vast market frontiers and who, out of necessity, are changing their regulatory environments to encourage investment by foreign companies who have technology. Many of the world's government communications monopolies have been deregulated, privatized and/or corporatized in appropriate ways during the last decade, and the deregulation trend is continuing at a rapid pace. As segments of the communications market are opened up, foreign manufacturers and operators are flocking in to fill the void. The result has been the financing and installation of today's most sophisticated technology in countries that, if left to their own market forces, might not have afforded or justified such systems for many years.

The worldwide development of cellular telephone systems provides a clear example. In an effort to sell more switches, transmitters and phones, the major manufacturers from America, Asia and Europe have launched a worldwide competition to promote the licensing and installation of advanced cellular telephone systems. Telephone companies anxious to increase their global operating presence, including the U.S. regional Bell operating companies, have pushed communications ministries to license valuable radio spectrum as fast as possible. Soon it will be possible to speak on portable cellular phones in rural Indonesia, or the outskirts of Kuala Lumpur, or the airport at Beijing, even though it may not be possible to find a convenient wireline telephone in these same places.

Similar forces have contributed to the proliferation of paging systems around the world, and just as cellular has found surprisingly healthy demand as an alternative to wireline telephones, so too can paging systems be used to satisfy communication needs in lesser developed countries.

THE NEW FACE OF PAGING

Paging is often thought of as an adjunct to the ubiquitous touchtone telephone. Fully automated DTMF input of phone numbers has become the paging product of choice in countries with large pager populations. It is easy, automatic, fast and reliable. In other parts of the world, however, paging may manifest itself in very different ways and become more of a one-way message communication system than simply a "call back alert" system.

Where DTMF touchtone phones are not readily available, callers cannot input pages directly and so human operators provide the interface between callers and the paging system. Since callers dictate messages to the operator, they are inclined to dictate longer, more complete messages rather than simply "call back" phone numbers. This is beneficial as the message recipient will not be obliged to make an immediate call back, which could be problematic given the lower density of public telephones in many countries. Alphanumeric messaging is in fact the product of choice in most of South America, Europe and Asia.

Interestingly, alphanumeric messaging is also enjoying renewed interest from U.S. carriers who see the value of sending complete written messages. Previous problems with message input are being solved today with convenient interconnections to E-Mail and PC software packages. Alphanumeric messaging is very logical for international paging networks because it does not demand an immediate call back -- almost a necessity

when the caller and receiver are separated into disparate timezones.

Another new approach to the pulse/DTMF problem is voice recognition technology, which allows callers to communicate verbally with computers. This technology allows a caller to speak a subscriber identification number or security code into a computer and to give the computer other commands, even when the call is placed from a rotary dial telephone set. Obviously, this approach holds great appeal because it reduces expensive human operator involvement and allows more private, automatic operation.

In parallel with the evolution of paging technology to allow more appropriate message input techniques and more complete messaging capability, the pager is also finding logical marriages with other forms of communication. In addition to its more traditional paging services, other services also being introduced by Mtel include "SkyTalk" Voicemail with paging alert, Fax Mailbox with paging alert, and Electronic Mail with paging alert. While these communication services have been available in less convenient forms for many years, they gain significant additional utility when coupled with the pager notification and portable convenience. Voicemail, Fax and E-mail can be high priority, time-sensitive forms of communication and yet, without notification alert, a slow delivery process can often defeat the real value of these technologies. With the integrated Mtel services, subscribers receive instant notification of the existence of messages, whether they are voice, Fax or E-mail, and can then arrange immediate retrieval and response from any touchtone phone no matter where they are.

Mtel sees the need for, and is actively participating in the development of, integrated multi-function devices such as cellular phone/paging receivers, pager/laptop computer devices, and other light-weight, portable, hybrid devices that will provide convenient communication for the travelling business person. Recently, Mtel and AT&T announced the initiation of a joint proposal to market a "wireless E-mail" capability enabling business people on-the-move to receive electronic mail messages via paging receivers directly into a portable AT&T Safari notebook computer.

MESSAGING OPPORTUNITIES IN THE PACIFIC REGION

With almost half of the world's pagers, over 10 million in service nationwide, local paging is becoming a mature industry in the United States. Local paging is used in the US today by over 3% of the country's population. While local paging will continue to grow throughout the 1990's, the recently launched regional and nationwide systems will grow faster, as paging and messaging services are adopted by a new group of users -- travelling business people. International paging is only in its inception of the U.S. but holds great promise for future growth given the geographic breadth of U.S. activities, both in the private and public sectors.

In Japan, local paging needs are well served by NTT and the new common carriers and local paging is used by an even higher percentage of the population than the U.S. Convenient user-friendly nationwide paging on a single frequency, however, is not today available, nor are any international paging service options. Given the propensity of the Japanese to use paging services and their ever expanding economic activities, they are highly likely to be active consumers of national and international paging networks. Mtel is extremely pleased that it has forged an alliance with NTT to market international messaging services to the Japan market and hopes eventually to link up this critical country as a fully functioning member of Mtel's global network.

While the U.S. and Japan together are home for 75% of the world's pager users, there is vast untapped demand in these countries for new advanced messaging services. With the proliferation of voicemail, E-Mail, Faxmail, cellular phones and laptop computers, many interesting and logical new applications for paging and mobile messaging are presenting themselves. As mobile communications marries itself to computer and messaging, new market niches will be found. It is not at all unrealistic to estimate that eventually 25% or more of the population in the most developed countries will be using mobile messaging in one form or another.

Singapore and Hong Kong with their rarified demographics boast over 10% penetration rates for local paging, so there appears to be little room left for growth of traditional local paging. International paging, however, holds great promise for significant growth. If one takes a trip from these city-state nations, by definition one goes out of the country. Mtel anticipates great demand for its international roaming services in these countries and is exceedingly gratified that both countries are now part of Mtel's global messaging network.

Singapore Telecom shared Mtel's vision for an international messaging capability and agreed in 1990 to purchase a 931.9375 MHz paging system using Mtel's proprietary technology. Singapore's international system was recently launched, establishing the first direct linkages between the North America network and Asia. In Hong Kong, a compatible 931 MHz system also utilizing Mtel's proprietary technology was recently licensed and will be launched in mid-1992. That system will be owned and operated by Sky Telecom Services, Ltd., a joint venture between Mtel, Pacific Link Communications, and Singapore Telecom International.

Taiwan has made remarkable progress in recent years with developing its paging industry. The government monopoly for communications of Taiwan,

the DGT, has installed and marketed high quality systems which now serve over 7% of the Taiwanese public. The DGT believes that Taiwan will eventually eclipse Singapore and Hong Kong and claim the world record for highest paging penetration. Taiwan's great success with local paging bodes well for the country's potential with an international service, especially since Taiwan is constantly increasing its role in the regional and world economic community.

On the other end of the paging industry development scale, Indonesia, Brazil, Philippines, Mexico, India, Pakistan, and China, with their sizable populations, have pager penetration rates well below one half of a percent. Clearly in these populous countries, local paging holds great business potential, especially as infrastructures are modernized and income levels grow. Mtel has become convinced of the viability of paging in undeveloped countries because of our participation in a paging venture in Thailand. Given the relatively low density of telephones and income levels, we did not expect paging products to be taken up rapidly. We were pleasantly surprised when our venture placed over 30,000 units into service in the first three months, and hit the 70,000 mark at the end of the first year of operation. Clearly there can be a great deal of demand for paging services in countries which do not fit our conventional demographic profile.

An exciting but unorthodox way of looking at paging technology in lesser developed countries is as a full communication service that provides an alternative to normal telephone or postal mail communication. Given the low density of telephone lines in many countries, paging service providers must modify their approaches and thinking about system design and operation. Even the very basic concept that paging messages are input to the system via telephone should be reassessed. Walk-in message centers, for example, could be used to allow a broader market for mobile messaging services. In any case, the paging system offers a vital communication capability that can serve those people who might not be able to afford or obtain other alternatives, such as basic phone service, in the near future.

In the Pacific Region, there are still excellent revenue opportunities in the local paging area, especially in countries that have lightly developed paging industries such as Indonesia, Mexico, Brazil, China. In the nationwide and international paging segments, the market is virtually untapped and waits to be developed in all countries.

CONSISTENT COMMUNICATIONS FOR AN INCONSISTENT WORLD

Many of the international opportunities in paging and messaging are the direct result of efforts made by companies like Mtel who have a vision about global communication systems and services. Mtel has been pursuing for several years an active campaign to encourage governments around the world to allocate a standard frequency and to take a standard approach to licensing paging systems, thus allowing the interconnection of a worldwide network. Over the years, governments have carved up their spectrum in very different ways, despite the various efforts to maintain some world standards. Without active international lobbying, countries end up adopting dissimilar standards and approaches for their domestic communications systems, and they develop their communications sectors at very different rates. If not influenced, the result is a chaos of inconsistent systems that precludes any chance of truly international operation.

Mtel has a futuristic vision of worldwide personal communications systems. Eventually, Mtel hopes to achieve a system of interconnected mobile messaging networks on a common frequency which allow a subscriber to effortlessly move to another city or country without the need to obtain a new device or special training.

Founded on a "Follow Me" function, Mtel's system permits a subscriber to maintain continuous international coverage simply by dialing into the system and entering certain simple routing commands. The systems are designed with spectrum efficiency and affordability in mind. If a particular user needs coverage only in Hong Kong, he will be able to restrict his service to that level and pay a lower monthly price. If, however, he needs to extend his coverage for a period of time to Singapore, the network and software can accommodate this. If his work or personal life takes him to Singapore for a time, or perhaps to New York, Honolulu or Toronto, the network can follow him and allow his service to continue regardless of his location. The critical thing is that he never has to change his access number so his colleagues, family, boss or clients can always reach him in the same easy way, whether he is at home or halfway around the world.

Global accessibility is a critical component of Mtel's long-term vision for advanced messaging systems. The two basic reasons behind this are simple -- (1) business people are travelling more frequently and more widely, and (2) the larger the market demand, the larger the number of products and services that can be economically developed and supported.

A global paging network can also serve a non-travelling market by providing distributed message input points and low cost telecommunication links between countries. If a subscriber is programmed into the database of a foreign system, callers from that foreign country could conceivably contact him via their local paging network and enjoy all the associated advantages. If VoiceMail, E-mail, Faxmail and other value-added enhancements are linked to the basic paging functions, the power of this communication capability increases dramatically. A caller from Paris could conceivably

deposit a voicemail E-mail message in France for a person in Hong Kong for less than the cost of an direct dial telephone call. Once a global network is widely deployed, it is very possible that this non-travelling market will overshadow the travelling segment in size and traffic volume.

Mtel's vision for a global capability is shared by pioneers in other areas of mobile communication. Cellular carriers are also working to develop compatible systems based on common frequency assignments and computer technology. In addition, other futuristic systems are on the drawing board, such as Motorola's "Iridium" satellite-based cellular phone system which will allow worldwide operation with a single phone set and phone number. As all these various approaches come to fruition, true global networks will result that will allow business travelers to move from country to country while maintaining constant communication.

There are many skeptics who do not yet acknowledge the immense potential of global messaging networks. There were equal numbers of skeptics in the early 1980s who predicted, incorrectly, that nationwide paging would not materialize into a significant business. Clearly paging and messaging services hold an important place in modern communications. There are many hurdles to be overcome in implementing global messaging networks, including regulatory processes, competitive threats and infrastructure limitations, but the potential is too compelling not to aggressively pursue and develop these systems on a truly global level.

These global systems will offer new and powerful mobile communication services to enhance the productivity of business travelers and others, and facilitate the challenging job of conducting business in global market. Through its direct activities and strategic alliances, product development activities and local joint venture partnerships, Mtel has taken a leadership position in the area of international messaging. Mtel is proud to announce the first operational international messaging network linking the United States, Canada, Singapore, Mexico, and soon Hong Kong and other countries. Through its efforts on many fronts, Mtel is striving to expand the frontiers of mobile communication and to develop appropriate tools for the new global information age.

TOWARDS THE NEW AGE OF MOBILE COMMUNICATIONS
--- NEC's MOBILE COMMUNICATIONS PLATFORM ---

Tomiaki Mizukami, Minoru Tanaka, and Yuji Kitahara
NEC Corporation
4035, Ikebe-cho, Midori-ku, Yokohama, 226, Japan

1. ABSTRACT

The concept of the platform for mobile communications network is the one of providing flexible coverage to offer the optimum in personal communications in the 21st century.

2. GENERAL DESCRIPTION

In the communications area, the best optimized infrastructure are being considered in each country for the coming of information society in the 21st century. On the other hand, world wide standardization will also be needed for users' convenience in a borderless age. Under above circumstance, communications itself will be migrated from "machine's communication" to "personal communications" and personal communications will be the major infrastructure which support and substitute the fixed communication networks. This paper will discuss NEC's Mobile Communication Platform (MCP) for the future personal communications based on the area that comprises not only of systems but also terminals.

3. CONCEPT FOR MCP

The objects of personal communications are to communicate anywhere, anytime with anyone. Also, easy operation and user-friendly interface are most important. Many different mobile communication are now operating in the world and many of the users (including operators) may feel inconvenience because of the terminal's incompatibilities and coexistence of many different and independent communication services in a country. For example, users feel frustrated when using mobile communications services by cellular, cordless and satellite systems because of the different systems and terminals. In order to solve such drawbacks, NEC proposes the MCP based on;

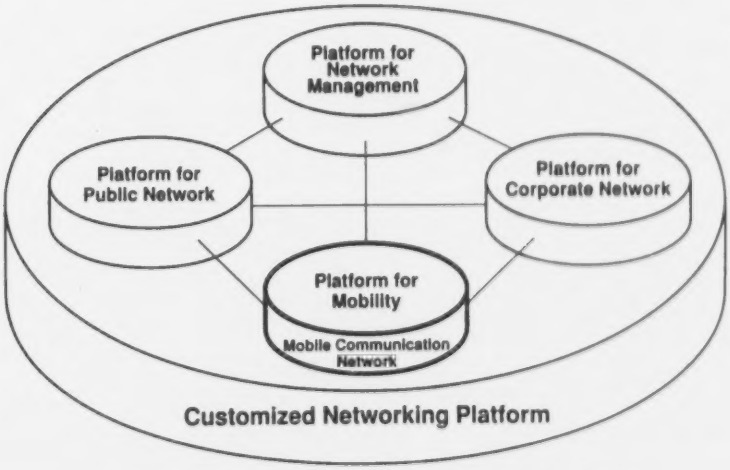

Fig.1 Structure of NEC Customized Networking Platform (CNP)

1) Digitalization technology
2) Effective use of frequency spectrum technology
3) Mobile communications network technology
4) Terminals technology

and NEC's MCP provides the one system integrated different mobile systems.

4. STRUCTURE OF MCP

As shown in Fig.1, the MCP is the one network element on the CNP (Customized Networking Platform) that is a part of NEC's total concept, Computers and Communications (C&C).

The MCP includes not only the radio but the switching, transmission, and network management systems in its network and also interface with other network elements of CNP such as public, management and corporate networks platform. Through this interface, the MCP provides the variable and attractive mobile communication services such as ISDN, video etc.

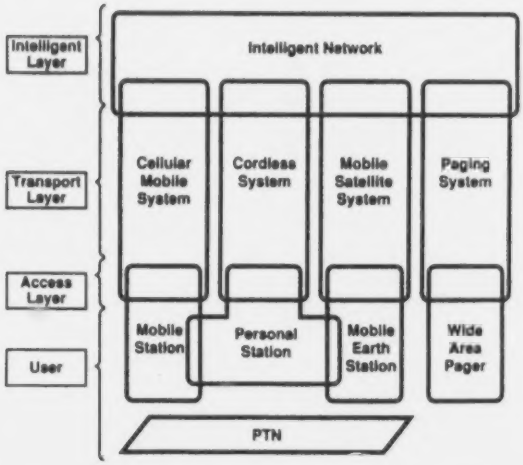

Fig.2 Structure of Mobile Communications Platform

Fig.2 shows the system structure of MCP that is a part of CNP. The user can get the communication services by one common terminal for the cellular, cordless and satellite mobile systems by using a personal identification number and a system approach number.

The NEC Mobile Communications Platform consists of the following four subsystems:

Cellular Mobile System: Provides communication services to high-speed mobile stations (MS), and to personal stations (PS) via MS.

Cordless System: Provides communication services to PS terminals for public, office and home use.

Mobile Satellite System: Provides communication services to low-traffic density mobile earth stations (MES), satellite terminals and to cordless system PS terminals via MES terminals.

Paging System: Provides call/message services to wide-area pagers (WP).

5. BASE STATION FOR MCP

For increasing the system capacity up to the few million within the limited frequency bandwidth, a micro-cell, or pico-cell with a radius of 100 to 500m will be needed. This means that a huge number of the base station should be installed and the investment cost will be increased. To improve the system cost, small, light-weight, low power consumption and low cost base station must be developed.

Fig.3 shows the trend of the relative volume of the base station from '70 to the 21st century. By using VLSI, the base station in the 21st century will be downsized to 1/100 compared with the 70's.

But in addition to the downsizing the base station, the total volume including the approach link and installation materials should be considered. An example of the future integrated MCP base station is shown in Photo 1.

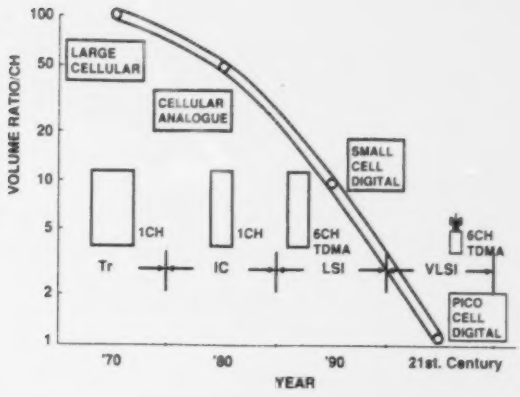

Fig.3 Volume Trend of The Mobile Cellular Base Station

Photo 1 Integrated Mobile Cellular Base Station for MCP

6. MOBILE TERMINALS

The attractive features for users about mobile terminals are their small size, light weight, long battery life and user friendly interface. For decreasing the size and weight, semiconductor techniques such as VLSI and battery technique will be greatly required. Fig. 4 shows the history of downsizing the mobile terminal by the semiconductor's advancement.

Photo 2 shows the latest, small hand held portable analogue telephone terminals. And in the future, by the MCP concept, pocketable and multimedia mobile terminals integrating the voice, data and video services will be developed.

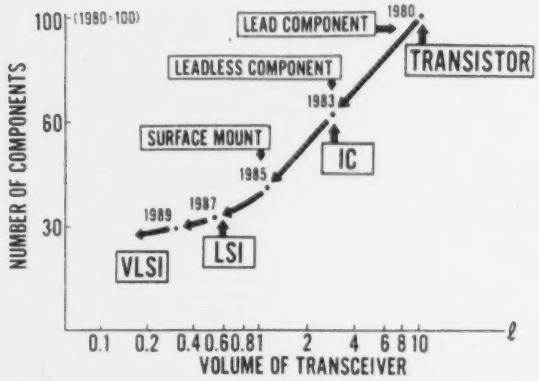

Fig.4 Volume Trend of The Mobile Hand Held Telephone Terminal

812

7. CONCLUSION

NEC's MCP aims to realize the ideal personal communications in the future. And the MCP can be connected to CNP that is the total solution that NEC's Computer and Communication (C&C) concept is striving to provide.

The user can use mobile communication services anytime, anywhere, with anybody, overriding obstacles caused by incompatibilities and system difference.

REQUIREMENTS FOR WIRELESS LOCAL AREA NETWORKS

MIL OVAN
WORLDWIDE MARKETING MANAGER
MOTOROLA, INC.
ARLINGTON HEIGHTS, IL

ABSTRACT

Wireless In-building Networks (WIN) represent the next major communications frontier for radio applications. The author has performed extensive primary market research to determine the communications needs for the 1990s, focusing on this new market segment. This paper highlights the results from over 1000 corporate and government entities surveyed through different marketing research techniques, with particular emphasis on Local Area Networks. Discussions include: the personal computer trend and local area network growth; the problems with cabling, particularly associated with business moves, adds, or changes; cost effectiveness of wireless LANs; requirements of a wireless local area network for acceptance by the users; the environment best suited for wireless LANs, and specific product requirements.

THE WIRELESS IN-BUILDING VISION

To date, the evolution of wireless communications has been exemplified by the dramatic growth in cellular communications. Cellular has enabled customers to transcend the constraints of fixed telephony in communicating outside of buildings with portable, and now personal, communications devices.

There has been significant interest and publicity regarding wireless in-building communications lately, both for data and voice. Throughout the 1980s, we have seen the development of a significant range of in-building business communications problems that have been caused by changes in the technological, business, and regulatory environments. Because of these developments, buyers of telecommunications and data communications systems increasingly are having to face significant time, cost, and logistical problems associated with the installation, movement, and management of computing and communications equipment in dynamic office environments.

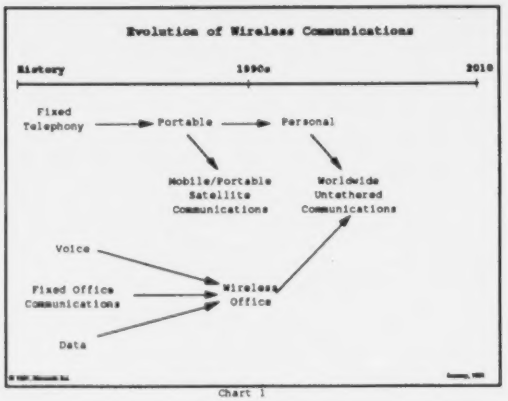

Chart 1

Over the next 20 years, society will witness a significant "wireless evolution" in both personal and professional communications, and change the way we conduct our lives at home, on the road, and at work (See Chart 1). New forms of wireless communications will free us from the "bonds" of wire that today restrict our movements or interaction.

MARKET RESEARCH

Beginning in the mid-late 1980s, a systematic evaluation of the technological and environmental attributes necessary to anticipate and define wireless in-building communications was undertaken. This included a comprehensive marketing needs assessment and research program.

The overriding objective was to anticipate and identify customer needs and trends; that is, "What are the specific needs of various customer groups, and what type of product attributes will satisfy their needs?"

To determine answers to these and a whole host of other questions, a multi-phased marketing research program was conducted. The overall aim of the program was to anticipate and ascertain the customer need, where this need existed currently, what are the market and customer environmental characteristics, and what product characteristics would be needed to provide an optimal wireless solution.

The remainder of this paper describes a higher level overview of the results from these market research phases. This includes an overview of market needs, the problems/difficulties with current cabling methods, and a description of market requirements.

LAN MARKET FACTORS

Personal Computer Explosion

The move from mainframe and central information processing of the 1960s and 1970s provided an opportunity for mini-computers to enter the market. The mini-computer enabled greater computer and applications access by employees.

Throughout the 1980s, the move to more intelligent desktop devices like personal computers were just that--personal. Organizations, in an effort to empower the worker, provided all types of applications, software and hardware to the worker. The decremental costs of technology facilitated the distribution of personal computers. More importantly, projections state that business personal computer growth will continue its aggressive pace (See Chart 2).

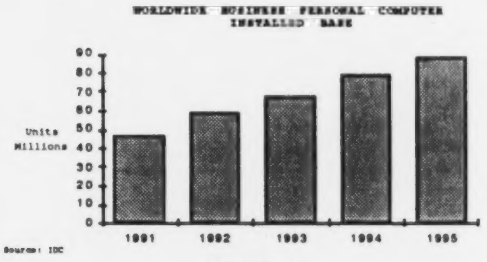

Chart 2

However, the growth of decentralized storage and computing created yet another problem--work groups needed to share information. However, much of this information resided in individual hard disks.

Furthermore, despite the declining costs of personal computers and associated technology, it was and still is considerably expensive to "fully load" the workforce with all of the applications it needs. The ability to share applications became desirable. It was these two trends which highlighted the need for Local Area Networks (LANs).

Information and Resource Sharing

The success of local area network computing was predictable. It started with the basic tenet of sharing resources and/or information. The need to amortize and justify the purchase of expensive resources, such as printers and storage, was an obvious factor which supported LAN growth.

The need for knowledge workers to exchange data was and is imperative. Furthermore, the ability to share applications supported the growth of network computing.

LAN Growth

The sales success of LANs throughout the 1980s has been phenomenal. However, the projected growth throughout the 1990s is equally as impressive (See Chart 3). This can be attributed to not only new installations of LANs, but also to the physical and logical segmentation of LANs as traffic and throughput degradations are observed.

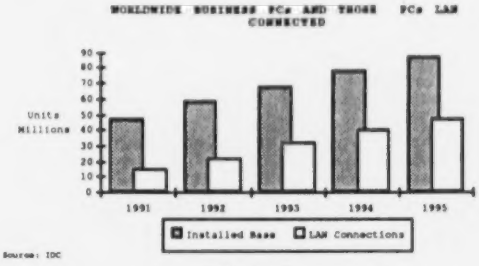

CHART 3

Moves/Adds/Changes And Increasing Mobility

The world economies will continue to develop interdependencies and likewise, global competition. The increasing competitive environment will demand greater worker mobility, changing assignments and reassignments, changing work groups, and mission mobility.

The demand to have information how we want it, when we want it, and where we want it, will be a strategic and competitive weapon. The need to improve efficiency and the growing need for information will accelerate the adoption of wireless communications.

Today's wired network, for all its great strides, remains very restrictive. The cost to deploy and redeploy personnel and work groups is time consuming and expensive. Cabling in today's environment inhibits the ability to attain efficiency and competitive advantages. The next section will highlight some of the author's market research findings.

CABLING PROBLEMS

As each phase of market investigation was conducted, several problems with today's wired networks were uncovered. Whether twisted pair, coax or fiber optic cable, hard wiring for telecommunications and data communications systems within a

building environment is expensive and troublesome to install, maintain, and especially, change. Beneath today's increasingly dense office electronic environment lies a tangled, confusing, virtually unmanageable maze of wiring.

What appeared to be the most consistent response in the focus group research was how quickly the respondents stated the many problems they have with wiring. And, among the majority of respondents, the most favorable solution to this problem was to free themselves of all wiring. The first choice solution would be a wireless system, minimizing the time and effort of implementing a move, add or change.

Moves/Adds/Changes: Cost and Frequency

A major portion of the cost of LANs is the cost of interconnecting them, which experts acknowledge can sometimes exceed the cost of computer hardware and software. Labor and material costs for wiring are almost always significant, and can reach $1000 per node just for copper wire. Coax and optical fiber costs, not surprisingly, are considerably higher.

The news, however, gets even worse when it comes to maintenance. A recent study by the Frost and Sullivan[1] group indicates that LAN moves, adds and changes (MACs) is the third largest cost component of LAN operation. MACs account for almost $2 billion of a $12.2 billion annual LAN maintenance market. Additionally, this $2 billion does not even include the original cost to install cable.

Estimates of the cost to rewire a node range from $200 to $1000 per change. In fact, a survey by KPMG Peat Marwick[2] recently stated that the average relocation cost for just rewiring a LAN node averages $300 per node. But those are just the direct costs; the time to effect the wired change is a significant problem as well. Moves, for example, often take weeks or longer to coordinate in addition to the time to actually make the physical wiring change.

Most of the research respondents were asked what proportion of their company's staff was involved in some kind of a move involving wiring or rewiring. The majority of the respondents, almost 80%, had some type of relocation or addition of personnel over the last year surveyed. And, the respondents' frequency of moves ranged from as few as 20% per year up to as much as 200% annually.

These statistics are corroborated in the KPMG Peat Marwick study, where it is indicated that the average company moves its employees approximately 50% annually. Telecommunications consultant Richard Kuehn states that data terminals are moved as often as 1.5 to 3 times per year. The problems of the actual hard relocation costs, however, are just the beginning. Soft, or hidden costs, further exacerbate the cabling dilemma.

Hidden Costs

Significant problems arise when moves or changes are implemented. There is always the disruption of the workers involved in the move or change, not to mention the loss in productivity.

The problems, however, become much more involved when dealing with whole departments and more complex user equipment. In fact, surveyed firms responded that a relocation (60% of the time) involves the movement of an entire department.

The toll of wait time and down time on productivity varies greatly and is difficult to quantify, but certainly is significant and costly. And in today's increasingly mobile working environment, it is likely to grow. The situation is exacerbated by relocations and additions which require reconstructions, thereby, continuing to add to the effective cost of a move, add, or change.

Another major hidden cost area surfaced regarding the age and complexity of a building. The majority of high-rise office space in large metropolitan areas presents significant problems and expense for tenants trying to install, add or move network wiring.

Buildings more than 30 or 40 years old, with designs and construction that did not consider today's electronic office, poorly accommodate communications wiring. If asbestos insulation exists in the building, as it does even in many pre-health-safety regulated buildings, rewiring costs can take on huge proportions.

The coordination of personnel and the moving of one group out to prepare for the new group moving-in is a very costly and labor intensive ordeal. In some cases, wiring had to be installed, or different cabling may have been needed to accommodate new or different types of users' equipment.

---

[2] KPMG Peat Marwick Study, January 1991

Cable Is Not Business Friendly

Although office planners, building managers, and network operators are well aware of the problems with wire, the limitations and huge costs of wire haven't generated focused attention outside of this community. The general business world seems to accept wire as inevitable. Perhaps that's because there have been no real alternatives.

Yet, as computing and telecommunications power continues to proliferate and becomes more widely distributed to the "knowledge worker", the problem will increase. Easy, quick, efficient movement of "people assets" within the working environment is also increasingly being recognized as essential to a business' productivity and competitiveness. Wiring severely inhibits that movement.

The research indicated a need for a flexible, compatible, cost effective, yet high-performance wireless alternative to extend and complement, if not replace, the capabilities of wire, cable and fiber for in-building communications networks. More specifically, it is the greater convenience and flexibility that users need. In fact, the aggregate need for flexibility and convenience was found to be two times more beneficial than that of the perceived benefit for cost savings.

When research respondents were asked how they could improve upon their experiences when implementing a move, add or change, many solutions were offered. These solutions ranged from having more compatibility among different vendors' equipment, to providing a better way to organize all the different cabling.

Structured Distribution Systems

A number of firms in the research study had deployed Structured Distribution Systems (SDS). An SDS is a topology which advocates cabling saturation of a desired environment to accommodate all potential personnel movements and reconstructions within that office. SDS requires firms to invest large sums of capital initially on the assumption of not knowing how many telecommunications devices may be employed or where the devices are to be located. Consequently, Structured Distribution Systems usually plan for worst case conditions, meaning that some or much of wiring systems capability may never be utilized.

However, many firms which utilize an SDS also expressed those problems which stress their SDS investment. Some of the most frequently mentioned problems include:

- High equipment addition/relocations, exceeding 40% annually
- Expansion and contraction of their workforce
- Changing technology and business support
- Continued investment and vigilance to maintaining the SDS and its intrinsic advantage
- Continued departmental LAN growth requirements

In short, the latter group of SDS respondents provided some notable requirements for a wireless system. They indicated a wireless system must:

- Extend the capabilities of their SDS system
- Facilitate the inherent advantages of the SDS
- Offer enhanced flexibility to non-serviced SDS portions of their building or occupancy.

The above points indicate that even in SDS environments, there is an opportunity to deploy wireless devices. Wiring--the expense, time, and inflexibility of installing, moving and changing--limits the way companies can productively use networks.

To stay productive, these LANs have to move and change with the workforce they support. Therefore, a wireless offering must be a complementary solution for buildings with an SDS, in bringing wireless flexibility and extensibility to today's networks.

USER REQUIREMENTS: ENVIRONMENT

Several notable conclusions were derived from the marketing research:

Office Friendly

First, research suggests that over 70% of LAN node installations were resident in an office environment (as opposed to factories and warehouses). Therefore, as an office oriented offering, a wireless system would have to be, by definition, office friendly.

A traditional office is composed of hard offices with opening and closing doors, furniture and personnel movement, cubicles, conference rooms, and walls of varying thickness and

81

substance. Therefore, a wireless system must continually adapt to different and changing conditions, and office layouts.

Optimized Service Area

The second wireless in-building need expressed by the office market is the manageability and reuse of any potential system. Unlike the signal propagation characteristics of many lower frequency radio products, LAN administrators desired the ability to control, or more aptly, contain, the coverage of a potential wireless system. The reasons were twofold:

- LAN managers wanted the ability to add different services to a new group of users. In fact, these new users may very well be physically adjacent to another system, wireless or wired.
- These same managers wanted the flexibility to connect a new or existing user group to either a backbone or to create a stand alone LAN.

LAN Workgroup Sizes

Respondents were asked as to where a wireless offering might be first installed. The market research indicated that approximately 70% of the installations would contain less than 30 users (See Chart 4). Furthermore, the average LAN appeared to be in the 12-15 node range. This is further corroborated by the KPMG Peat Marwick study which found that the average LAN size is about 15 users per LAN.

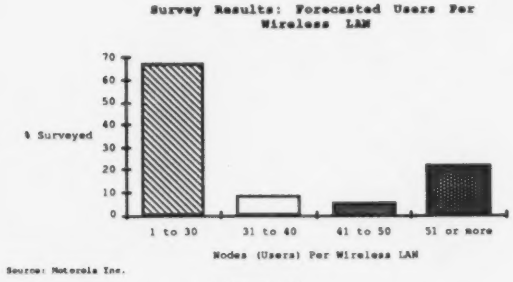

Chart 4

Furthermore, there must be an inherent flexibility to grow the wireless service area. That ability, to either incrementally add systems whether on the wired backbone or in a stand alone wireless configuration, must accommodate scalability within an organization.

It is interesting to note that these figures are consistent with good LAN administration practices for purposes of maintaining high throughput and fault isolation. As LANs become larger and traffic more intensive, there is a natural inclination to begin segmenting LANs into more logical and defined user areas/groups.

Coverage Area

To satisfy the majority of requirements, it has been determined that approximately 70% of LANs would be deployed in areas less than 5000 sq. ft. (See Chart 5).

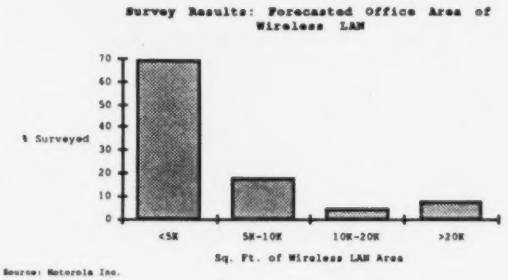

Chart 5

This determination must take into consideration the fairly dense environment, made up of cubicles and apportioned hallway space. The market investigations indicated that a wireless offering must accommodate, at the least, 150 sq. ft. per user. This is equivalent to 32 users/system in a 5,000 sq. ft. area.

PRODUCT REQUIREMENTS: END USER REACTION

Transparency, Compatibility, and Performance

To justify the investment in a wireless system to end-users, a wireless offering would have to provide reliable performance, as well as be practical and cost effective. The market research indicated that the ideal system should be:

- Easy both to install and move, preferably by the user.
- Able to coexist with both existing wire and cable, as well as with future optical fiber.
- Easy to operate, virtually transparent to the user.
- Almost universally applicable, suitable to replace any LAN cable or wire, in any office environment.
- Powerful, performing at multi-megabit per-second speeds.

- Secure, absolutely reliable, and cost effective.

A wireless system is a "media replacement" and therefore must be totally transparent. If the customer is to enjoy the attributes of wireless, the respondents indicated that the wireless implementation must not require the user to change the way he operates or interfaces with his personal computer.

Also, a wireless offering must provide true compatibility. The wireless connection must be compatible with standards-based components such as operating systems and applications, LAN cards and other devices, as well as LAN wire that is already in place.

Security and Reliability

The market mandates that a wireless product offering be absolutely secure and reliable. Security was a requirement across several dimensions. To provide sufficient data security, a wireless system should first prevent the effective capture of data by a receiver outside of the wireless system, and second, prevent capture of the data by unauthorized wireless hardware within the system. A wireless product must be secure from eavesdropping, either accidental or intentional.

Reliability was another important attribute. Users require absolute reliability. That is, users wanted a guaranteed packet delivery from the entry/exit wireline points--and they wanted it at least as error free as their current cabled environment.

Cost Effective

Finally, most businesses will place any capital or expense under rigorous financial analysis. As such, the acceptance of a new technology/application must pass the payback hurdle for that business. Therefore, demonstrable payback justification is needed to facilitate an organization's evaluation of any potential wireless offering.

TECHNOLOGY ALTERNATIVES IN MEETING CUSTOMER REQUIREMENTS

IR and Spread Spectrum Technologies Lack Performance

Developing the ideal system, obviously, is not a trivial problem to solve, and is the reason why a perfect system hadn't appeared on the market prior to 1991. There are three basic technologies which characterize the wireless LANs currently available. Several wireless network products are based on two of the three wireless LAN technologies: either infra-red or spread spectrum. But each of these two technologies suffers from limited performance and operational problems inherent to the technologies on which they're based.

Infrared (IR) systems use a part of the electromagnetic spectrum just below visible light as a transmission medium. IR, being light, travels in a straight, or line-of-sight path. It is blocked by opaque objects and reflects well only off hard, mirror-like surfaces. This factor stands as a serious obstacle to IR systems for applications other than in open working environments.

A more promising candidate might be one of several systems operating just below 900 MHz, at the upper end of the UHF band used by television, FM radio and cellular telephones. Because of the crowded, low availability of bandwidth in this frequency range, these systems use spread-spectrum technology. This technology, developed by the U.S. military, uses a combination of several small, narrow bands within a general region of this band as carrier frequencies.

Although this technology helps to address important interference and security considerations, it can't solve the fundamental problem of available bandwidth. (In radio transmission, the wider the bandwidth or available frequencies on which to encode data, the higher the achievable total data rate.) Even with multiple frequencies, the total bandwidth available to spread-spectrum systems assigned by the FCC is inadequate to support more than about 2 Mbps. Simply put, this area of the RF spectrum is already taken up and accounted for by other uses.

Another important issue in this UHF environment is that RF energy at these frequencies tends to propagate through and around obstacles, reaching beyond the confines of the network that it is serving. That property makes this RF band suitable for receiving commercial broadcast signals from distant stations through the walls of buildings to receivers inside. It also makes it suitable for mobile cellular telephones. But it can't be contained within the confines of the microcell described earlier. And that limits spectrum reuse and overall network capacity requirements absolutely essential in a viable wireless network communications system.

813

Current UHF spread spectrum wireless in-building communications systems, then, suffer from critical bandwidth and spectrum reuse shortcomings that seem likely to prevent them from expanding beyond limited applications.

The 18 to 19 GHz Radio Band: An Ideal Choice for Wireless In-Building Microcellular Networks

The 18 GHz region of the electromagnetic spectrum, above the kilohertz and megahertz radio bands, yet below the extremely high frequencies of the infrared band, offers two very compelling advantages. Specifically, the 18 to 19GHz portion of this band fulfills the key requirements of spectrum reuse and bandwidth availability that eliminates most other frequency choices from serious consideration.

Propagation Properties Right for Both Microcell Coverage and Confinement

The first major advantage of the 18 GHz band is its excellent propagation characteristics for a microcellular network. Indeed, the behavior and properties of these higher frequencies that are disadvantages for traditional long-range broadcast applications become critical advantages for wireless in-building network applications. Propagation characteristics of 18 GHz radio waves make them well-suited to diffuse thoroughly through a network microcell using a minimum transmitted power, yet remain confined so that the same frequencies can be reused by another system within as little as 120 feet or so, or on the other side of a dense, continuous barrier such as a cement floor. Typical microcells might encompass, for example, a level or floor, or portions of a floor, in a standard office building.

As one might expect, 18 GHz radio waves exhibit a blend of the characteristics of both IR light above them, and UHF frequencies below them. For example, like light, 18 GHz waves are blocked and reflected by large structures such as concrete and steel. The 18 GHz waves reflecting back and forth in an area defined by concrete floors, ceilings, and walls, result in thorough radio coverage. The 18 GHz signals also refract like light, penetrating tiny holes and cracks such as closed doors to diffuse and spread through the space beyond. What little radio signal that might escape the microcell would be rapidly dissipated.

On the other hand, like radio and unlike light, 18 GHz signals still can pass through less dense materials such as drywall and interior office separators and, combined with their reflectivity, are not subject to "line-of-sight" limitations. They can also be modulated to carry information just as traditional lower frequency radio signals are.

Also, unlike lower frequency radio, 18 GHz radio is of a high enough frequency that not only office equipment, but even high energy factory equipment and processes don't interfere with it. Likewise, with its high frequency and low required transmitted power, the 18 GHz signals themselves from such a system would not interfere with other electronic systems or equipment.

And, finally, since antenna size and design are largely a function of wavelength, which decreases as frequency increases, the antennas for the 16-mm wavelengths of an 18 GHz radio system would be relatively small and compact.

Plenty Of Bandwidth In An Otherwise Crowded Spectrum

The second major advantage of 18 GHz radio is its available bandwidth. Few other areas of the electromagnetic spectrum are as interference-free, clear and available as this band, certainly not the VHF and UHF bands, which must accommodate television, FM radio, cellular telephone, baby monitors and more.

The reason for this clear band is largely that these higher frequencies have been difficult to work with. The particular technical properties of 18 GHz frequencies and the expense, size, and complexity of the equipment to use them, have prevented them from being an attractive option for many commercial applications. As a result, the military has been the primary developer and user of the 15- to 300-GHz band, and the few commercial uses that have emerged (weather, aircraft and police radar, point-to-point telecom transmission, etc.) use expensive technology pioneered by military-funded research.

For any wireless in-building communications technology to be a legitimate complement to wire, data speeds must be in the multi-megabit per-second range. Achieving these speeds over an in-building radio system, however, had never been done until Motorola recently developed the Altair (R) wireless Ethernet network. Such an application required the creation of new, improved performance data handling and signal processing hardware and software, as well as a radio antenna system that could transmit and capture these data speeds

on 18 GHz frequencies in an in-building environment.

SUMMARY

The numerous problems with wiring will become even more acute in the office of the 1990s. This environment will be characterized by:

- The proliferation of decentralized computing resources.
- Increased number of telephones and personal computers as an outgrowth of a country's economic shift toward service industries.

As the penetration of personal computers nears a one-to-one relationship with phones in the office workplace, the limitations of separate voice and data networks will become even more evident. If these problems are not addressed, an organization's flexibility in redeploying "people assets" and ultimately competitiveness will be seriously hindered.

The time it takes to move/add/change equipment and reconfigure communications wires will be the limiting factor in rapidly reorganizing workgroups and responding to new assignments. Wireless LANs will become an attractive solution in the office of the 1990s, interconnecting personal computers and offering data communications capabilities without the need for elaborate cabling methodologies.

The obvious and inherent flexibility offered by wireless LANs is the obvious primary benefit. However, the ability to retrieve that investment, never retrievable until now, clearly presents a significant economical benefit.

21ST CENTURY SATELLITE OPTIONS FOR THE ASIA-PACIFIC: A COOPERATIVE U.S.-JAPANESE STUDY

Joseph N. Pelton and Takashi Iida
University of Colorado at Boulder
Interdisciplinary Telecommunications Program
Engineering Center OT 2-41
Campus Box 530
Boulder, CO 80309-0530

ABSTRACT

A year long study carried out at the University of Colorado has identified a range of new satellite system options to aid the Asia-Pacific region. These studies, supported by grants from NASA, propose a range of exciting new satellite projects for the Asia-Pacific region.These projects include: (a) A series of lightsat projects to aid education, health, weather alert, rescue operations and telecommunications among Asia-Pacific island countries. (b) A joint U.S.-Japanese operational prototypes satellite that could operate at multi-gigabit/sec speed. (The next step beyond ACTS and ETS-VI). (c) New ways to use GPS packages on low orbit satellites in the Asia-Pacific Region to monitor global warming. (d) New developments in USAT (Ultra Small Aperture Terminal) technology to aid rural and remote services, and (e) Conceptual studies for 21st century satellite systems that have high performance and reliability with minimum transmission delay and easy interconnection into terrestrial systems. The results of these "unofficial" studies will nevertheless be presented to the United States' National Aeronautics and Space Administration (NASA), the Japanese Ministry of Posts and Telecommunications and its National Space Development Agency (NASDA), and the U.S.-Japan Committee to determine their possible feasibility for implementation.

1. INTRODUCTION

The Asia-Pacific region is today at the core of the world economy and in many ways the hallmark of our global future. It is difficult to define the region in a way that is universally accepted. This is because the region has so many subregional elements with many of these at different levels of economic, social and cultural development. The Pacific Rim countries (**See Table I**), now include some 30 nations and are dramatically different in culture, geographic size and economic product from the small Pacific island countries. Although these island countries (**See Table 2**) also number nearly thirty, their population and economic size are two orders of magnitude less. The difference do not end here. The Asian countries are quite different from those of the Western Hemisphere and so forth. Certain facts, however, stand out. The North America countries of the U.S., Canada and Mexico on one side of the Pacific and Japan on the other are the key economic drivers of the region and to some extent the entire world. Japan and her newly industrialized neighbors on the Asian continent serve as economic magnets. These Asian countries pull a great amount of economic trade to their side of the Pacific. Conversely the U.S. and her immediate neighbors on the opposite shore of the Pacific create an opposite attraction. It is thus not an exaggeration to suggest that Japan and the U.S. are the economic motors that drive the vast and rapidly growing Asia-Pacific region and that the key elements of this economic growth are high technology, improved, high capacity communications networks, and expanding trade.

Certainly, the key machinery that makes this vast economic region a reality is not fleets of planes, or ships, or stock markets, or banks, but rather the ever increasing information and telecommunications systems that enables and empowers all these services and more. The contention of this study is that the communications systems of the region is the core element of the Asia-Pacific region as we know it today. In short the Asia-Pacific region as an economic, social and cultural presence would not continue to exist without these electronic systems and their ongoing development and growth. While advanced telecommunications systems are clearly important to other regions such as Europe, the great differences in time and place and culture make electronic communications and information technology especially crucial to the Pacific region.

COUNTRIES WITH TERRITORIES
IN THE ASIA-PACIFIC REGION

FRANCE
UNITED KINGDOM

In this study the Asia-Pacific region is defined as covering the "entire" Pacific Rim and all island countries protectorates as well. Although the full scale study undertaken under NASA Grant (NAGW-1105) examines a much broader range of issues, this paper focuses on specific potential satellite projects that might enhance Asia-Pacific cooperation in the five following areas:

(a) Lightsat projects to aid education, health,weather alert, rescue operations and telecommunications among Asia-Pacific island countries.

(b) A joint U.S.-Japanese operational prototypes satellite that could operate a multi-gigabit/sec speed.

(c) New ways to use GPS packages on low orbit satellites in the Asia-Pacific region to monitor global warming.

(d) New developments in USAT (Ultra Small Aperture Terminal) technology to aid rural and remote services.

(e) Conceptual studies for 21st century satellite systems that have high performance and reliability with minimum transmission delay and easy interconnection into terrestrial systems.

Ultimately the purpose of this study is to examine how the development of new telecommunications technology and innovative new patterns of cooperation within the Asia-Pacific region can contribute to the overall economic, social and political development of the region and perhaps ultimately the entire world. Although the scope of this study is the entire region it clearly gives special focus to U.S.-Japanese cooperation and liaison.

2. LIGHTSAT SYSTEM CONCEPTS FOR ASIA-PACIFIC REGION

2.1 The Appropriate Role for Lighsats

The attractiveness of small, inexpensive satellite communication system for the Asia-Pacific region has been recognized in U.S., Japanese, and other design studies for some time. This is not to say that established satellite systems with advanced high capacity satellites such as the INTELSAT VA, VI, and VII's will not continue in the future to provide the bulk of satellite services. It only suggests that certain niche services especially for rural and remote satellite services and for non-commercial applications like health and education could be met by lightsats. Thus in parallel with the development of large satellite systems, there has been intensive new research and development with regard to light satellites. Small satellite systems are being considered for many different types of purposes, and the payload of these various lightsats range from several kg to 100 kg, with others as much as 300 kgs or more for some specific missions. The missions of such small satellites include communications, navigation, earth observations and engineering test. Lightsats are certainly not a panacea. There are severe limitation in both mass and available power. Clearly, only rather limited missions can be effectively taken aboard small satellites.

The are nonetheless some key reasons why the small satellite has been highlighted recently as an important new option. These include advancements in micro-electronics development, ring gyro laser orientation and positioning, low costs for microsat launch services, fast turnaround time, low total project cost, multiple discrete satellites which can exactly match satellite capacity to traffic demand, and even the psychological reason of having one's "own" satellite[1].

The small satellite can be very attractive for the developing country especially in terms of its low cost. The low cost of the lightsat does not necessarily mean low cost communication per channel but it does mean low total project cost. To date many commercial satellite communications systems have been proposed, particularly with regard to mobile satellite services. Some envision continuous voice service while others would use store and forward data services. Some would use only one satellite such as the initial Satellife Project and some would deploy a constellation of as many as 77 satellites. Some would use low-orbit circular polar configurations and some would be geosynchronous.[2]

Thus, it is clear that there are a great many viewpoints concerning the small communications satellite. Lightsats can thus be considered to be low circular, medium elliptical, or geosynchronous in orbit, range from 5 to 500 kilograms, and be for commercial or social service purposes and can provide one or more of the above noted services although communications is still the most likely application. The small satellite system for the Asia-Pacific region reported upon here is only one of the concepts examined in the larger NASA study. It was selected from among the other concepts because it seemed quite viable for sequential implementation within the region starting with the Federated States of Micronesia (FSM). It can be accomplished at medium to low cost and with reasonable speed of implementation. In short it seems the one most likely to be recommended for a Joint U.S.-Japan Cooperation project.

TABLE 3: LIGHTSAT OPTIONS

* A typical value is shown.
\# 3-4 would be for highly elliptical orbits and 10-12 would be for medium orbits (e.g. 200 km apogee).

As noted above there are at least three orbits appropriate for lightsats. For ease of comparison we can refer to low Earth orbit (LEO), elliptical Earth orbit (EEO) and geostationary orbit (GEO). The satellite orbit itself is not directly tied to the concept of small satellite. These orbits have pros and cons as shown in **Table 3**. These can be briefly summarized as follows. LEO has the advantages of small propagation distance, short propagation delay, low-cost and simple satellites, and small, low cost ground antennas. The disadvantages, however, are short visible time of pass, the need for many satellites to establish continuous service, and the likelihood that low gain, squinted omni antennas will provide limited capacity. EEO has an advantage of long visible time and a smaller number of satellites for continuous visibility. But its disadvantages are longer propagation delay, much fuel required usually, and the likelihood that tracking systems will be necessary. GEO has the advantage of no tracking requirement of the earth station, a minimum number of satellites, but the disadvantages are long propagation delay and higher cost of launching.

There perhaps two basic points of view with respect to the use of lightsats for a reasonable full service satellite telecommunication system. These are the international / regional type system and the domestic network. The international / regional service would likely best be accommodated by the LEO and/or EEO satellites where large numbers of lightsats would give broad coverage. The much more limited coverage of a domestic service on the other hand will often best be accommodated by a small GEO satellite. The following section illustrates both approaches.

2.2 Creating A New Data Network in the Asia-Pacific Region Using Lightsats

In order to cover the entire Asia-Pacific region a configuration of small satellites would be launched into LEO or EEO orbits. These satellites could be deployed so as to create a data network whereby the Pacific Rim countries and all the islands would have the ability to request information from data sources throughout the region or even around the world. Examples of the type of information that could be obtained might

include disease control information, agricultural research findings, economic forecasts, medical procedure information, and the latest advances in meteorological research. This system could have access to hospitals, for example, in the advanced countries and experts could give diagnostic, procedural, or pathology findings or advice to the requesting personnel. This system, however, would require very short turn around times for informational requests in order to save lives or to support urgent operational programs.

To keep the service response time rapid and to accommodate many users in order to provide enough revenues, the system would need a large number of satellite and large memory capacity. This in turn impacts the size of satellite, its complexity, and thus increases the total system investment cost. Instead, an alternative satellite system concept seems more appropriate. This would be a smaller scale non-profit communication system wherein a much longer turnaround or response time can be allowed but then only a smaller number of users can be considered. One might restrict users to universities, hospitals and/or medical research institutions. This means we can use very small LEO lightsats, and thus decrease the total cost to a very small amount such as $ 2-4 million. However, if it were decided to opt for a lightsat system that could be used to save lives, then near real time operation will be required which would suggest the elliptical orbit approach. These two options are discussed briefly below.

(i)LEO orbiting satellite system: Giving the small number of users and relatively long turnaround or response time, it is possible to design a quite inexpensive small LEO satellite system. If one proceeds with two LEO satellites of the so-called MACSAT design[3], it is possible to provide 2-6 hours write-to-read time which would support a great deal of information transfer. Each MACSAT would have 1.2 Mbytes on-board memory. Its 2.4 kb/s data transmission rate would provide 64 kbytes data transmission per orbital pass assuming the orbital configuration (e.g. 500 kilometer circular orbit) shown in Table 3. In the MACSAT system, users must share the 64 kbytes of data that can be transmitted per pass.However, the lightsat system considered here would presumably be restricted to a reasonable number of users. Therefore, there might be typically one, two, or three users per satellite pass.

(ii)EEO orbiting satellite system: The requirement of real time data transmission would require the use of one GEO satellite, three to twelve EEO satellites (depending upon the apogee of the elliptical orbit) or many LEO satellite system. The many LEO satellite system would be expensive. GEO system is also still expensive. There are, however, several systems using EEO. The most extreme of these is the highly elliptical orbit (HEO) satellite system of the U.S.S.R. known as Molniya. This system has been operational for more than 25 years, although recent Molniya launches have been placed into geosynchronous orbit. Recently, ESA has proposed the ARCHIMEDES (Advanced Research in Communications Highly Inclined orbits for Mobile applications and other Experiments and Demonstrations using European Satellites). Germany has proposed the LOOPUS (Geostationary Loops in Orbit Occupied Permanently by Unstationary Satellites). France has proposed the SYCOMORES system. These operating or proposed systems are used for the satellite communication in the high latitude area and would use relatively large satellites. On the contrary, the Phase III amateur satellite, OSCAR-13, is a small satellite whose weight is 142 kg. The propagation distance of the HEO satellite system is approximately the same as GEO satellite, around 38,000 km. Therefore, with this type of orbit a large EIRP is required of the satellite as well as a high gain antenna on the ground. It is still possible to design an inexpensive satellite system if the transmission rate is low, for example less than 9.6 kb/s. Another approach is to adopt the concept which is proposed with the Ellipsat system whereby an elliptical orbit with approximately a 2000 kilometer apogee is used in a configuration of 10 to 12 lightsats to cover a region rather than the entire world. In terms of satellite costs, launch costs, and earth station antennas, an information network for the Asia-Pacific region could be designed for less cost that a geosynchronous satellite system.

2.3 Small GEO Satellite--Domestic Communication System

A domestic satellite (DOMSAT) communications system for the Federated States of Micronesia (FSM) represents a good example of a small GEO satellite application. FSM was selected for this example because of the following factors: (i) The satellite communication is the optimum method to link such a configuration of islands. (ii) A small geostationary satellite is a plausible way to meet their domestic communication needs and to optimize the total cost. (iii) The FSM has a strong wish to build their own domestic communication system. (iv) An agreement to study this system will be obtained from the telecommunications authority of FSM.

According to the rough design of the system, the satellite size might be 90-130 kg, with 2 transponders on-board (one operational and another partially operational / partially redundant). A representation of the satellite and its coverage of FSM is provided in **Figure l.** One transponder could perhaps accommodate 150 64 kb/s circuits using 2.4 meter VSATs in the Ku-band with the bit error rate of $1x10^{-7}$ and link margin of more than 6 dB. If one were to use 16 kilobit /second voice, then a single satellite using one and a half transponder could support the equivalent of 900 voice channels. One could opt for one or two satellites with the second satellite to be launched in case of the primary satellite's failure. If the second satellite were indeed launched then it could be used to transmit four to six TV channels of 3 megabits /second compressed video. A very rough cost estimation shows that the total cost for the complete system could be approximately 150 to 160 Million Dollars including two satellites, their launches, insurance and ground facilities including a control station, a hub station, VSATs and terminal facilities such as telephones, faxs, tv sets, etc. The lowest cost, non-redundant start-up lightsat system would be perhaps $40 to $50 million..

3. HIGH CAPACITY SATELLITE PROJECT

This section addresses new 21st Century, high technology, high performance satellite communication systems that attempt to extend the state of the art beyond ACTS and the ETS-VI experimental satellite systems of the U.S. and Japan respectively. Unlike the lightsat systems considered in the previous section the attempt here to explore super high rate multi-gigabits / second transmission rates for "intelligent" satellite systems of the next century.

3.1 Needs of High Data Rate Transmission Satellite Communication System

In the ACTS (Advanced Communications Technology Satellite) project, a high data rate means 220 Mb/s to perhaps 622 Mb/s or SONET rate. The 1 Gb/s rate of data transmission for a single data link is for the Advanced Asia Pacific Telecommunications Satellite (AAPTS) somewhat arbitrary. but is considered a good benchmark to support supercomputer interconnection, 3-D Scientific Visualization, 3-D HDTV, desk-top video and other 21st century applications. Such a high speed data transmission can expand the application fields to a great extent. The need for high data rate transmission will at least include the following (See Reference 4):

-The nature of modern science and the types of scientific problems being addresses today demand unparalleled dynamic connectivity and major increases in bandwidth. There are growing needs for scientific high data rate transmission to support telescience, telecollaboration and remote access to proliferating, distributed databases. For example, the need to understand and monitor global change will likely generate 7000 terabytes of data over the next decade. This is an amount of information many times the total content of the U.S. Library of Congress.

-Simultaneous the remote database access is limited today by the ability of telecommunications services. There is a need for improved connectivity and increased bandwidth to provide remote users with access to central supercomputer capabilities. Enhanced X-window capability will reinforce this trend.

-There is a growing mismatch between the capability of telecommunications services actually available to users and users' needs and technical capabilities.

-Although the fiber optics technology is overtaking satellite capabilities in many areas, satellites still have unique areas of opportunity to supplement terrestrial fiber. Furthermore in certain areas like broadcasting, mobile services, and superlarge networks with extensive nodes, satellites still retain a significant edge.

-In the U.S., since the deregulation of telecommunications, a serious connectivity problem has developed due to lagging standards and the difficulty of orchestrating cooperation between the regional telephone companies and the hundreds of small independent companies.

The ACTS satellite will demonstrate very high data rate transmission[5]. The applications of this ??? on the ACTS include:

-NREN (National Research and Education Network): NREN is one of four HPCC (High Performance Computing and Communication Network) Program components. The goal of the NREN is to put in place a high speed (up to 1-3 Gb/s) fiber backbone for a research network that will provide a distributed computing capability linking the U.S. government, industry, and the higher education community. ACTS may have unique capabilities to extend the resources of the terrestrial fiber network to off-network locations.

-Supercomputing Applications: File transfer at rates up to 800 Mb/s requires wide-band networks. This capability will allow remote supercomputer sites to be linked with the main fiber backbone, and expanding the wide-band network to less populated areas.

-Remote Medical Imaging: As one of the supercomputer network applications, the remote medical imaging data flow from the CAT (Computerized Axial Tomography) Scan to supercomputer, to animation device, and to medical workstation.

-HDTV (High Definition TV) Applications: The HDTV technology can be applied to network/cable television, commercial/industry, graphic arts applications, medical and scientific applications.

-Scientific Applications: The above-mentioned NREN will support scientific visualization, X-window multiple database access, etc.

In addition to the above mentioned applications, the high speed data network using the AAPTS satellite in the Asia-Pacific region will have the following specific features:

-The 1 Gb/s transmission corresponds to 15,000 equivalent 64 kilobits/second voice circuits. This is many times the present communication capacity of many countries in the Asia-Pacific region. Therefore, the full 1 Gb/s rate capability would apply to only a limited number of high traffic areas in the region such as Los Angeles, Tokyo, Osaka, San Francisco, San Diego, Sydney, Taipei, Hong Kong, Mexico City, Singapore, Djakarta, Seoul and then perhaps reduced or partial rates for Vancouver, Peking, Kuala Lumpur, Manila, Auckland and so forth. Certainly to link such countries by significantly higher data rates will contribute toward accelerating the further development in the region tremendously. Every country in the region could still have the opportunity to plug into this multi-gigabit satellite at some appropriate data rate using the regional beam.

-The service area is very large and dispersed in the Pacific region. Then the network completely covered by fiber cables will be unable to be applied for economic reason. The satellite and/or hybrid satellite and fiber technology are very appropriate in this region.

-However, the need of such super-high data rate is still not well market justified especially in the commercial business field. Thus the development of such a high performance satellite has a technology development aspect.

3.2 Design of Experimental Communications Technology Satellite

An advanced communications satellite system envisioned in this study would provide not only 1 Gb/s data rate transmission links to selected cities in Asia-Pacific countries, but would also have a multi-gigabit/second total capacity. It is important, however, to design the satellite as a practical operational prototype that could be placed into commercial service after initial tests and demonstrations are complete. A facility of this complexity, cost, and program dimension is too grand of undertaking for simply experimental purposes. By combining U.S. and Japanese resources and obtaining a commitment from commercial sources such as INTELSAT, NTT, KDD, AT&T and others a strategy of experimental satellite migrating to operational service could potentially be devised. The idea is thus to seek aggressively an important new and challenging technology development without undercutting the viability of operational use and recouping of an investment that would at least be many hundreds of millions of dollars. The basic concept of this study option is provided in **Figure 2.** The key issues to be considered with respect to this study option are enumerated below. It should be noted that other approaches are being addressed in the full study under the NASA grant and that these include a high data rate satellite that includes the feature of bit by bit processing and on-board signalling as well as other even more advanced concepts which are discussed in Section 4.

(i)Service Area vs. Number of Satellites: The Asia Pacific region is located over some 200 degrees of longitude: from 80 degree East to 80 degree West. This means that any one satellite can not cover the whole region. In addition, the higher frequency band is assumed in order to achieve high data rate transmission. The higher frequency band communication link, however, suffers much more rain attenuation. Since, low elevation angles are not desirable a two satellite system with intersatellite link is one possible approach. The inter-satellite link will be useful to avoid rain attenuation in the double hopfeeder link it slightly decreases propagation time. Assuming that the two satellites are located at 150 degree East and 120 degree West, respectively, the distance between two satellite is 90 degrees of longitude and about 59,400 km. The delay time increases by 42 ms for each way in comparison to the case that double hop interconnection on feeder links are used. Since the inter-satellite link would be required to communicate several Gb/s, the optical communication technology will be appropriate.

(ii) Number of Cities vs. Number of Antenna Beams: Many high data rate beams can be accommodated unless there is a need for close co-location of the beam patterns. Fortunately, the contiguous beam coverage will not be required for the service area in this satellite, since each city is located at sufficient distance apart throughout the vast region of the Asia-Pacific. In a few exceptions like Los Angeles and San Diego a single beam can be used. Therefore the multibeam antenna itself can be designed from a technical point of view with a high degree of efficiency. Here two 6 beam satellites are examined as an example.

(iii) Frequency Band: The service points are located separately from each other and each beam width is very sharply defined in order to obtain the high EIRP. Thus frequency reuse can be established relatively easily. However, since at least 1 GHz bandwidth is needed for what might be called the super beams, the Ka band and/or millimeter wave band will be appropriate. For the inter-satellite communication, the optical wave is the most appropriate to obtain several Gb/s data rate transmission.

(iv) Link Parameters: According to the link budget, the on-board antennas would need to be of 220 wave length diameter (3.3 m for 20 GHz and 2.2 m for 30 GHz). This would also require a regenerative type of transponder and earth stations of 5 m diameter antenna and a 100 W output power transmitter to accommodate a 1 Gb/s data transmission in the Ka band with a link margin of more than 6 dB and the bit error rate of 1×10^{-7}. Higher level bit error rate performance would be achieved through coding as needed.

(V) Inter-Satellite Link Capability: The inter-satellite communication link would be optical because of the high bit rates. However, the optical space communication technology itself is still relatively immature and this would be one of the key R&D objectives of the project. In short, much improvement of optical ISL technology will be needed over the next five years to allow the particular project to go forward. For purposes of illustration the 2 Gb/s optical intersatellite link is considered here.

(vi) Configuration of Satellite System: Two satellites, assumed to have almost the same size and mass as ACTS will be connected by optical inter-satellite communication link. It would have 6 super beams, plus one broad coverage beam for regional interconnectivity. The six super beams would be created by two on-board antennas produces the system configuration as shown in **Figure 2.** The regional coverage beams are not shown but would be like a modified INTELSAT regional beam.The total bandwidth of this satellite is approximately 10 GHz (6 superbeam satellite-earth links, 1 regional beam and 2 inter-satellite links). To organize the satellite as a realizable 2 ton class satellite would be one of the key points of technology development.

4. NEW CONCEPTS FOR 21ST CENTURY SATELLITE SYSTEMS

4.1 Examining and Evaluating New Ideas

In recent years there has been considerable stress on the idea that the U.S. and Japan are locked in various forms of competition related to trade, technical innovation, management and productivity.
It seems important in this context to recognize that these countries natural trading partners, and that in the context of the Asia-Pacific region Canada, Mexico, Japan, and the U.S. are each others primary trading partners. The future of the U.S. and Japan are in many ways riding of the success of the Asia- Pacific region and if there are new and innovative ways to collaborate within the region it will likely be to their mutual benefit. Some of the ideas that follow are new and unconventional but even so they hold the potential and promise of a new Century.

4.2 New Ways to Use GPS Packages On Low Orbit Satellites in the Asia-Pacific Region to Monitor Global Warming.

There are today dozens of satellites equipped with Global Positioning Satellite receivers for navigational purposes. The number of these GPS satellites in low earth orbit are scheduled to increase dramatically in the next few years as lightsat mobile satellite systems are deployed. It is possible to use this capability not only for navigational aids and mapping, but this capability can aid with the so-called mission to planet earth and in particular with the monitoring of the earth's atmosphere. The creation of complex computer models and conversion formulas can allow derivation of atmospheric density, atmospheric temperatures at different altitudes and even atmospheric composition. The key to this operation is that radio occultation measurements between GPS satellites and low orbit satellites with GPS receivers can be inverted to provide critical data. In particular they provide refractivity profiles, from which new computer models now being developed in the USSR and at NCAR in the US can calculate density, pressure and temperature. These are not yet totally accurate models and reading accuracy can be affected by water vapor variability. Nevertheless, accuracy in the range of 2 degrees K accuracy is estimated for tropical rain forest areas at altitudes below 8 kilometers. In the rest of the accuracies of 1 degree K is estimated for the atmosphere at altitudes of 7 to 35 kilometers.

This is a remarkable new effort that indicates that global atmospheric monitoring could move ahead much more quickly than previously thought possible. The coordinated effort to use GPS receivers in this manner throughout the Asia-Pacific Region would be appear to be an important humanitarian role that the U.S. and Japan should actively support and provide active financial support in order that this undertaking could be accelerated. (See Reference 6).

4.3 New developments in USAT (Ultra Small Aperture Terminal) technology to aid rural and remote services.

The evolution of satellite communications has been described as that of "technology inversion". This simply means that over time satellites have gotten larger, more powerful, more "intelligent"

and more capable. At the same time the earth station antennas on the ground have gotten smaller, used less power, become more mobile and light weight, and decreased greatly in cost and price. This is a logical transition from an economics and service perspective. Since there is just one satellite per service area but a very large number of earth station antennas, if you can transfer the function to the satellite you only have to do it once as opposed to hundreds or thousands of time. With the advent of on-board processing as demonstrated by ACTS and ETS-VI, a new capability comes to the fore in terms of having the satellite connect remote antennas directly to other remote antennas, rather than interconnection through a hub or star configured master antenna. Suddenly satellites do not have to be hierarchically arranged like a terrestrial network. All antennas in a service area can connect directly to each other. This suggests that in the future very large "mesh configured networks" can be used throughout large regions with a high degree of cost efficiency. It not surprisingly gives rise to concerns about bypass of established telecommunications networks as well.

The key to this dramatic new capability becoming possible is truly low cost and compact ground antennas. In the past 5 years, VSAT technology has burst on the scene. INTELSAT has gone from 3 earth station standards including the 30 meter Standard A to 13 standards that includes a 75 centimeter INTELNET receive only antenna not much different in size than a pizza pan. This trend is far from over. The GEOSTAR network developed a receiver with a very low rate return channel that looked and felt a lot like a garage door opener device, and weighted the same as a book. The Jet Propulsion Laboratory (JPL) is designing a very small mobile antenna for a car or truck which will be tested with the ACTS satellite. In more advanced studies, JPL is doing a design study for a personal communications system that would use a very small hand held transceiver, and even more dramatically there are some 8 mobile satellite systems that have been filed in the United States for a direct to the subscriber mobile service to supplement cellular radio systems. Some of these systems such as Globestar and Iridium are intended to be mobile in scope.

The key point is that today we are being to transition from antennas in the 1.2 to 3.0 meter range which we call VSAT, to a new era that is defined by antennas (often conformal phased arrays) that are 50 centimeters or below in diameter. The applications with initially be for lower data rates and very low speed "recognizable" voice (e.g. 1.2 kbit/s) but they will grow over time. The applications are today varied and important. These applications include remote power readings, emergency alarm systems, weather alerts, network management controls for oil companies, shipping lines, etc. These technologies could have immediate application in many Pacific island countries today, especially where no communication capability now exists.

A concerned effort to build "smart" computer assisted USAT antennas, using phased array antenna technology is another "leveraged project" where U.S. and Japanese cooperation might assist the region and their earth station manufacturing industries.

4.4 Concept Studies to Create 21st Century Satellite Systems That Have High Performance and Reliability With Minimum Transmission Delay and Easy Interconnection Into Terrestrial Systems.

The easiest tendency is to look at history as linear with steady ranges of change over time. Any student of history knows that progress and regression tends to come in spurts. The satellite industry with development of lightsats, low-orbit mobile satellites, USAT, and "intelligent" satellites is currently in the midst of what seems to be a significant thrust forward. The challenge of fiber optic cable and the drive to create super reliable, super fast, error free networks with virtually no transmission delay and "streamlined" overheads in data cells all suggest that satellites need a major paradigm shift that goes beyond conventional geosynchronous satellite technology. Under studies now under way at the University, totally new concepts are being evaluated as to their feasibility in terms of technology, operational viability, financial cost , frequency allocations, health and safety factors and technical standards.

These concepts vary greatly in terms of cost, technical feasibility, and dates of possible implementation. Those under active study at this time are listed below to show the diversity of approaches that could become possible at a future date:

(a) Optical Satellite Cables in the Sky: The transmission of optical signals can clearly be accomplished across space. A 60,000 kilometer ISL connections is, in fact, presented in Section 3. The problem is getting an optical signal from the earth surface to above the atmosphere. One proposal is to use aerostats tethered by optical fiber as the cablehead for space transmission.

(b) Drone-Stablized Geosynchronous Platforms in Low Earth Orbit. If this concept could prove economically feasible and operationally reliable, then it could solve some major problems with transmission delay, path loss, antenna pointing, and overall capacity and performance. NASA experimented with this concept over a decade ago and abandoned the project. Creating drone planes with the cybernetic capabilities needed for long term operation may now be within reach. The environmental aspect of such a concept would need particularly close scrutiny.

(c) A Ground Based Power Transmission System for Stabilizing a "Spidersat" in Low Earth Geosynchronous Orbit. The idea of a low earth geosynchronous orbit is not new. Arthur Clarke wrote of it over a decade ago. He has indicated, however, that he was not certain how it would or could be done. The SHARPS project in Canada has perhaps indicated through its ground powered microwave transmission to a drone plane flying up to 13 miles high how it could be done. If you could build a satellite that weighted only 20 kilograms, it would be possible to stabilize it at an altitude of some 500 miles with transmission of about 50 kilowatts. (This is equivalent to powering a Honda or Ford Escort at about 45 miles per hour). You might as what good would a 20 kilogram satellite, but with no solar cells or batteries or stabilization, all that would be needed is mylar antennas and microcircuitry. This "Spidersat" might be able to generate a million equivalent voice circuits. or provide a thousand video channels.

This is not a complete list of advanced concepts but it does help underline the fact that there still some new ideas and possible new innovations for the field of satellite communications in the 21st Century. Cooperation in advanced concepts is thus yet another way that the U.S. and Japan could work together in the next century.

5. CONCLUSIONS

This article is but a brief resume of a much longer report and study. When completed the projects selected for recommendation detailed feasibility study may be different from the various projects selected for discussion here. One conclusion, however, seems very clear and that is there are many promising areas where U.S. and Japanese cooperation could be highly productive, economic, and extremely useful to the entire Asia-Pacific region. As a tribute to International Space Year 1992 it would seem highly appropriate for some these preliminary projects to be selected by the U.S.-Japan Committee for detailed review and study with a view to selecting two or three projects for implementation.

The results of these studies will be presented to NASA, the Japanese MPT and NASDA, and the U.S.-Japan Committee to determine their feasibility for implementations.

1. ABSTRACT

The transportable earth stations were developed for the purpose of Pan-Pacific Information Network Experiment using Engineering Test Satellite V (ETS-V) satellite. ETS-V has two antenna beams and covers north and south-west part of Pacific ocean. 64 kbps QPSK was employed for the system. 64 kbps full-duplex satellite link enables TV conference or multiplexed voice and data communications.

2. PAN-PACIFIC INFORMATION NETWORK EXPERIMENT

2.1 OBJECTIVES OF THE EXPERIMENT

This experiment is carried out using ETS-V in the L-band frequency for the Pan-Pacific information network study. The Pan-Pacific information network for mutual communication and information exchange specially for non-profit, educational purpose is desirable to be constructed by using low cost and simple earth stations. For the future network, digital technology, especially, visual communication is important to study. Therefore, the objectives of the experiment are summarized as follows;

(1) To show applicability of 64 kbps digital satellite link.
(2) To discuss operationability of L-band frequency.
(3) To study how to manufacture the simple and low-cost earth station.
(4) To find requirements of the future satellite system.

2.2 CONFIGURATION OF EXPERIMENTAL SYSTEM

Fig. 1 shows L-band antenna coverage of the ETS-V. The communication experiments are carried out between Japan and Hawaii. In this case, position of Hawaii is edge of the north beam, and the satellite antenna gain is 7 dB lower than that in Japan. In order to keep receive signal quality, the bigger antenna is prepared for the transportable earth station.

L-band to L-band loop-back mode of the satellite transponder is used for this experiment. Therefore, Two earth stations for both side of the satellite link were developed.

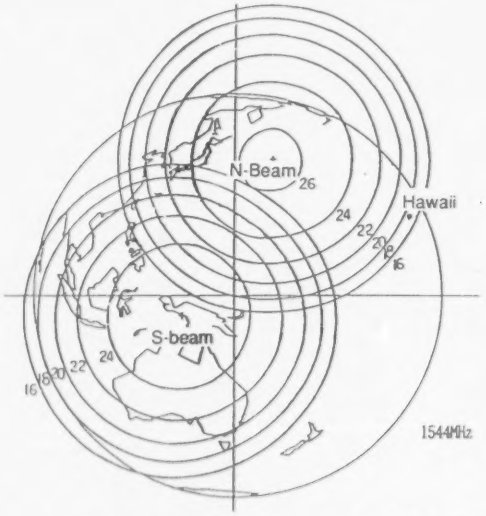

Fig. 1 L-band Antenna Coverage of ETS-V

64 kbps digital transmission link was selected for the basic satellite link, in order to communicate with both voice and compressed video signal. TV telephone signal can be transmit with 64 kbps satellite link. Furthermore, 64 kbps digital data can be divided into the voice channels and data channels.

3. DEVELOPMENT OF TRANSPORTABLE EARTH STATION

3.1 SPECIFICATION OF EARTH STATION

The configuration of the transportable earth station is shown in Fig. 2. The earth station consists of the outdoor unit and indoor unit. The outdoor unit

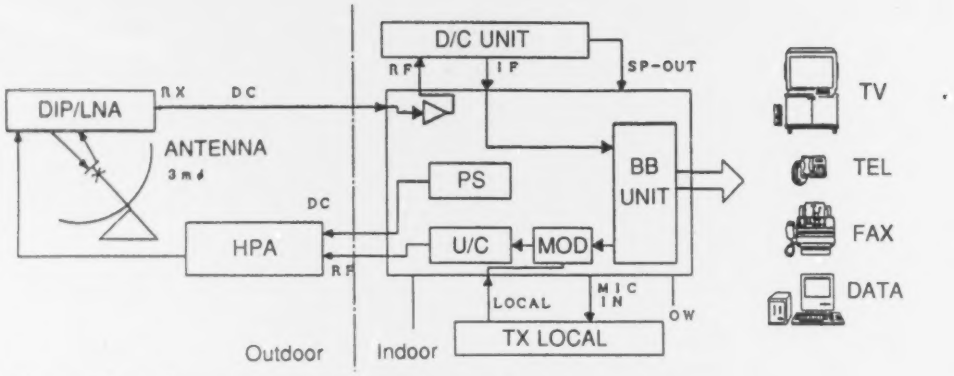

Fig. 2 Configuration of Transportable Earth Station.

includes the antenna, high power amplifier (HPA) and the low noise amplifier (LNA). The indoor unit divide into three boxes which are the amateur radio transceiver, general coverage receiver and the developed digital modem. The amateur radio transceiver is used for the carrier generator for QPSK modulator and FM signal generator for the voice communication. The general coverage receiver is used for the receive frequency down-converter, and IF output of the receiver is connected to the QPSK demodulator. Summary of the main specification is shown in Table 1.

Table 1. Specification of Transportable Earth Station

TX Frequency	1644 - 1645.5 MHz
RX Frequency	1542 - 1543.5 MHz
Antenna	3m diameter Parabolic
HPA	GaAs FET 10W Linear AMP
Modem	Data link: 128kbps QPSK Voice link: Narrow band FM
FEC Coding	Convolutional Coding (R=1/2, K=7)
FEC Decoding	Viterbi algorism, 4bit Soft Decision
Data rate	64kbps TV conference
Multiplexed Data	16kbps Voice Data: 2CH 9.6kbps FAX Data : 1CH 4.8kbps PC Data : 2CH
Voice Coding	Adaptive delta modulation

The convolutional coding, Viterbi decoding algorism is employed for the forward error correction (FEC). The FEC coding rate of 1/2 is selected. Therefore, 64 kbps of data rate is converted to the 128 kbps RF transmission rate. In order to minimize the band-width, QPSK modulation technique is employed for L-band to L-band link of the satellite transponder which total band-width is limited to 300 kHz.

3.2 LINK BUDGET OF ETS-V

The link budget of the L-band to L-band satellite link of ETS-V is shown in Table 2. Two signal from each earth station are amplified by the satellite L-band transponder, when the full duplex communication is carried out.

Table 2. Link Budget of ETS-V

TX earth station	Tokyo	Hawaii	
RX earth station	Hawaii	Tokyo	
TX Power	2.5	5.9	dBW
TX EIRP	34.1	35.9	dBW
Propagation Loss	188.3	188.0	dB
Satellite G/T	-4.7	-10.4	dBK
Up-link C/No	69.7	66.2	dBHz
Satellite TX PWR	7.0	3.5	dBW
Satellite TX EIRP	19.5	23.6	dBW
Propagation Loss	187.7	187.7	dB
Earth station G/T	6.5	6.5	dBK
Down-link C/No	66.9	70.5	dBHz
Total Link C/No	65.0	65.0	dBHz
Required C/No	56.0	56.0	dBHz
Link Margin	9.0	9.0	dB

Notes) Antenna diameter: 3m
Back-off of the satellite transponder: 3dB
Implementation Loss: 4dB

The link budget shows that the full-duplex communication link is available with 9 dB of the link margin.

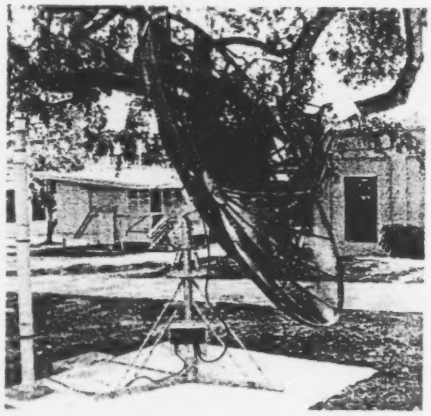

Fig. 3 Antenna System.

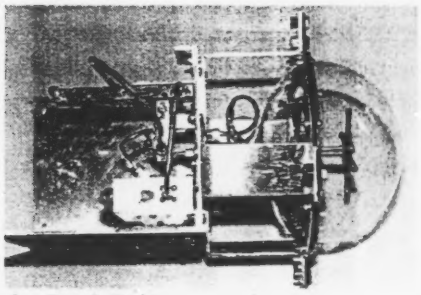

Fig. 4 Feed Unit.

3.3 RF SYSTEM OF EARTH STATION

1) ANTENNA SYSTEM

Fig. 3 shows the antenna system. 3 m diameter mesh type parabolic reflector is used for the antenna. Fig. 4 shows the feed unit which include the cross dipole antenna, the diplexer and the low noise amplifier. The 10 W high power amplifier is installed on the base pole.

2) DIPLEXER

The diplexer is used for the full-duplex system. The diplexer works as an isolator between transmitter and receiver. The functions of the diplexer are to attenuate TX signal at the LNA input, and to attenuate the noise power from the HPA at receive frequency. Fig. 5 shows the signal levels around diplexer.

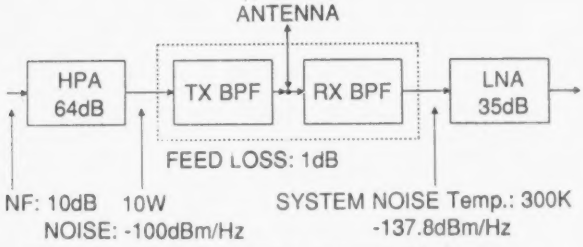

Fig. 5 Signal Levels Around Diplexer.

Since the gain of the LNA is about 35 dB, input signal level of the LNA should be less than -40 dBm, in order not to saturate the LNA. Therefore, the attenuation of the RX band-pass filter (BPF) in the diplexer should be higher than 80 dB, in case that the transmission power is 10 W.

On the other hand, the wide band noise generated from the HPA should be attenuated by the TX BPF in the diplexer. As shown in Fig. 5, receive noise level at the LNA input is estimated to be -173.8 dBm/Hz, when the RX system noise temperature is 300 K. Since the noise power at the HPA output is estimated to be -100 dBm/Hz, the attenuation of the TX BPF in the diplexer should be higher than 80 dB.

Fig. 6 shows the diplexer unit. In order to reduce the size and weight of the diplexer, the di-electric resonator is used for the filter element. In this case, the attenuation of the diplexer is 65 dB. Therefore, simple BPF is added after the diplexer.

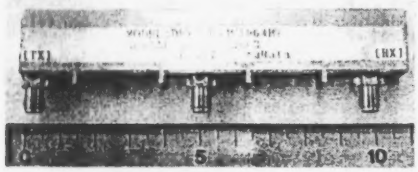

Fig. 6 Diplexer Unit.

3) LNA

Conventional LNA is used for the earth station. Noise temperature of the LNA is 70 K.

4) HPA

Fig. 7 shows the block diagram of the HPA unit. A GaAs FET power module is employed as a main amplifier. In order to reduce the wide band noise generated from the power amplifier, BPFs are inserted at the input and output of the amplifier.

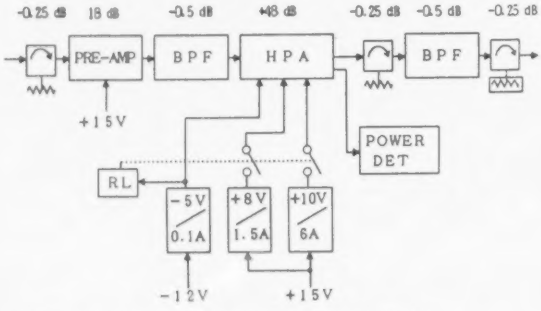

Fig. 7 Block Diagram of HPA Unit.

The linearity of the HPA is shown in Fig. 8. The maximum output power at 1 dB compression point is 41 dBm. The noise spectrum of the HPA is shown in Fig. 9. The carrier to noise power density ratio at TX frequency is about 139 dBHz. The noise power density at RX frequency is less than -150 dBm/Hz. Since the noise is attenuate 65 dB by the diplexer, the noise does not affect the receive system noise.

5) RX FREQUENCY DOWN-CONVERTER

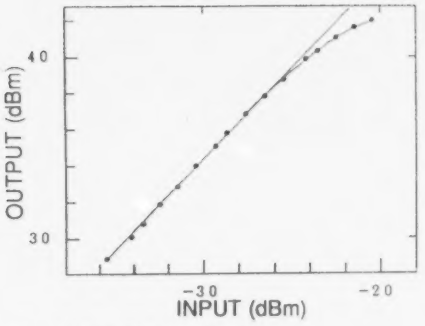

Fig. 8 Linearity of HPA.

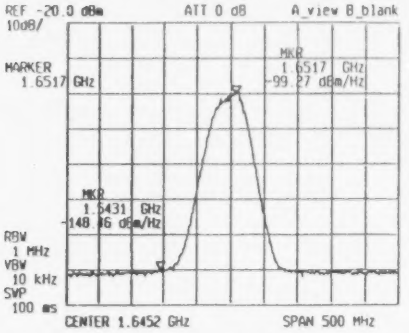

Fig. 9 Noise Spectrum of HPA.

A General coverage receiver is used for the RX frequency down-converter. The stability of the receiver is 0.25 PPM, and receive frequency at L-band can change 10 Hz step. Fig. 10 shows the Phase noise performance of the receiver. Since the phase noise level at 1 kHz offset point is 66 dBHz, this receiver can be used for the 64 kbps data transmission.

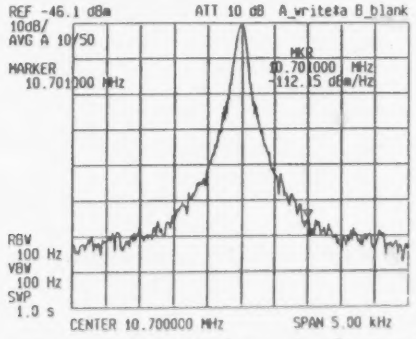

Fig. 10 Phase Noise Performance of Receiver.

6) TX FREQUENCY UP-CONVERTER

Fig. 11 shows the block diagram of the TX frequency up-converter. 145 MHz TX IF signal is up-converted to the L-band

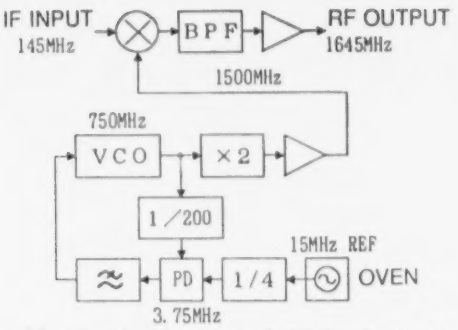

Fig. 11 Block Diagram of TX Up-Converter.

signal with 1500 MHz local signal. The local signal is generated by using 750 MHz phase lock loop oscillator which is locked to 15 MHz oven controlled reference oscillator. The frequency stability of the local oscillator is within 1 kHz.

The phase noise characteristics of the local oscillator is shown in Fig. 12. The C/No of the local signal has obtained to be 95 dBHz at the 40 kHz offset point from the local frequency.

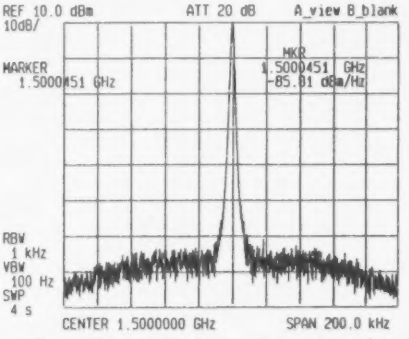

Fig. 12 Phase Noise Characteristics of Local Oscillator.

3.4 QPSK MODEM UNIT

1) QPSK MODULATOR

The configuration of the QPSK modulator is shown in Fig. 13. In order to simplify

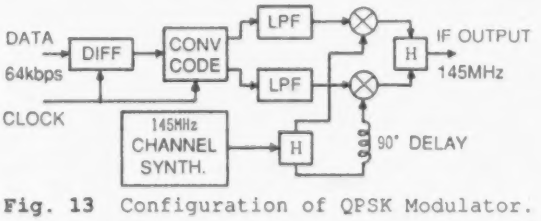

Fig. 13 Configuration of QPSK Modulator.

the circuit, two data streams at the

output of the convolutional encoder are connected to I and Q channel of the quadrature modulator respectively. The differential encoding before the convolutional encoding is prepared to solve phase ambiguity problem at the receiver. A seven stage convolutional encoder is used as shown in Fig. 14.

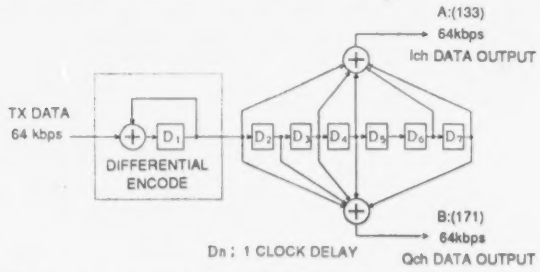

Fig. 14 Convolutional Encoder.

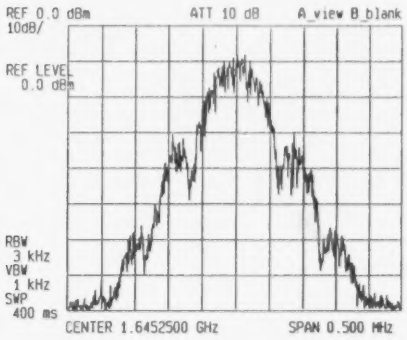

Fig. 15 Spectrum of Modulated Signal.

Fig. 15 shows the spectrum of the modulated signal. In order to reduce the band-width of the modulated signal, The LPFs of BT = 2 are adopted at the input of the quadrature modulator.

2) QPSK DEMODULATOR

Fig. 16 shows the configuration of the QPSK demodulator unit. 10.7 MHz received IF signal is demodulated by using the Costus loop carrier recovery circuit. The clock signal is regenerated from the signal transient of the I channel demodulated signal by using the digital PLL clock regenerator. I and Q channel of the demodulated base-band signal is quantized to the 4 bit data respectively, and input to the Viterbi decoder IC.

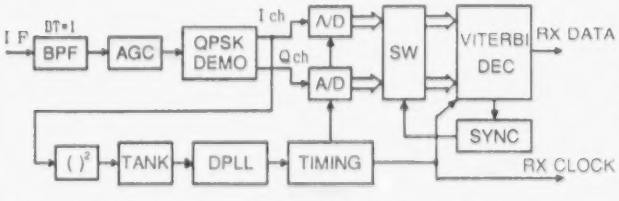

Fig. 16 Configuration of QPSK Demodulator

3) VITERBI DECODER

In order to solve the phase ambiguity problem of the QPSK demodulator, the exchange switch and data invertor circuit is needed at the data input of the Viterbi decoder. In case that the recovered carrier phase has 90 or 270 degree offset from TX modulator, the Viterbi decoder cannot decode correct data because the I/Q channel data is replaced by the Q/I channel data. Therefore, the data exchange and invertor circuit works when the Viterbi decoder output the error flag.

In case that the recovered carrier phase has 180 degree offset, The Viterbi decoder works correctly and outputs inverted data. Data inversion can be solve by using differential decoding circuit.

3.5 BASE-BAND UNIT

1) DATA MULTIPLEXER

The data multiplexer and demultiplexer is prepared for the voice and data communication using 64 kbps modem. Two channel of 16 kbps voice data, 9.6 kbps of the FAX data, two channel of 4.8 kbps PC data and the frame synchronization data is multiplexed to 64 kbps data. Fig. 17 shows the frame format of the multiplexed data. One frame consists of 40 bits of data. 8 bits of the frame synchronization pattern is put to the top of the frame. The data scramble pattern is multiplied to the 32 bits of the data part.

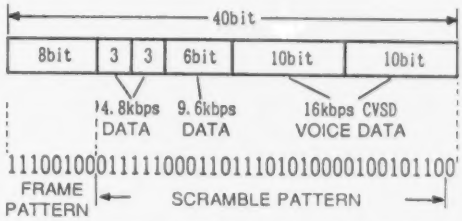

Fig. 17 Frame Format of Multiplexed Data.

2) DATA DEMULTIPLEXER

The configuration of the data demultiplexer is shown in Fig. 18. The demultiplexer detects the frame synchronization pattern and divide each data to respective data rate. In order to simplify the frame synchronization control, the frame counter is initialized under the condition of a series of four frame pattern detection. The probability of false synchronization can be calculated as $1/2^{32}$. This value is about 2.3E-10, and small enough for the simple earth station.

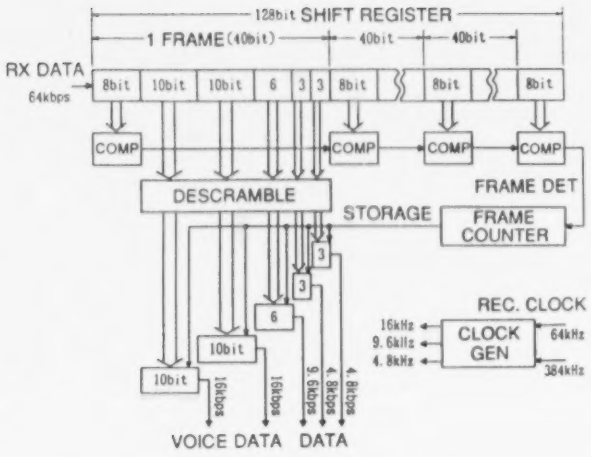

Fig. 18 Configuration of Demultiplexer.

3.6 TV CONFERENCE SYSTEM

The connection of the video equipments is shown in Fig. 19. 64 kbps TV telephone system (INVITE 64) is used as the TV signal codec. Normal TV telephone system need not the echo canceler, because the headset or handset is used both side of the station. However, the echo canceler is essential for the TV conference, in order to reduce the echo generated in the conference room.

4. CONCLUSIONS

The low cost transportable earth stations were developed for the Pan-Pacific information network experiment, which is started between Japan and Hawaii. The first TV conference experiment was carried out between Kobe, Japan and University of Hawaii, for Symposium on the Establishment of a Pan-Pacific Information Network on Nov. 1990. Through this experiment, 64 kbps TV telephone codec gave us enough information in the conference, and we could find easily who was a speaker, or we could read the viewgraphs with big character.

L-band frequency is easy to handle because the transistors and ICs are available. Therefore, the frequency band from 1 to 2 GHz is the best for these kind of simple satellite communication projects.

For the Pan-Pacific information network experiment, we have finished the earth station with low cost. However, we realized that the wiring of the logic circuits is a time consuming job. Therefore, we decided to use the computer aided design tools for the field programmable logic array or logic cell array instead of wired circuit board for the new earth station. The improved video codec which meets CCITT standard H.261 is also under development.

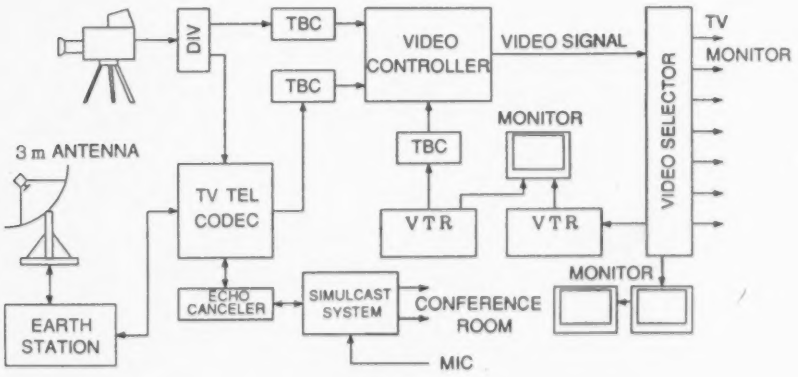

Fig. 19 Connection of Video Equipment.

ACKNOWLEDGEMENT

We would like to thank Prof. Topping, Ms. Mukaida and PEACESAT people of University of Hawaii for their cooperation and encouragement. We also thank the people concerned of CRL, MPT, NASDA, Tohoku University, University of Electro-Communications, Kobe University, Hyogo Prefectural Government and the Organizing Committee of PAN-NET'90 for their support and cooperation. A part of this work is supported by the Okawa Institute if Information and Telecommunication and Research and Development Center for Radio Systems.

OVERVIEW TO ASEAN REGIONAL TELECOMMUNICATIONS DEVELOPMENT INTERESTS IN A GLOBAL ENVIRONMENT

MARK A. HUKILL, Ph.D.
NGEE ANN POLYTECHNIC
SINGAPORE

ABSTRACT

A broad overview to the regional interests of the ASEAN countries in developing telecommunications and information systems is presented in the context of global issues of systems and services growth as well as policy evolution. A mosaic of interrelated issues are discussed in order to understand the context of ASEAN as a regional force capable of affecting significant impact on the global telecommunications environment.

1. INTRODUCTION

The 1990s may well be looked at as landmark years for the development and assertion of regional interests of the ASEAN (Association of South East Asian Nations) in a global environment. The ASEAN countries have renewed pledges and strengthened action plans toward building a lasting peace in the region as well as developing cooperative measures for the enhancement of economic development. Without a doubt, events in Eastern Europe, the European Community, the Soviet Union and Middle East have and continue to occupy our attention internationally. Nonetheless, a real dynamism (if less dramatic) in terms of working toward a political maturity and economic development rests squarely with the Asia-Pacific region. The ASEAN countries in particular are becoming a collectively strong player in the development of trade relations, industrial and information sector growth as well as a leader in regional development with global implications. As global services and systems become more the norm of operation in telecommunications, strengthening national and regional systems has become a major priority for the ASEAN countries. This is being done not only to bring up the quality and quantity of infrastructure and services to meet an ever increasing demand domestically, but also to be positioned to both cooperate equitably and compete selectively in expanding global markets.

With the recent positive progress toward a lasting resolution of the Kampuchea (Cambodia) issue and the beginnings of change toward economic and political cooperation with the entire Indo-China region, the ASEAN countries have begun to succeed in the task of developing cooperative and consultative relations with each other and with other nations in the region to solve political disputes. These political links are translating rapidly into economic links and telecommunication development has become an important part in the realization of development goals. The ASEAN countries are responding quickly to telecommunications development needs in Laos and Vietnam with Kampuchea not far behind. Sights are now set on beginning to ease the strained relations with Myanmar (Burma). The whole of Southeast Asia is nearly poised to begin a developmental period which will launch the region, during the rest of the 1990s, into becoming a major player in the international arena.

Sophisticated regional economic cooperative links are being forged in the wake of increasing political stability. As the political and economic clout of the ASEAN countries continues to grow, regional telecommunication interests in mobile systems, satellites and undersea cable systems, as well as rapidly growing value-added services are of primary concern. The integration of these services and systems with both global

networks and developing domestic basic infrastructure is becoming an increasingly complex task. Pressure to reorganize government owned, monopoly telecommunication authorities continues.

At the same time, these organizations are expanding internationally and are beginning to assert concomitant interests in international trade relations. However, while some reforms are evident, the revision of policy and internal practices tend to lag behind these developments creating a cumbersome brake on otherwise well intentioned change for both domestic development and international expansion. A mosaic of interrelated issues are presented in this paper to better understand the context of the ASEAN's development into a regional force capable of affecting a significant impact on the global telecommunications environment.

2. ASEAN ECONOMIC INTERESTS

A new economic framework agreement was accepted in late 1991 which sets a clear direction for a workable cooperation among the ASEAN nations. This framework agreement is aimed at creating a regional free trade area within the next 10-15 years. Originally proposed by Malaysia as the East Asia Economic Group (EAEG) in early 1991, the ASEAN countries have since agreed to the term EAEC or East Asia Economic Caucus after combining different proposals from member states. The purpose of the caucus is to eventually lead to building an Asian Free Trade Area (AFTA) among not only the ASEAN countries but also other East and South East Asian nations including Japan.

These economic cooperation developments are significant for a number of reasons. Primarily, they point to an increasing regionalism taking shape as political stability and good regional relations are fostered. This regionalism is in part a response to the development of regional trade groupings elsewhere and the competition it represents including the consolidation of the European Community and the development of a North American Free Trade Area.

Other regional organizations continue to build upon the evident goodwill shown primarily through the renewed strength of the ASEAN grouping. The Asia Pacific Economic Cooperation (APEC) was initially concerned that the development of an Asian Free Trade Area under the sponsorship of the EAEC would undermine APEC primarily as the EAEC does not include the United States. Whether APEC's role is diluted as a result of more compact regional agreements is yet to be seen. It seems however that the trend in the region for growing economic linkages will allow such forums as APEC to begin to assert itself in terms of removing barriers to trade, promoting further investment and developing technology, information and people.

Nonetheless, such regional structuring has not prevented bilateral trade agreements from being formed at the same time. Recently, Singapore signed a Trade and Investment Framework Agreement (TIFA) with the United States. While some may find that such bi-lateral arrangements are an effort on the part of the U.S. to purposefully circumvent the EAEC, a more lucid analysis would find that such arrangements are pragmatic to both parties and allowable under the ASEAN agreement despite a trend to greater regionalism.

Underlying the new economic trade relations, and their corresponding increase in activities, are important changes to the economies of individual countries in the region. Many have prospered with over 50% of the exports of each country consisting of manufactured goods. The ASEAN economies are beginning to achieve comparative advantages in different sectors as the gap between the most developed of the group, Singapore, and the lesser developed countries of the ASEAN is closing.

Major investment and development plans have been implemented including the concept of 'Growth Triangles' which focus on the advantages of each of three bordering countries concerned in furthering economic development. The 'Growth Triangle' concept is currently being put into practice in the development of the region between Johor State in southern Malaysia, Singapore and the Riau Islands of Indonesia. Efforts are primarily concentrated on two relatively large Indonesian islands, Batam and Bintan, which lie just a few miles southeast of Singapore. Investment in manufacturing, tourism, transportation and telecommunications in this growth triangle area already total more than $1 billion with Singapore providing some 40% of the investment funds. Interestingly, such investments have had the side effect of propelling the Singapore dollar toward becoming an international currency, yet another indicator of the growing economic dynamism of the region. Indeed Singapore, for all intents and purposes, will be a developed nation by the year 2000. Malaysia has ambitious plans to follow suit by 2020.

3. REGIONAL TELECOMMUNICATIONS EVOLUTION

ASEAN regional economic cooperation has lead to the development of many new relations in various sectors of the economies of the nations concerned including the development of telecommunications systems. In the Growth Triangle arrangement for example, Singapore Telecom has entered into a joint venture development with PT Telekom (formerly PERUMTEL) of Indonesia, the Salim Group and other private concerns to develop the telecommunications infrastructure on Batam and Bintan islands. The new telecommunications facilities, primarily basic services and an international gateway, coincide with the manufacturing and tourism industries being developed. In fact, a shift in policy toward foreign ownership of telecommunications facilities in Indonesia was made to fit the specific development needs of the situation. A joint venture arrangement allows Singapore to both own and operate the basic systems through a revenue sharing scheme for an extended period before finally transferring the system to Indonesia. Such an arrangement has been possible only through the very pragmatic developments in trade relations and an increasing reliance on the various strengths of regional countries to enhance development efforts within each other's country.

Trends toward various forms of privatization, private participation and deregulation in telecommunications in the ASEAN countries have been noted previously.[1] In Singapore and Malaysia in particular where privatization of the telecommunications authorities are in various stages of progress, the need to expand beyond the domestic markets are evident. [Several papers in this Proceedings deal with privatization in the ASEAN countries: 3.2.3.5, 4.3.3.4, and 4.3.3.5.] Singapore Telecom is currently involved in various joint venture and consultancy roles in many countries in Asia. Both Singapore and Malaysia are looking toward developments in Vietnam as relations with that country are soon to be normalized. In fact, the political situation is such that open discussion on the possibility of Vietnam becoming the seventh full member of ASEAN has ensued. Efforts are beginning now for ASEAN member countries to take advantage of their own strategic position in providing telecommunications expertise and investment to Vietnam as well as other regional nations.

Another very important trend in the ASEAN region, indeed in the entire Asia-Pacific region, is the increasing demand for the provision of mobile services including cellular telephony. With a rising GNP per capita, increasing available disposable income, multiple market operators and an increasing telephone line penetration in general, the subscriber base in the Asia-Pacific region for cellular systems is on the increase. In the ASEAN region alone, the subscriber base is already between 50,000 and 100,000 users in Thailand, Singapore, Malaysia and Brunei and rapidly increasing. Within a country, the degree of competition in cellular services to a large extent influences marketing and distribution issues as well as coverage and capacity considerations. With the exception of Singapore, which operates an efficient island-wide cellular system from the sole monopoly telecommunications authority, competition in a liberalized cellular market provides for cheaper equipment and service prices with a higher quality of service.[2]

Mobile telephone services will become an increasing regional as well as international issue as user demands increase in terms of specific market use as well as use of mobile telephones in other locations. Issues of standards and compatibility, access and tariffing for mobile systems will become ASEAN and Asia-Pacific wide regional issues in the near future.

4. COMPETITION AND COOPERATION

Both cooperative and competitive forces are beginning to shape telecommunications developments in the region. An increase in cooperation for telecommunications development is simultaneously taking on a keen competitive side as the various telecommunications authorities of the region begin to flex interests internationally.

International competitive interests are also on the increase in the ASEAN region. Competition in the provision to governments of basic service infrastructure is as keen as markets for sophisticated value-added services. In addition, the trend toward global mergers and alliances of entities with telecommunication concerns spells an even greater strategic positioning of organizations wishing to participate in the markets of Southeast Asia.

With the increasing investment in telecommunications development in each country, private organizations both domestic and foreign are keen to take part. Deregulation of the CPE market in most countries as well as the push toward both privatization of the various telecommunications authorities and an increase in private participation in network and services development means competition for lucrative contracts and various revenue sharing schemes are on the rise. For example, Northern Telecom's UK-based STC Submarine Systems (with an executive office in Singapore), in a joint venture with Thai partner Jasmine International, recently won a $100 million contract from the Telephone Organization of Thailand (TOT) to install an undersea telecommunications network in the Gulf of Thailand. The competitive tender contract was awarded under Thailand's build, operate and transfer scheme and is being financed principally by banks and financial institutions in Thailand.

At the same time that competition for telecommunications markets is increasing, growing cooperation in the ASEAN region and indeed in the entire Asia-Pacific region is evident in the domain of telecommunications development. Such cooperation is acting as a catalyst to change as discussions and activities of the various organizations concerned invariably involve complex issues of management and policy change.

In the area of regional cooperation, several developments are worth noting. With the continual extension of the ASEAN optical fibre cable network (AOFCN) inter-ASEAN and ASEAN regional links to the world are nearing completion. [Details of this network appear in paper number 4.2.3.2 of these Proceedings.] In addition regional network planning, traffic analysis, and management training continues through the efforts of the Asia-Pacific Telecommunity (APT) based in Bangkok. Such organizations and exchanges of ideas can only help to foster a better environment for telecommunications development in the region in the years to come.

One of the most important factors in the development of telecommunications in the ASEAN region is the diversification of user demands. The convergence of computer and telecommunications technologies has resulted in large scale data transfers requiring networks with enhanced functions to meet growing demands of multiple users.

On a less visible but no less important scale, the proliferation of international and regional information networks to and from the ASEAN countries is evident. For example, ASEANET, an electronic trade information network started in late 1991, has been set up to provide business information linked with various Chambers of Commerce and Industry in the ASEAN region. Members will be able to identify trade opportunities in the region via the network. Plans call for ASEANET to link with equivalent networks in the U.S., E.C., Japan and other East Asian countries notably Taiwan, South Korea and Hong Kong.

Another major technological trend affecting the region is the merger of broadcast and telecommunications technologies. The results of this merger are just beginning to shift programing and distribution modes away from the monopoly of the national broadcaster and into the realm of international partners for the diversification of programing.

With the recent launch of Asiasat and the continued regionalization of the Indonesian satellite system, Palapa, many countries are beginning to forge new links through direct lease of transponder capacity. New Zealand TV for example has leased two transponders on Palapa for the delivery of television channels to South East Asia in conjunction with Time-Warner. Agreements are being forged in Singapore (as elsewhere) for downlinking the programmes into the domestic broadcast network through a proposed UHF subscription service and eventually onto a cable television system to be developed jointly by the national broadcaster, SBC, and the telecommunications authority, Singapore Telecom.

Asiasat is also changing the regional telecommunications picture. With the introduction of Star TV from Hong Kong via Asiasat, television programing from that source has a potential audience of over a billion people. Obviously the ability to receive the Star TV signal by viewers in many countries is limited by regulation of TVRO's and/or by costs far beyond the average persons ability to buy reception equipment, limiting for now the size of the actual audience of Star TV.

5. IMPLICATIONS OF REGULATORY EVOLUTION

A common underlying theme to all the diversity in telecommunications development in the region is the need for regulatory policy evolution. The long period of government and monopoly control in many areas of telecommunication is waning in favor of a shift to competitive and cooperative network and service development for a much larger user base. Whether the global drive for changes in the regulatory regime benefits exclusively the larger corporations or can also benefit the smaller user in a low-income country will depend more upon the ability of policy which can eventually reconcile economic gains with wider public interest.

The implications of regulatory changes in the ASEAN countries are being made within the context of the trend toward more open markets for telecommunications systems and services which parallel the general economic trends. The consequence of these cumulative changes has induced a shift in policy from purely quantitative fulfillment of basic telecommunication service to the qualitative improvement of a multiple-source supply of services. The relative importance and influence of Japan, Canada, the U.S. and the European Community in Southeast Asian telecommunications development can be seen in the increasingly keen competition for markets in the region.

In Southeast Asia, the message is clear and gaining an increasingly prominent position in discussions and debates to mandate policy change. A measure of liberalization of markets, regulatory revision and organizational restructuring will help to ensure that telecommunications can fulfill its role in supporting efficient economic and social growth. Whether deregulation and privatization come sooner as in Malaysia or later as may be the case in Thailand and Indonesia, as well as the form of such changes, can only be from the inevitable demand to create networks which eventually provide greater access to meet the needs of users.[3] Regulatory revision, organizational and industrial restructuring, increasing privatization and private participation to include more competitive and cooperative players in telecommunication development are primary in the move to meet a more universal demand.

6. GLOBAL IMPLICATIONS

The dynamic regional economic growth of the ASEAN has put it squarely on the global stage as one of the most important regions for strategic development in the world today. This dynamism is seen in the ever increasing development of telecommunications systems and services throughout the region and in growing network connections globally.

The ASEAN is rapidly becoming a prominent region in the dynamic development of global telecommunications systems. While the promotion of the myth of global networks plays an important symbolic development role in the world today, it is clear that national and to an increasing extent, regional concerns play a far greater role in the development of telecommunications. True global networks, owned and operated by a single entity is simply not a reality despite the exhortations of some such as Cable and Wireless which in mid-1991 completed a network of cables connecting all the continents.[4] The simple fact is no one entity can offer customers their own complete end-to-end full circuits that run across sovereign borders. The fact is that alliances, joint offerings and joint promotions are the make-up of global telecommunications networks in a complex interface of technology, business and regulations.

In essence then, the so-called global network is really an array of global networking comprised of government and private interests across borders to link users with communication needs beyond their own country's boundaries.

In the ASEAN, the growth of local and regional private and public sector telecommunication industries coupled with the expansion of basic infrastructure and enhanced services means that management revision of the state-owned entities and policy revisions are being geared toward meeting new growth potential and meeting ever increasing user demand. The impacts of such regional growth on issues such as tariffing, access and interconnection, gateways, mobile services, satellite systems and by-pass systems as well as needed standardization to meet regional and global integration becomes more pronounced.

What this means for the ASEAN region is a concerted view toward proactive development of the strengths of the national carriers as well as local and foreign participants to the domestic markets. In turn, simultaneous cooperative and competitive focus on the needs of the region as a whole is emphasized. This is part and parcel to overarching economic and political alignment in the midst of the need to connect to a global networking environment. Therein lies the essence of regionalism in telecommunications development. Increasingly, the ASEAN countries are capable of making that development occur in the ways they deem profitable for themselves.

Telecommunications Network Quality and Export Performance

Kara T. Boatman and Joseph F. Francois*
NERA and the University of Maryland;
Research Division, U.S. International Trade Commission

ABSTRACT

In this paper we examine the contribution of national telecommunications infrastructure to export performance in the service and manufacturing sectors of developing countries. We place emphasis on trade in producer services, which are now at the center of the current GATT initiative to liberalize trade in services. We also examine the contribution of network quality to aggregate export performance.

1. INTRODUCTION

In this paper we examine the contribution of national telecommunications infrastructure to export performance in the service and manufacturing sectors of developing countries. The recent literature on trade in services has focused attention on investment restrictions and the need to establish a local presence in service export markets. (See Deardorff, 1985; Feketekuty, 1985; Francois, 1990a; Gibbs, 1985; Hindley, 1988). The role of intermediate services as linkages in the coordination and control of the interdependent elements of complex, modern production processes has also been emphasized. (See Francois, 1990b,c). Because traded services are often information intensive, the ability to engage in cross-border service transactions depends critically on available telecommunications facilities in the partner countries. In this paper, we analyze, empirically, the role of national telecommunications infrastructure in this process. We place emphasis on producer services, which are now at the center of the GATT initiative to liberalize trade in services. We also examine the contribution of network quality to export performance in the manufacturing sector.

The results presented here indicate that telecommunications network quality is an important determinant of the pattern of trade in both goods and services. This is consistent with the observation that trade in services often involves cross-border transmission of information, and with the observation that such information flows are also an important aspect of global integration of manufacturing. Our results thus lend support to the notion that the development and modernization of the service sector in third world countries and Eastern Europe, in particular their integration into the global economy, depends on upgrading their underlying telecommunications infrastructure. We also offer evidence that the ability of developing countries to export manufactures can be constrained by their underlying telecommunications infrastructure.

2. BACKGROUND

Telecommunications provides a critical cross-border linkage between producers and their overseas markets. For this reason, a high quality telecommunications system can enhance a country's export performance in a number of ways. Telecommunications linkages may promote exports by facilitating entry into non-traditional export markets. Such linkages facilitate the adoption of increasingly complex production processes and may thus make possible the transition to more sophisticated and more valuable manufactured exports. In this context, a good telecommunications system may also help to attract exporting multinational corporations and encourage the integration of local firms into globally integrated industries.

Additionally, today's "smarter" telecommunications equipment not only transmits information; it can also process it. This capability may allow a country to export a variety of services in addition to traditional manufacturing and primary exports. As an example, Singapore's sophisticated telecommunications system has played an important role in that country's regional dominance of financial services exports.[1] Therefore, as domestic income levels rise and a country's advantage in traditional exports erodes, a well-run telecommunications system may facilitate a transition to "high-tech" manufacturing exports and, ultimately, to service exports.

source: Office of Technology Assessment (1991, p.43).

Because traded services are relatively information intensive, the availability and cost of telecommunications linkages is likely to be

particularly important for international service transactions. This is because services, unlike goods, are consumed as they are produced. This characteristic of service transactions often requires a direct interaction between user and provider. Because of this need for interaction, it may be necessary for the provider of services to establish a presence in the importing country. Once a local market presence is established, services are then traded through the local establishment. As a result, while actual trade involves the cross-border movement of information, equipment, and personnel, the final "traded" service includes a bundle of services that have been both traded and produced locally. Telecommunications network quality can facilitate the interaction between user and provider, and may reduce the extent to which a local presence is required.

Table 1 presents measures of the relative importance, in revenue terms, of local market activities (reported as foreign direct investment or FDI revenue) and the cross-border movement of information, equipment, and personnel, for the foreign service transactions of U.S. providers. It can be seen that while local market activities and cross-border information and factor flows are both important factors in services trade, this varies significantly by service type. For services that are information intensive, such as information services, management/consulting, and engineering, we expect the quality and availability of telecommunications links to have an important effect on the pattern of trade in services.

3. THE BASIC APPROACH AND DATA

It is important to distinguish between domestic and international telecommunications networks. Although a sophisticated international telecommunications network currently links most countries in the world,[2] it is of little value to individual firms in exporting countries unless their domestic systems are also adequate. An international call must not only be transmitted across borders, but it must reach its party within the destination country. A domestic telecommunications "bottleneck" substantially decreases the value of the international network to inbound and outbound callers alike. The analysis presented here treats the international portion of the telecommunications network as exogenous and constant. We focus on the quality of the network as a positive influence on export performance.

It is also important to understand the relationship between telecommunications equipment and telecommunications services. The quality of a country's telecommunications system must ultimately be assessed in terms of the quality of service provided to its customers. However, the ability to obtain a dial tone, the speed with which a call can be completed and the ability to simultaneously transmit data and voice messages all depend on the type of equipment in the network. Therefore, the quality of the equipment corresponds directly to the quality of service; although measures of equipment quality are used in this paper, they are in fact measures of service quality as well.

The quality of a country's telecommunications system can be measured in a number of ways. It is important, however, that such measures capture both access to telecommunications services and the degree of modernization inherent in those services. Expressed differently, a model should reflect both the quantity and quality of telecommunications services.

In this paper, we rely on two measures of network characteristics: (i) lines using electronic switching (ESS), and (ii) number of telephone access lines per 100 population (density). ESS is a quality variable that measures the number of access lines which use solid-state switching devices and computer-like operations to complete calls. The density variable is the most common measure of telecommunications availability.

Since producer services such as management consulting and data processing are information-intensive, and since telecommunications services facilitate the transfer of information, it follows that a country's ability to export services like these are likely to be influenced by the quality of its telecommunications system. However, this relationship is extremely difficult to test empirically. Accurate service trade data are notoriously difficult to obtain, since service exports have traditionally been calculated as a residual in national accounts data. However, service trade data for the U.S. and selected trading partners have been compiled for 1986 and later years. Although these data are by no means complete, they do permit a crude test of the relationship between telecommunications and developing country service exports.

We focus our attention on developing countries. Our sample on trade in services includes 13 countries, while the sample for exports of manufactured goods includes 43 countries.[3] Our data on trade in services are drawn from the Bureau of Economic Analysis' benchmark survey. The benchmark survey covers U.S. exports and imports with 28 countries in 1986 for eleven service sectors. Revisions to this data were published in June 1989 and September 1990 (see Krueger 1989 and DiLullo and Wichard 1990). Utilizing data on U.S. bilateral service flows, we analyze the composition and volume of U.S. trade in services, assessing the role of information intensity and telecommunications network quality in determining the pattern of trade in services.

Aggregate data on exports for each country are from the International Monetary Fund's Direction of Trade Statistics Yearbook. In addition to measures of telecommunications network characteristics, we also expect export performance to depend on income levels and relative country size.[4] Data on population, GDP, and other macroeconomic indicators are from the World Bank's World Development Report. Commodity trade data (on an SITC basis) are from the United Nations.

4. THE RESULTS: SERVICES

While the literature on trade in services has emphasized investment restrictions, the results presented here highlight the role of available telecommunications linkages. Because traded services are often information intensive, the ability to engage in cross-border service transactions depends critically on available telecommunications linkages.

To formally assess this relationship, we have run regressions on 1986 telecommunications and service trade data using the following functional form:

$$\text{Exports} = a_0 + a_1(\text{Density}) + a_2(\text{ESS}) + a_3(\text{Pop}) + a_4(\text{PCY})$$

Soi

where Density and ESS are defined above, Pop is total population, and PCY is per-capita GDP. The dependent variable represents one of the following per-capita export categories: total service exports, "other total" service exports,[5] management consulting and public relations, mining services, advertising and "other" service exports.[6] While there were several additional service categories for which trade with the U.S. was reported in the benchmark survey, the available sample for developing countries was insufficient for any meaningful analysis.[7]

Regressions were run for all service categories for which there were at least 10 observations. An exception was made in the case of "other total" service exports; although there were only 7 observations, this category was judged to be important to the analysis. Consequently, correlation analysis was performed. All results are reported in Table 2.[8]

The results in Table 2 indicate that density and ESS switching are both positive and significant influences on total per capita service exports to the U.S., as well as on per capita exports of mining services. In addition, telecommunications quality appears to play

Table 2

t-ratios are reported in parentheses. F-statistics for the full model are reported in the R^2 column.

a role in explaining exports of management consulting and public relations services, and to have some impact on exports of advertising services. However, the results for the category of "other services" were inconclusive. Correlation analysis between per capita exports of telecommunications-exclusive services and telecommunications network quality yielded strong results as well. Correlation coefficients of .93 and .78 were generated for density and ESS switching, respectively.

To assess the individual influence of telecommunications density and ESS switching on service exports, F statistics for each telecommunications variable are also reported. These are based on partial sums of squares. Telecommunications density contributes significantly to the explanatory power of the empirical model. However, ESS switching does not appear to play as important a role in explaining total service exports. ESS switching is significant for the remaining categories.

The F statistics indicate that both telecommunications density and ESS switching contribute significantly to the explanatory power of the empirical model. The exception is the category of total service exports, where ESS does not contribute significant explanatory power. While the level of significance is quite low in most cases, this may be due to the small sample size.

5. THE RESULTS: TOTAL EXPORTS

Regressions were run using 1986 data for telecommunications and aggregate exports. The same functional form is used as in the analysis of services. Exports are again measure on a per-capita basis. Results are reported in Table 3 for 1986 for our sample of developing countries. The coefficients on both telecommunications density and ESS switching are significant, and have the expected sign. The coefficient on population is negatively signed in both runs, as expected. The coefficient on per-capita income is positively signed, also as expected.

The results suggest that, in the context of the developing countries in our sample, an increase of .01 lines per-capita would yield an increase in exports of $61 per-capita. Similarly, an increase of 5000 ESS switched lines generates an additional $1 of export revenue per person. It is important to note

Table 3

Regression Results:
Per-Capita Total Exports, 1986

	a_0	a_1	a_2	a_3	a_4	Adj. R^2	n

t-ratios are reported in parentheses. F-statistics for the full model are reported in the R^2 column.

that while the incremental contribution of additional investment in telecommunications infrastructure to export revenues may appear to be quite small, these investments typically occur in large increments.

To assess the individual influence of telecommunications density and ESS switching on aggregate exports, F statistics for each telecommunications variable are also reported, based on partial sums of squares of the error terms. Telecommunications density is a significant explanatory variable for LDC exports. The ESS switching variable is also significant. The F statistics indicate that both telecommunications density and ESS switching contribute significantly to the explanatory power of the empirical model. The contribution of the ESS variable is significant at the 99.5% level.

6. THE RESULTS: HIGH TECHNOLOGY MANUFACTURES

While the results described in Section 5 suggest that telecommunications quality influences export performance, it is unlikely that network quality influences all exports equally. Because telecommunications is postulated to generate greater benefits as production processes become more complex, a strong relationship between network quality and exports of high technology products was expected. Regressions were run using 1986 data for various 4-digit categories of manufactured exports. We continue to use the functional form described in Section 4. Selected results are presented in Table 4.

Table 4

Regression Results:

Accounting machines, computers	-1.78	1.78E-05	.15	-8.47E-03	-3.08	.83	21
	(-1.28)	(3.83)	(1.22)	(-.27)	(-.06)		
F		1.8	14.4			9.40	
(pr > F)		(.25)	(.005)			(.025)	
Aircraft engines	-3.70	1.04E-05	.18	1.17E-02	1.23E-03	.62	20
	(-2.30)	(2.14)	(1.30)	(.89)	(2.00)		
F		6.0	7.5			8.78	
(pr > F)		(.05)	(.025)			(.025)	

As the results above indicate, ESS switching consistently contributes significantly to the explanatory power of the model. Telecommunications density also contributes to the model's explanatory power, but often at a lower level of significance.

7. CONCLUSIONS

In this paper, we have examined the relationship of telecommunications infrastructure to trade in intermediate or producer services. We have also examined the contribution of network quality to export performance in the manufacturing sector. Our results indicate that telecommunications network quality is a significant determinant of the pattern of trade in goods and services.

The quality of telecommunications services does appear to play a role in explaining service export performance across developing countries. However, the paucity of the data makes it difficult to determine whether exports of certain services are more heavily influenced by telecommunications than others. In addition, it is important to note that these data exclude transactions between multinational corporations. Thus the hypothesis that telecommunications facilitates the transfer of headquarters services from parent to subsidiary cannot be tested here. Moreover, these data do not reflect service trade between developing countries or between LDCs and other industrialized countries, but only their comparative advantage in exporting to the U.S.

Telecommunications network quality also appears to influence exports of certain manufactured products. In particular, density and ESS switching emerge as significant influences on exports of high technology manufactured products and producer intermediate goods. Our results suggest that telecommunications quality may play an important role in the ability of Asian exporters like Hong Kong and Singapore to enjoy a comparative advantage in exports of high technology manufactures.

Our results suggest that the contribution of national telecommunications infrastructure to developing country export performance should be considered in telecommunications policy decisions.

NOTES

*This paper represents the opinions of the authors, and is not meant to represent the opinions of the ITC or any of it members.

1. See Motiwalla (1988).

2. The international network is comprised largely of undersea cable as well as communications satellites launched by private firms in the U.S. and other industrialized countries.

3. The list of countries in the services sample include: Argentina, Brazil, Venezuela, Saudi Arabia, Hong Kong, Indonesia, Malaysia, Philippines, Singapore, South Africa, Israel, Mexico and India. The list of countries in the manufactured exports sample included: Ethiopia, Kenya, Liberia, Madagascar, Malawi, Morocco, Senegal, Sierra Leone, South Africa, Sudan, Tanzania, Zambia, Hong Kong, Indonesia, Korea, Malaysia, Pakistan, Papua New Guinea, Philippines, Singapore, Thailand, Greece, Hungary, Portugal, Turkey, Yugoslavia, Israel, Oman, Saudi Arabia, United Arab Emirates, Argentina, Bolivia, Brazil, Chile, Colombia, Costa Rica, Dominican Republic, El Salvador, Guatemala, Honduras, Mexico, Nicaragua, Panama, Paraguay, Peru, Trinidad and Tobago, Uruguay and Venezuela.

4. In the empirical trade literature, models of this type are known as gravity models. The recent theoretical literature on trade with product differentiation and imperfect competition provides a theoretical basis for expecting this relationship between trade, income levels, and relative country size. (Helpman and Krugman, 1985).

5. "other total" represents total service exports less telecommunications service exports.

6. "other" service exports include agricultural, health management, accounting, educational, mailing and reproduction, personnel supply, and sports and performing arts.

7. These categories included: computer and data processing, database and information services, R&D and testing, legal services, industrial engineering, industrial maintenance and repair, and primary insurance. These categories contained either exclusively "0" observations for developing countries, or so few positive observations that the analysis was meaningless.

8. Highly suggestive, suggestive and poor results are reported together in Table 10. Note that the density and ESS coefficients reported for "other total" service exports represent correlation results, not regression results.

Telecommunications Standards and Asia/Pacific Trade

Eugene B. Lotochinski
Vice President, Marketing & Business Development
Northern Telecom Asia/Pacific
Tokyo, Japan

Abstract

One essential infrastructure needed for the advancement of trade in the Asia/Pacific region is telecommunications. Telecommunications networks rely on use of global, regional and national standards for their implementation. It is significant that there is no regional telecommunications standards body in the Asia/Pacific region equivalent to those in Europe or North America.

Inherent in the telecommunications business is the matter of standards. Standards represent specifications for a wide variety of different technical details: the way different pieces of equipment will operate; how they will interconnect with each other; how the frequency spectrum will be used; how electronic messages between different systems will be formatted; how billing information will be collected and formatted; how signals will be encoded or multiplexed; what transmission levels are acceptable; etc. In fact, almost every facet of telecommunications networks are or can be covered by standards.

Some examples of standards are the basic Pulse Code Modulation (PCM) standard for digital voice; the sophisticated CCITT Signaling System Number 7; and the standards related to the Integrated Services Digital Network.

Standards are the enablers for the interconnection of telecommunication networks. This interconnection is what allows the free flow of information which today is fundamental for international trade. It is not an exaggeration to say that the volume of trade today would be impossible to support without excellent national, regional and global telecommunications.

Therefore, it is fair to say that telecommunication standards have played a tremendous role in the development of the world economy today.

If one were to start with a completely blank slate concerning a telecommunications network, it would be possible to develop all specifications for such a network with no reference at all to any other specifications or standards.

One could establish a different encoding scheme for digital voice. One could develop a completely new and different signaling scheme for establishing connections between different switching systems in the network. One could even decide to use a broader or narrower bandwidth or bit rate for the messages to be carried on the network.

Such a self-contained network could then be built to these new and different specifications, and it probably could provide good telecommunications service, although much testing and debugging would undoubtedly be needed.

However, when the owner of a network built to such completely new and different specifications attempted to interconnect this network to other networks, problems of incompatibility would arise. As a minimum, there would need to be all manner of converters to adapt the interfaces between the networks. In the worst case, communications might be so degraded as to be impossible.

The reality, of course, is that network operators do not generate all new specifications covering all technical matters related to their networks. From the perspective of the network owner, the cost of developing and verifying all technical specifications would be extremely high. From the perspective of equipment manufacturers, it would be extremely costly to have to produce equipment to a wide and unpredictable range of specifications.

Instead, network operators use a combination of accepted international standards together with suitable local specifications to define their network requirements. This permits equipment manufacturers to manufacture a smaller range of equipment, thus keeping the price down.

The standards which have emerged today are the result of a complicated process involving telecommunications users, telecommunication carriers and administrations, and telecommunication equipment suppliers. There is discussion, debate, disagreement and finally, compromise. The ultimate objective is to maximize, to the extent possible, the benefits of each specific standard to all the players.

The benefits of telecommunication standards to users includes lower prices, better quality and ubiquitous service. The benefit of telecommunication standards to carriers and administrations include simpler design of networks; better quality and lower priced products due to supplier competition; and much simpler interconnection with other carriers and administrations. Suppliers of telecommunications equipment benefit from being able to address a much larger market with their products, and reduced cost of research and development to adapt their products to different markets.

Messaging Handling Systems provide an excellent example of the way in which all players benefit from standards. Thirteen years ago, many proprietary text messaging systems had been developed, and almost none of them could talk to each other. This presented a fragmented market too small for most suppliers to address efficiently and did not represent a good business for them. Users were frustrated with their inability to communicate with other users. And carriers could not get quality products to offer the service. With the adoption of the 1984 and 1988 versions of the CCITT X.400 series of Message Handling recommendations, a global market for text messaging is rapidly emerging.

As it happens, standards in telecommunications are established at three distinct levels--global, regional and national.

Organizations such as ISO, CCITT, and the IEEE develop global recommendations which are used throughout the world. At this level, the setting of standards can become a highly political process. For example, some nations have accused other nations of using standards as a non-tariff trade barrier.

Because of such political considerations, and because full agreement among all interested parties on a voluntary basis is difficult to achieve, global standards often contain a large number of permitted variations or options. While the options are required politically, they slow the development of products, since manufacturers must wait for each network operator to reach a decision on which options will be included in his particular network.

To address this issue, regional standards organizations have emerged to allow groups of countries to make the choices of options among a smaller number of players. This also allows the groups of countries to develop a regional position, and thus have a single strong bargaining voice in CCITT and other global

standards forums. This process provides hard standards which suppliers know will be frozen for a sufficient time to allow them to get a reasonable return on investment in development of new products.

Two major regional standards bodies include the European Telecommunications Standards Institute (ETSI) and the Exchange Carriers Standards Association (ECSA), which are rapidly agreeing upon European and North American telecommunication standards. The resources of these regional groups include some paid workers and a much larger number of volunteers, e.g. from telecommunications suppliers, to speed the process.

The ultimate results of this regional standards work will be telecommunications network offerings in these regions which will offer advanced capabilities on a seamless basis across various networks.

It is significant that there is no regional body in the Asia/Pacific region equivalent to ETSI or ECSA.

Economic growth forecasts for Asia/Pacific are very optimistic. And major economic growth will clearly require major growth in telecommunications as a basic infrastructure supporting business of all kinds.

But, without well-defined and agreed to regional standards, telecommunication networks in Asia/Pacific countries will continue to be fragmented, with individual countries and individual network operators using a wide mixture of various global, regional and/or national standards. To some extent, this results in de facto standards to be used which may or may not be in the best interest of a given country or of the entire region.

A well defined set of standards, tailored to the Asian business environment will foster cooperation, and improve productivity throughout the region. Users and nations will benefit since it will be simpler to offer new advanced services across multiple networks. Such standards will make it easier for telecommunication equipment suppliers to develop products tailored to the Asia/Pacific market, by enabling them to address this market as a group, instead of having to adapt products to the large number of national variations which currently exist in the region.

Regional standards will also encourage development of a wider range of Asian products. Because of the larger market which will emerge across Asia, products which are currently not feasible, because of a limited market, will become more attractive. And the process of developing regional standards will include development of well defined interfaces to allow interworking with the North American and European standards, which will benefit all the stakeholders.

It should also be recognized that the CCITT has set forth proposals to regionalize or decentralize standards setting. This will only work in Asia/Pacific if there is a regional standards setting body.

It is strongly suggested now is the time for the Asia/Pacific region to begin developing its own standards harmonization program.

RELATIONSHIPS BETWEEN JAPAN, EUROPE AND THE USA

BRINGING UNIVERSAL ISDN SERVICE TO REALITY !

Dale T. Rogers, AT&T Network Systems
Jerry Nowicki, ESI Systems, Int'l.
Takeshi Kawauchi, NTT
Osamu Inoue, NTT

1.0 ABSTRACT

Integrated Services Digital Network (ISDN) applications have now spread through out much of the industrialized world, though not as rapidly as the telecommunications industry had originally expected. However, last year several equipment and service providers in the U.S. and other countries began to actively partner with each other to proactively expand international ISDN service. In response to multinational customers, these providers pooled their resources and developed a series of Basic Rate (BRI) ISDN applications demonstrations. This then led to collaboration to provision ISDN applications for several new commercial customers between the U.S. and Japan.

While such cooperative efforts are truly noteworthy, they are only the beginning. Building upon these successes, the cooperation must continue and it is now time for the industry to do more to assure that ***ISDN services become UNIVERSALLY available***. Telecommunication service and equipment providers must now make a concerted effort, both individually and as an industry to completely topple the remaining technical, regulatory, financial and educational barriers that hold back the deployment of ***UNIVERSAL ISDN***. Today, more than ever, there is a need to shift from informal industry coopetation to stronger and more committed partnerships in order to forge the proper ISDN application sets for specific customers and industries. (1)

2.0 GLOBAL ISDN ENVIRONMENT

UNIVERSAL ISDN services have certainly been the vision of the telecommunications industry since the concept was formulated by CCITT many years ago. Since that time, those who believe in, and have participated in this vision have experienced both the initial euphoria surrounding this next generation "technological revolution" and the reality of implementing this "standardized" vision. However, recently the telecommunications industry has entered a new more "customer focused" phase. This more mature phase, which blends futuristic vision with technological and human factor realities to achieve actual customer application needs, is proving to be the right formula for success.

What does success mean? Well, probably not 100% deployment and usage throughout the industrialized world as once envisioned. This view is unrealistic in todays world of vast technological choices and competitive service market place. ***However, ISDN will be a dominant factor in the now rapidly emerging world of public switched data and data related communications***. After several years of evolving this new integrated type of technology, the industry is realizing that if it can match its available technology with customers communication needs, then ISDN will easily fulfill the rapidly growing market needs for world wide integrated data communications via the public switched network. Recent industry studies project over 4.5 million ISDN equivalent lines by 1995 (figure 1). In Europe, the

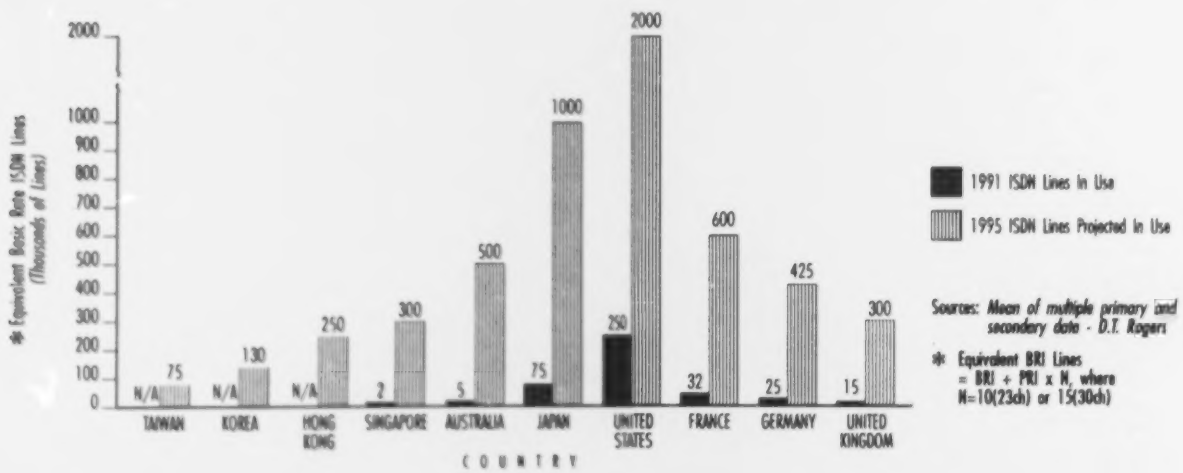

Figure 1
Global ISDN Line In Use - Selected Countries

ISDN market is expected to take a firm hold during the 1993-96 time frame and projected to capture as much as 22% of the data connection traffic in Western Europe. (2) The growing interest in image and videoconferencing applications will further expand the use of integrated data at an even more rapid rate. For instance, a PictureTel Corporation spokesperson projects that Basic Rate (BRI) ISDN will essentially capture as much as 90% of the low-band-width (56kbs - 128kbs) videoconferencing market by 1995. (3)

Integrated data ISDN applications are especially suited for small and medium business markets as well as residental work at home applications which have been previously limited to communicating via low speed modems over the existing analog switched public networks. ISDN is particularly attractive for these customers since it provides ease of access and use, and lower overall costs. This represents a sensible alternative for this huge customer base as compared to the costly dedicated private network solution. The strong customer interest in dial-up ISDN video conferencing today and the subsequent price/value advances being made are one area that customers are going to benefit. Additionally, the experience that the industry has gained by the successful implementation of N-ISDN service applications is proving to be invaluable to the growing number of industry players as they begin to plan for the next stage of ISDN, --- broad band service. Experience shows that while theoretically it may be possible to leapfrog from one technology to the next, in practicality it is almost impossible due to various economical, regulatory, and just plain sociological human factor considerations.

Some of the key factors that now contribute to the ability of ISDN to meet many customer needs are;

- Widespread ISDN switch availability,
- Circuit and packet switched network connectivity,
- Increased choices of affordable CPE,
- Realistic and affordable tariffs,
- Informal industry partnerships,
- PTT marketing and ISDN sales incentives,
- Increasingly sophisticated customer base,
- Decentralization of major corporations and public infrastructures.

Once these basic factors are addressed by the respective parties, there is a high confidence level that the PTT's customer growth rates will be in the range of 200 -300% per year for the first few years, attaining approximately a 1 - 3% penetration of the total customer base. Much further market penetration is expected as customers become more comfortable and familiar with lower cost tariffed ISDN services for integrated data applications. For example, NTT expects that 20 - 30% of their business customers will be using ISDN by 1996.

Critical to the marketing successes though is the importance and availability of low cost and easy to use customer premise equipment (CPE) which is now readily apparent as part of the ISDN equation. Japanese manufacturers recognizing this huge potential market have now created over 200 models of ISDN CPE with prices planned to start as low as Y29,800 (~$225 US) for the yet untapped residential market. In the U.S., manufacturers are also beginning to provide many ISDN CPE options to end customers. A recent edition of Network World noted at least 50 different models available in the U.S. mainly targeted for data and business usage (4).

3.0 U.S. - JAPAN COOPERATION

In 1989, AT&T, Nippon Telegraph & Telephone (NTT), Pacific Bell and Kokusai Denshin Denwa (KDD) established a long-term partnership to provide ISDN services for mutual customers in Japan and California. (5) The initial ***focus*** of the relationship was not on the partnership itself, but rather ***on the customers***. Thus, the set of customer needs became the major subject of discussion and subsequent work plan. It was clear from the beginning that the technological, regulatory, investment and marketing issues would be influenced greatly by the kinds of applications that multinational customers wanted.

A process was proposed by NTT which outlined a phased approach to meet the customer needs, while evaluating each steps success along the way.

- X DAY - ISDN application end-to-end network testing, tariff effective
- Y DAY - end to end customer demonstrations and, initial customer offerings
- Z DAY - joint expansion of commercial service

This approach gave all the parties ample time to address the respective barriers they needed to overcome in order to assure a successful process. Since agreement and execution on the process was successfully accomplished, further progress is now being focused on future applications, sharing of target customers, and cooperative marketing initiatives.

The next steps in the process are to utilize the model to expand the cooperation between other U.S. local exchange carriers (LEC's) and Japan. For instance, an agreement has now been reached between NTT and BellSouth to support ISDN services through AT&T and its correspondent KDD, between their respective customers. Preparations were recently completed in November, 1991, to offer the first commercial ISDN service applications between customer locations in Japan and Atlanta, Georgia. Future plans include expanding the NTT and AT&T relationship to all of the U.S. LEC's based on their interest in supporting multinational customer needs. (6) Similarly, partnership efforts are being developed with ISDN-ready PTT's within the Pacific Rim and Europe. One example of California customer benefiting from this concept is Meridian Systems, San Jose, Ca. Their worldwide multimedia conferencing ISDN network is depicted in figure 2.

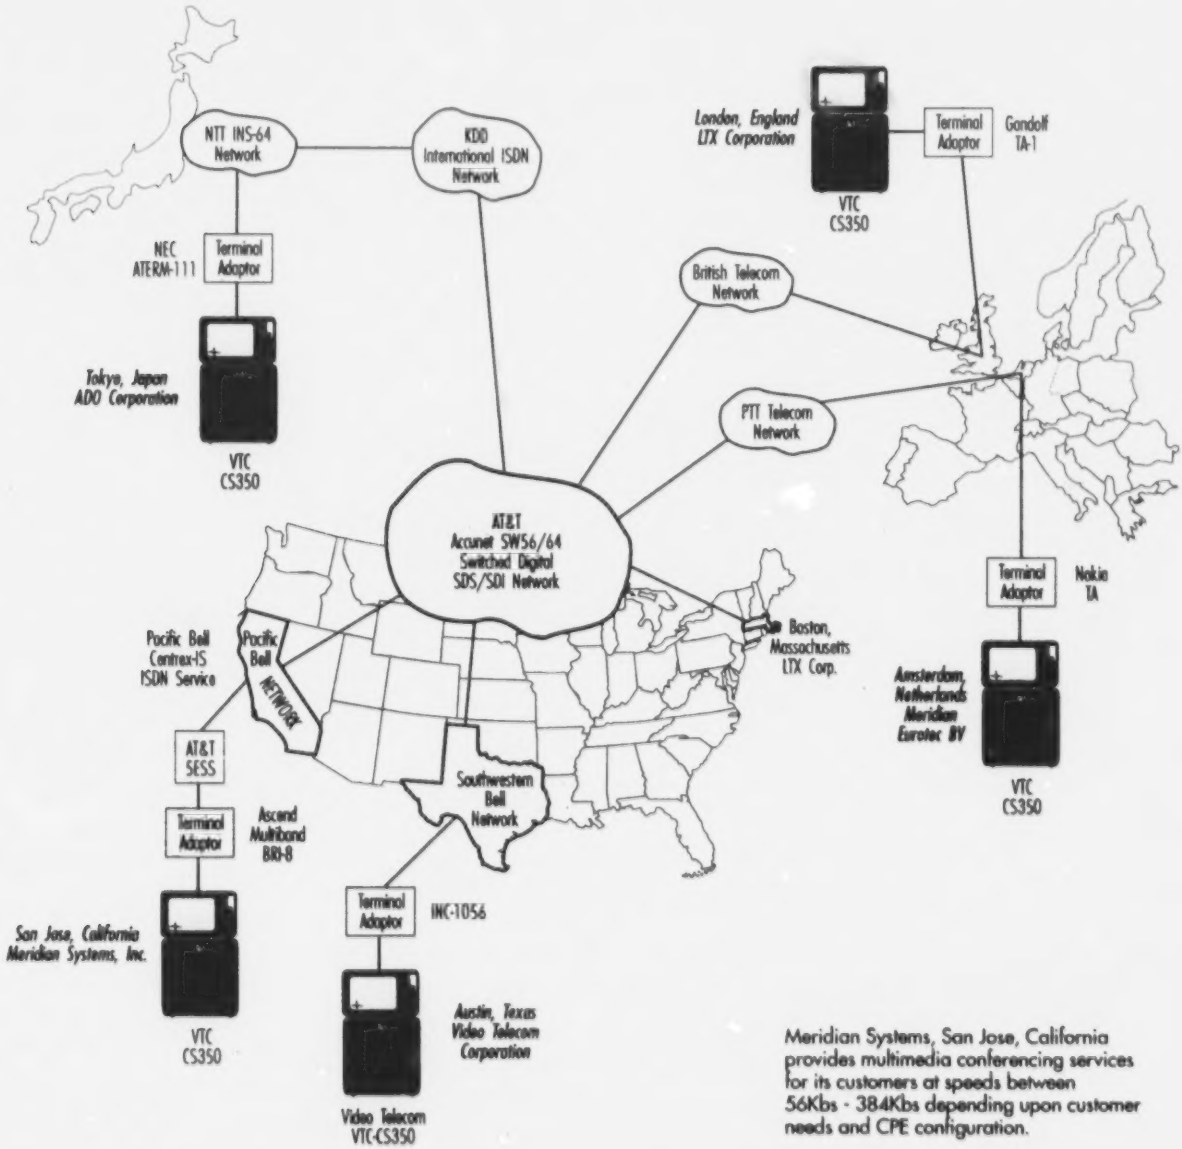

Figure 2
Meridian Systems ISDN Network

887

As a commitment to the concept of ***UNIVERSAL ISDN***, AT&T has put a team in place to facilitate the formulation of partnerships which will support additional international customers who want publicly accessed ISDN services. Notably, NTT has successfully achieved agreements with British Telecom, France Telecom, Deutsche Bundespost. These agreements establish specific ISDN applications and the respective manufacturers which will support customers in these locations. This activity combined with the ***NATIONAL ISDN*** efforts being launched in the U.S. will bring us closer to Universal ISDN services. (7, 8)

4.0 CONSTRUCTIVE PARTNERSHIPS

There are some individuals and organizations in our industry who believe that industry cooperation is all that is needed to assure successful deployment of ISDN or any other new technology. However, our experience suggests that the cooperation is not enough. Constructive partnerships wherein each partner's self interests are safeguarded appear to be the best solution. The most obvious benefit comes from the learning achieved by partners in terms of their differing approaches to their respective customer sets. Given the various options available to build applications, the partners can then focus on the critical elements needed to achieve the best price performance. These elements include:

- Network connectivity
- Terminal interoperability
- Terminal pricing
- Customer needs

One of the keys to success is to develop agreements on ways to optimize the applications for the benefit of all. This is truly when the customers receive the most benefit. The partnerships become the catalyst or change agent for resolving many of the critical elements needed for success. Once resolved, ISDN applications then become user friendly and properly positioned to meet pent up demand.

For example, to assist partners in addressing customer needs between California and Japan, an ever growing universal application set can be easily referenced by respective sales account executives to meet their customers needs (figure 3). In addition, sales brochures have been developed which

JAPAN ⟷ CALIFORNIA

	AVAILABILITY / COMPATIBILITY			
APPLICATION	NTT	KDD	PACIFIC BELL	AT&T
Video - Conferencing 112/128 Kbs	Y	Y	Y	Y
G4 Facsimile	Y	Y	Y	Y

Floppy Disc Transfer	Y	Y	*	Y

Y = Tested
* = Not Tested Yet

Figure 3
Global ISDN Application Compatability

provide meaningful information about how an application works, the benefits, and the initial start up costs (figure 4). NTT has developed similar sales material (figure 5) and has built a comprehensive list of the ISDN applications that are supported through their partnering arrangements. This ready referenced applications guide includes a list of terminals by all known manufacturer that readily connect to NTT's ISDN service in Japan. All of these efforts are designed to make it easier for customers to take advantage of locally accessed public switched ISDN applications.

Figure 4
Pacific Bell
ISDN Application Salesware

5.0 PACIFIC RIM VISION

There are many people inside and outside this industry that see the 21st century as the "Age of Telecommunications". This is primarily driven by what Haruo Yamaguchi, Chairman of NTT, describes in his recent book as, "kōdō jōhōka", which essentially means, the ***steady rise in the degree of informatization***. (9) Obviously, ***UNIVERSAL ISDN*** will play an important part in this new telecommunications era and the Pacific Rim is moving rapidly to bring the vision to reality. Perhaps the most important factors to assure this goal are the following.

- Widespread public acceptance
- Industry, customer involvement
- Building broad based applications

One of the major drivers in gaining widespread public acceptance is to assure that ISDN is easy to order and easy to use. The second but just as important driver, is to keep public access inexpensive. This translates not only into inexpensively tariffed access rates but also reasonably priced customer terminal equipment. The Pacific Rim industry players can assume an important leadership role in influencing this direction.

The customer-industry involvement is best described as tightening the linkage between customers and industry players in industry sponsored forums to assure that customer needs are well understood and that agreement can be reached on how these needs can be addressed.

Lastly, building broad based applications simply means that services need to be designed which not only benefit businesses but also enrich our every day lives. In the future, society will require a balance of the needs for material goods and services with the intrinsic values of family and mental well being. This is clearly the challenge for the 21st century and the Pacific Rim can play an important part in bringing this vision to reality.

NTT's ISDN "INS-Net" and Customer interest in Global ISDN

Naoki Takeda, Senior Manager
ISDN Development and Promotion Department
NIPPON TELEGRAPH AND TELEPHONE CORPORATION (NTT)
Tokyo, Japan

1 ABSTRACT

ISDN is the wave of the future. It will revolutionize the field of communication as we now know it, starting in the workplace and then following with changes at all levels of society. The result will be a dramatic reduction in the time required to communicate all types of information as well as an increase in applications impossible with conventional technology. In short, ISDN is a tremendous innovation that promises to bring about immense changes in our work, lifestyles and society.

Internationalization is already sweeping the globe, expanding the movements of people and goods. Economic coalitions are superceding national boundaries; nations are becoming more and more interdependent. Only by working together in a worldwide effort will we be able to solve our most pressing problems. But in order to work together effectively, nations must consider not only what is best for themselves but for the world as a whole.

Technology is the driving force behind globalization, and the role of telecommunications has been particularly great. Yet just as telecommunications encourage globalization, globalization itself fosters the need for a standard, worldwide communications system.

ISDN is destined to play a major role in linking the world in the forthcoming "Era of Globalization".

Today, customers' needs are going beyond the nationwide availability of NTT's ISDN services, "INS-Net", in Japan. Customers' needs to use ISDN worldwide are increasing day by day because of its cost effectiveness and new value-added applications.
In order to cultivate customers'needs for global ISDN, NTT has been making efforts to make them realize the advantages of global ISDN especially by demonstrating some actual applications of global ISDN between Japan and several other countries in the exhibit "NTT collection'90". The demonstration attracted a lot of of visitors and they showed keen interests in global ISDN. Moved by the demonstration, many visitors, who had had no chance to experience global ISDN directly, made a decision to introduce INS-Net to utilize global ISDN.

Today, INS-Net customers can take advantage of ISDN service between Japan and and 11 other countries such as the U.S.,U.K. and France. There are some barriers based on the technical differences among each country's ISDN. For instance, it is not so easy to utilize the ISDN interconnection between Japan and the U.S. because of the difference in the transmission speed of ISDN between two countries. In order to promote global ISDN at least, these problems have to be solved.

NTT believes that to promote global ISDN helps not only promote INS-Net in Japan but also promote ISDN service in every other country. NTT hopes that the day will come soon when peoples all over the world are connected by ISDN.

(2) EXPANSION OF SERVICE AREAS

By the end of March 1992, service areas will be expanded to about 2,120, including more than 95% of the nation's cities. (Figure 7)

INS-Net Service Area

(Oct. 1991)

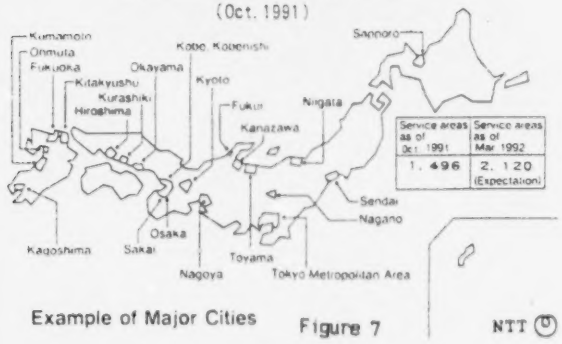

Figure 7

3 PRESENT STATUS OF GLOBAL ISDN

With the globalization of economy, the means of global telecommunication has become one of the most important factor in corporate management. And INS-Net customers' needs to use ISDN between Japan and overseas countries have rose day by day. In this situation, interconnection of ISDN between Japan and overseas countries has progressed under the collabolation of telecommunication carriers in the world.

INS-Net was linked with KDD (Japan's international common carrier) in October 1989, making commercial international ISDN services available for the first time. KDD's commercial international ISDN services now connect Japan with 11 other countries including the U.S., the U.K., France, Singapore, Australia, Italy, Germany, Hong Kong, and Belgium etc. So, today, INS-Net customers can take advantage of ISDN service between Japan and 11 other countries. (Figure 8)

4 BARRIERS TO GLOBAL ISDN

Although more and more countries are being connected to NTT's INS-Net over ISDN links, there are still some barriers that stand in the way of further global penetration.

As the number of global ISDN customers has increased, so has the demand for diversified applications. But so far, due to the limited range of global ISDN compatible terminal equipment, applications are largely confined to G4 facsimile transmission and video conferencing. There is also a barrier based on the technical defferences among each country's ISDN that hinder further penetration, such as the difference in the transmission speed of ISDN between Japan and the U.S. (the transmission speed ISDN in Japan is 64kb/s, while that in the U.S. is 56kb/s). This forces customers to obtain terminals with the extra functional capability to adjust between speeds.

To break through such a situation, NTT has made every effort. One of its efforts was holding presentation of applications for global ISDN demonstration at the "NTT collection'90" exhibit.

5 PRESENTATION OF GLOBAL ISDN AT "NTT COLLECTION '90"

5.1 SUMMARY

Today, INS-Net customers' needs to use ISDN worldwide are increasing day by day because of its cost effetiveness and new value-added applications. In order to cultivate customers' needs for global ISDN, NTT has been making efforts to make them realize the advantages of global ISDN, especially by demonstrating some actual applications of global ISDN between Japan and several other countries at the "NTT collection '90" exhibit. The demonstration attracted a lot of visitors and they showed keen interests in global ISDN. Moved by the demonstration, many visitors, who had no chance to experience global ISDN directly, resolved to introduce INS-Net so they could take advantage of global ISDN.

Here NTT presents its experience of the global ISDN demonstration at "NTT Collection '90", hoping that it will be helpful for the execution of "TRIP '92", the demonstration for promoting the National ISDN 1 (NISDN1) in the U.S.

5.2 "NTT COLLECTION"

The "NTT Collection" exhibit has been held annually since 1987. This is our biggest exhibition, and it rolls out our latest technologies, products, and services.
The exhibit is open to our customers, and the public, and virtually every major company in Japan came by to see what we have to offer and what is in store.

5.3 DATES

October 15, 1990	• Presentation to the press
October 16, 1990	• Presentation to specific large customers
October 17, 1990	• Presentation to specific large customers
October 18, 1990	• Presentation to specific large customers
October 19, 1990	• Presentation to the general public
October 20, 1990	• Presentation to the general public

5.4 PLACES

NTT Collection was held at the NTT TWINS Building in Shinagawa, Tokyo.
The counterpart places overseas in the Global ISDN presentation was demonstration centers of counterpart common carriers and terminal manufacturers.

5.5 THE COOPERATORS OF THE DEMONSTRATION

Five overseas common carriers, KDD, and a number of as terminal manufacturers cooperated to ensure the success of the demonstration.

5.7 DEMONSTRATED APPLICATIONS (SYSTEM CONFIGURATIONS)

See Attachment

5.8 ISDN CONSULTING CORNER

A global ISDN consulting corner was set up next to the demonstration corner. One representative from each of the carriers' was assigned to the corner to explain the carriers' ISDN service offerings and answer a lot of questions.

6 IMPACT OF THE DEMONSTRATION

"NTT Collection '90" attracted about 40,000 visitors and 150 members of the press through the session. A lot of visitors touched the global ISDN applications directly and realized the usefulness of global ISDN. In general, they showed a keen interest in global ISDN applications. Especially, the demonstration of the floppy disk data transfer system, with capability to transmit 1 Mbyte of data between Japan and the U.S. quickly and easily, was a crowd pleaser. Also, BT sponsored press event effectively by using the video conference between Japan and the U.K. with "CCITT standardized CODEC", and attracted the members of the press participated in the U.K.

About 100 visitors took advantage of the consulting corner for global ISDN. Most of them asked questions, supposed an actual use of global ISDN. Among them were what terminals were available among what countries or carriers, how long it would take before ISDN is available in each country, and to what extent communication costs could be cut.

7 THE ISSUES IN POPULALIZATION OF GLOBAL ISDN

Through holding the demonstration of global ISDN at "NTT collection '90", NTT realized how it was time-consuming to make global ISDN available. In order to make the global ISDN links available, NTT had to hold several connection testing between Japan and the overseas countries. Also, to select available applications NTT had to search on what terminal equipment by what vendors was available among what countries or carriers, by holding connection testings carefully. These things were very difficult, thinking of the time differences between Japan and these countries. The demonstration could not have succeeded without the close collabolation of common carriers, terminal manufactures, and customers.

As mentioned in section 4, significant barriers to global ISDN remain including the limited range of terminals, and problems stemming from technical differences among countries (e.g. the transmission speed difference between the U.S. and other countries). NTT has researched the availability of terminals that can be used for global ISDN links and summarized the findings in a brouchure, called "Global Application" for customers who would take advantage of ISDN but don't know how. Through this effort, NTT realized the range of available terminals are almost limited to between the same models, or more, between the same vendor's models, and that in fact, few end-to-end connection testing of terminals on global ISDN link has held so far.

To overcome these barriers, telecommunication carriers, terminal equipment vendors, and customers around the world must collaborate much more closely. More specifically, this will involve end-to-end connection testing and clarification of global ISDN terminal availability.
NTT expects that the activity to promote the National ISDN 1 (NISDN 1) in the U.S. would be helpful to overcome the barriers, and that the demonstration, called "TRIP '92", one of the most important activity to promote NISDN 1, which will be held by the North American ISDN User's Forum (NIUF) in November 1992, would succeed in promoting NISDN 1 in the U.S. and promoting global ISDN.
Through the collabolation, NTT hopes that the day will come soon when peoples all over the world are connected by ISDN.

Storage concepts for moving picture database on B-ISDN

J. Kishigami, N. Sakurai, and H. Nakano*
NTT Network Information Systems Laboratories
** NTT Human Interface Laboratories*
Yokosuka, Kanagawa, Japan

1. Abstract
We present some concepts necessary for the network file system in B-ISDN, in particular for the handling of moving pictures. From the view points of architecture and hardware, multiple-access can be considered the most important factor in the network file. A prototype network file system as an infrastructure for the advanced storage system in B-ISDN is also presented.

2. Introduction

Recently, a great amount of research has been done on the Broadband Integrated Services Digital Network(B-ISDN) especially the area of network architecture. Outside of this study, however, there has been almost no detailed discussion on the B-ISDN storage system. If data were to be treated on B-ISDN in the same way as it is in existing networks, the storage system, which is called the network file in B-ISDN, would not require any drastic changes. However, the most highly anticipated new developments in B-ISDN is said to be the various services that will based on visual database systems. The basic concept of the network file system that will be used in the near future is shown in Fig. 1. With such a system, users can access any database they desire through B-ISDN[1,2].

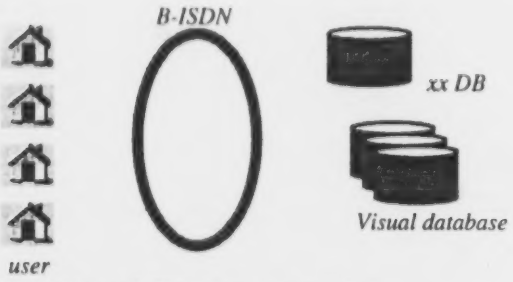

Fig. 1 Network file system concept view

From a technical viewpoint, one of the most significant factors is the sheer amount of visual data, which exceeds the amount of conventional code data by more than one hundred times. This vast amount of data coupled with the fact that it should be reproduced at a constant rate necessitate a very fast transfer rate along the order of several MB/s. This rate refers to not only the transfer rate between disk and controller, but also BUS speed and network transmission speed. To satisfy the rate requirements, SCSI-2, IPI-3 BUS and B-ISDN, and FDDI network have been proposed. Basically, there are two approaches to these technologies. One is to increase the BUS transmission speed itself. The other is to use a parallel transmission method.

The characteristics of visual data also make it necessary to devise a way of managing it, that is very different from the way which conventional code data is managed. Most kinds of visual data will be used in the database system, therefore interactivity is the most important factor to include in the database. However, it is very difficult to achieve interactivity when working with visual data because this kind of data is basically time-oriented.

Furthermore, visual data should be synchronized with other forms of attributed data, such as audio or text data. Recently, some experimental systems which can synchronize moving picture data with audio data that are based on concept of a logical time system have been reported[3]. In these systems, only the software is used to control the synchronization. It is true that this software control is very important, but synchronization can be made easier by using time recognition in the storage system. File allocation of moving pictures presents the same problem. The difficulty for a visual database in terms of file allocation is caused by its vast quantity and its time-dependency. We will discuss these problems in this paper.

3. Multiple-access method

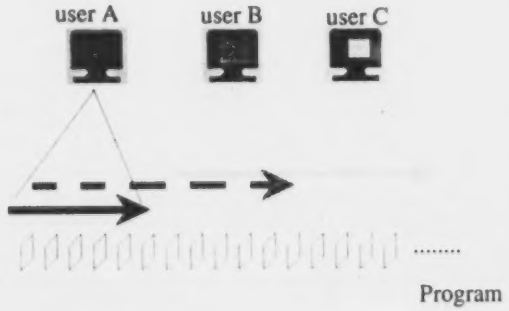

Fig. 2 Multiple-access image

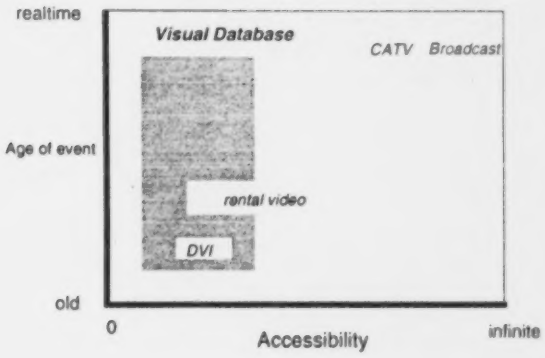

Fig. 3 Accessibility vs. freshness

The most important requirement for the visual database storage system is to provide multiple access to the same moving picture. Figure 2 shows the case when many users are accessing the same program which images time bar of moving picture data. Users access the program randomly in terms of time and place. To provide this kind of service, the system needs very advanced multiple-access technology because of the characteristics of moving picture data.

There are several ways of realizing this multiple-access function now, the most practical of which is the "copy" technique, which is also the cheapest way at present. This method is used in CDs, music tapes, magazines, and newspapers.

People can gain access to the same program content in this way. Even in the field of visual databasing, the copy technique is widely used, in as rental video shops for instance. Figure 3 maps several kinds of media from the point of view of accessibility and age of events. The most important aspect of the database is interactivity. Interactivity is defines as very fast accessing in this paper. Bellcore introduced an on-demand television service based on the copy technique two years ago in what can be considered as the first presentation of multiple-access for visual data[4]. However, with this service, the user often has to wait around several hours because of the slow coping process. We present here a more practical and adequate system for a visual database that does not use the copy technique. Our approach allows several users to access the same moving picture data within a few seconds of each other, making it a truly interactive access system.

There are many possible candidates that can be used to construct this system. From the viewpoint of performance, the use of a silicon file is the most adequate because of its very fast accessing time. However, its very high cost precludes its use. Moreover, the amount of data in a one-hour NTSC television, for instance, is more than two giga-bytes, requiring total filing capacity of roughly several tera-bytes for one system. From this viewpoint also, silicon files are not practical. Other file systems, such as magnetic tapes, optical disks, etc., are not yet fully adequate because of their very poor accessibility. If these systems can attain very fast access rates in the near future, using them may become feasible. Currently, disk arrays provide the very fast transfer rate for necessary achieving interactivity.

4. Basic Concept for the network file

Conventional storage is designed based on "byte count". This is because byte loss can not be allowed in the processing of code data. Only by supervising "byte count" can software be kept independent from storage performance parameters, such as transfer velocity and access time. In terms of the storage function, faster data transfer is only required for a controlled FIFO queuing mechanism, as shown in Fig. 4. This architecture also helps to achieve high storage performance as well.

However, in handling audio or visual data, a conventional byte-oriented storage system loses some of its flexibility in upgrading performance. This is because audio or video data should be reproduced at its own constant velocity. If, for example, a compact disk player controlled the CD rotation at various speeds, the reproduced sound could not be recognized as music. The easier way to use a conventional storage system for these kinds of data is to maintain a constant length and speed. In this case, however, the data

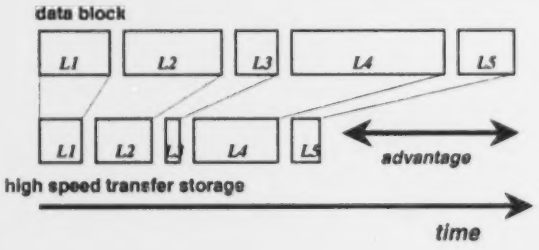

Fig. 4 The conventional storage architecture based on "byte count"

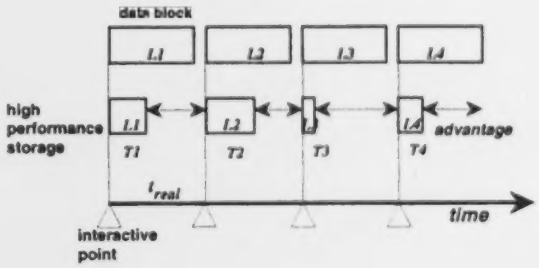

Fig. 5 The data transfer concept for the network file storage based on "time compression"

format has to be reconsidered every time the storage is upgraded. Moreover, the effective data transfer rate at the user terminal will not be constant.

In data transfer, it is not necessary for the time of data transfer T to equal the time to reproduce t_{real}, but it is necessary for data transfer to be complete before the beginning of the next data block, as shown in Fig. 5. The required buffer size depends on the the terminal processing power. This means that if the storage system recognizes the time t_{real}, it will perform more flexibly. Here a time compression rate TC defined as

$$TC = T / t_{real},$$

is introduced as a way to improve the storage performance. *Here*, t_{real} would be the minimum interactive period in the visual database, and T depends the storage performance. Smaller TC can improve storage subsystem capabilities. The new storage concept described in the following section serves as the basis for control TC.

4.1 Multiple-access capability

The most important requirement for a visual database network file is to allow many users to access at anytime, the same moving picture data. This requirement can be satisfied by using a time-based storage system which can maintain TC as

$$TC < 1 / MAC,$$

where MAC stands for Multiple-access capability and means the number of users who can access the same moving picture data at the same time. Figure 6 shows the case when many users are accessing the same program, which is shown as a time bar of moving picture data.

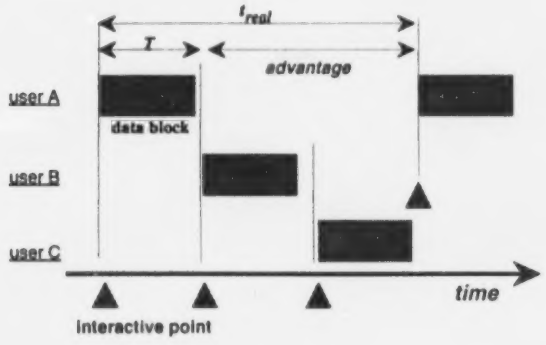

Fig. 6 Multiple-access to the same moving picture data

4.2 File acquisition loss

When the user the skips from one scene to another during an interactive order, the required moving picture data may not be located at the continuous storage area. In the worst case, it would be stored in another storage system in the network. Maintaining a continuous reproduction of the moving picture data stream requires

$$TC < 1 - T_{connect} / t_{real},$$

where $T_{connect}$ is the overhead time needed for a user terminal to search and connect to another storage area. The storage system itself cannot control this time, so the controller needs to send the information from the terminal to the storage system. Figure 7 shows the time bar the different storage systems are linked. If multiple-access is allowed in a linked storage system, TC is described as

$$TC < 1 / MAC - T_{connect} / t_{real}.$$

4.3 Hardware approach to multiple-access

TC can be concretely described by using the hardware parameters

$$TC = \frac{t_{real}}{T} = \frac{t_{real}}{T_{acc} + \frac{L(t_{real})}{V}},$$

where T_{acc} is the maximum access time including one rotational time and the maximum seek time, V is the transfer rate from or to the storage system and $L(t_{real})$ is the transfer data length in one interactive period which is related to t_{real}. Among these parameters,only V, T_{acc} and $L(t_{real})$ can be controlled.

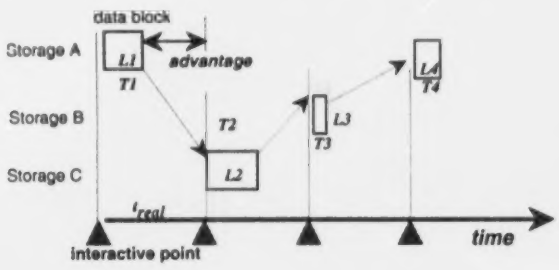

Fig. 7 The linkage to the distributed moving picture data

V is clearly the most sensitive parameter, because $L(t_{real})$ is very huge when moving pictures are handled. This means that the network file must enable high-speed transfer with a low overhead physical interface. Parallel transfer technologies, such as disk arrays, are very suitable for this purpose. $L(t_{real})$ is generally not a variable parameter, at least in code data processing. The compression technologies for the moving picture which are represented by MPEG, JPEG etc.[5,6] point to the possibility of controlling $L(t_{real})$ by the storage system. If storage could control the compression rate or method according to the TC requirement, the effect would be equal to one when V is increased. When $L(int) / V$ becomes small through the high-speed transfer technologies or a high-capability compression method, T_{acc} becomes significant. However, it is difficult to decrease an access time, which depends on the mechanical factors, in the near future.

As mentioned above, the creation of a moving picture database depends upon improving storage performance to the point where interactive points can be recognized. In other words, the highest priority of the storage for a moving picture database is to complete the transfer of the requested data in time for the next interactive point, even if a acceptable level of byte loss occurs. The first step toward improving in the storage architecture for moving pictures is the introduction of switching control mechanism that can monitor the timing of the interactive point for each user. This approach, which is used in our proposed, will be described later in this paper. The next step requires the recognition of the time-based characteristics of the stored data as the parameter to control the effective transfer rate.

4.4 Hierarchical architecture

Conventional storage hierarchy provides random access storage. At the higher level of this form of storage, such as the "on-line" file storage in RAM disks and HDDs, offers high performance at high cost. At the lower end, there is sequential access storage such as the "the off-line storage" in MTs, that offers large capacity at lower cost. Recently a library system with an automatic media handling mechanism has replaced the stand-alone MT. That acts as a "near-line storage" method. This hierarchical storage system is usually controlled so that the active data is registered in the higher level and inactive data is copied from the lower level to the higher level by the staging architecture when the data is accessed.

This architecture is most effective in handling short file[7,8]. If the staging architecture is adopted to moving pictures, it would take a very long time to copy it from an off-line file to an on-line one. Because the fast response time is so vital to achieving the interactivity that will satisfy user demands. Architectures based on staging are not suitable for moving pictures. Such an architecture is also unsuitable from the viewpoint of storage system cost. Figure 8 shows a staging model from which the data block is accessed after being loaded from the MT to HDD and a non-staging model from which the data can be accessed directly such as an ODD with sufficiently high performance to be connected to B-ISDN.

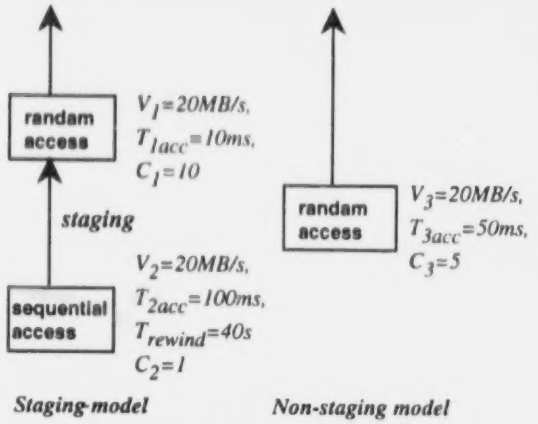

Fig. 8 The model of the staging or non-staging architecture

The cost for the staging model can be evaluated as

$$cost = (C_1 + C_2) \times T_{(staging)} + C_2 \times T_{(rewind)} + C_1 \times T_2 \text{ (online)},$$

while the cost for the non-staging model is

$$cost = C_3 \times T_3 \text{ (online)},$$

where,

$$T_i \text{ (online)} = N \times (T_i \text{ (acc)} + L / V_i) \quad (i = 2,3), \quad N: \text{Number of access}.$$

Details of the evaluation method can be found in [7,8].

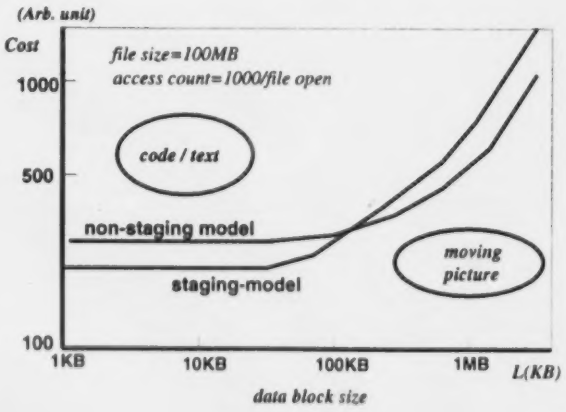

Fig. 9 The hardware cost saving effect by the staging architecture

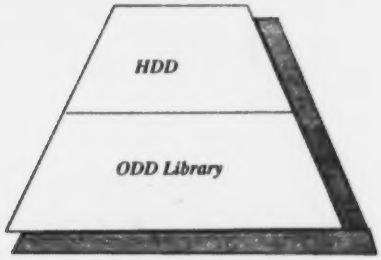

Fig. 10 The storage hierarchy for the moving picture data

Here, C_i means hardware cost per unit of capacity while maintaining the required performance. Figure 9 shows the relationship between the block size and the savings in storage cost achieved by staging. This figure shows that staging cannot save hardware cost when moving pictures with a large block size L are handled, indicating sequential access storage will not be effective for moving pictures. On the other hand, a library which can automatically handle the inter-changeable random access volume, such as an optical disk cartridge, is required at the lowest level of the storage hierarchy because the amount of inactive data will increase more and more so that important moving picture data can be stored for a long time. The storage hierarchy for the moving picture data is as shown in Fig. 10.

5. *MAMI* technique

We propose here a Multiple-Access for Moving picture Information (*MAMI*) system. That can perform the multiple-access function for moving pictures through a network or BUS[9].

5.1 Schematic view

As previously described, constant reproduction and multiple-access methods for visual database are *MAMI*'s most significant functions. The former function was gained by improving the effective transfer rate to *1/MAC* times. This control is achieved by supervising the real time needed to transfer through the use of a real time operation system. NTSC television needs 30 frames / 60 fields per one second. Of course, these frames should be reproduced at a constant interval. In other words, a user can not accept data as code data sent as a packet. The client module controls the speed of input and output. The problem in the *MAMI* system is how to achieve a high-speed transfer rate.

The most important point to consider is disk array technology. Figure 11 shows the mapping where a typical hard disk and optical disk are plotted. Achieving multiple-accessibility requires an array technique such as that described in this figure.

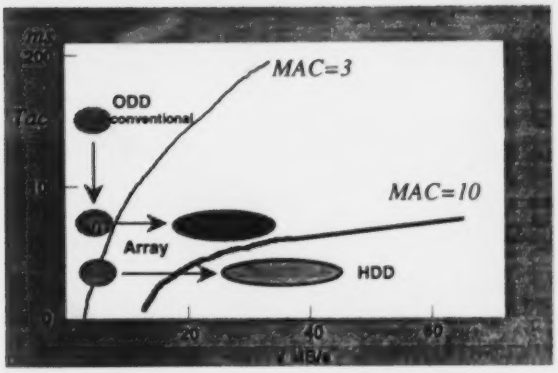

Fig. 11 Access time vs. transfer rate

$$MAC = \frac{T_i}{T_{acc} + KL/V}$$

T_i: *Flexibility* (interaction capability)
L: *Visibility*
T_{acc}, K, V: Hardware performances

Here, it would appear that L represents visibility, and T_i represents interactivity. At first, T_i was assumed as one second. Under this restriction, T_{acc} and V cannot be realized with a conventional disk, as shown in Fig. 11. This equation also shows that if a user can wait a long time, T_{acc} would not be an important factor. Only the copy approach would be effective in this case.

5.2 Hardware improvement

In this section, some important technologies for a storage system which files moving picture data are described. The first one is a fast transfer technique. In the recent past, some disk array systems in a commercial base have been announced. Most of them can be recognized as off shoots of RAID-3, which was proposed three years ago[10]. Two of the five categories proposed by Katz et al., are the concepts of reliability and fast transfer rate. The concept of reliability does not seen to be important for visual data; reportedly an error rate of less than 10^{-5} would be sufficient. This is equivalent to a rate of one error per pixel, a rate which most people would not consider important.

832

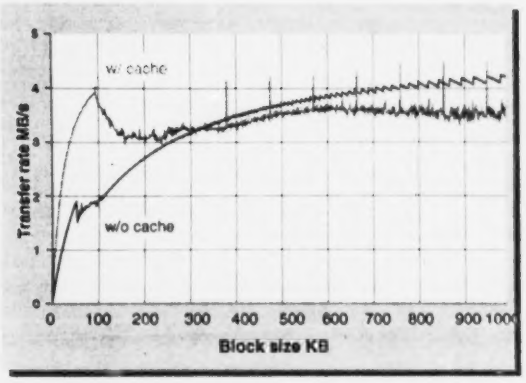

Fig. 12 Transfer rate vs. block size

A disk array system provides a very fast transfer rate as a function of various kinds of conditions. Block size is one of the most effective parameters affecting transfer rate. This effect is shown in Fig. 12. A UNIX file system generally supports 8 KB block transfer. As this figure shows, such a small block size can not support a fast transfer rate. In this case, the cache method would be very effective. This figure also shows that a very large block size should be applied for visual data. The *MAMI* system, which uses VxWorks OS as real-time operation, adopts a block size of around one MB. This OS does not have its own internal file system. Therefore, a very effective file system can be flexibly constructed.

One more important function is BUS performance, which includes internal and external interfaces. One conventional system has been tuned for short code data which does not need a fast transfer rate. Recently, some fast interfaces for disk systems have been announced. The SCSI-2 was adopted in the *MAMI* system from the point of cost. Some special interfaces exist that can achieve very high performance, but they are not economical. Visual data needs to be stored in a cheaper way because of its vast quantity.

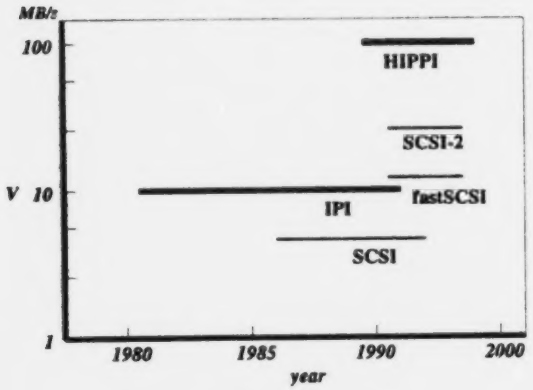

Fig. 13 BUS performance

6. Conclusions

The network file system is vital part of the infrastructure in a B-ISDN system especially for the handling of moving pictures. True multiple-access to moving pictures, represents the most significant aspect of network file systems from the viewpoint of architecture and hardware. We proposed a viable alternative to current multiple-access methods for moving picture data in B-ISDN that we call *MAMI*. The *MAMI* system is based on the disk array subsystem technology, scheduling techniques, and constant transmission techniques. Various kinds of B-ISDN services, especially those utilizing moving picture data, will use this technology in the near future

To Market, To Market: ISDN in Hawaii

Suzanne M. Neufang
University of Hawaii-Manoa
Honolulu, Hawaii USA

1. ABSTRACT

ISDN is scheduled for introduction to Hawaii in early 1992. Without the benefit of having had ISDN field trials in Hawaii, local businesses and the market they represent may leave the fate of ISDN's success in the hands of its providers.

2. INTRODUCTION

"ISDN hits Hawaii Market."

So will read the headline in early 1992 if all goes according to the plans of GTE Hawaiian Telephone Company, Hawaii's local exchange company (LEC). The road to getting ISDN in Hawaii has been a cautiously bumpy one -- and it's far from being without more proverbial potholes along the way to full implementation.

3. ISDN PROGRESS: PERCEPTIONS AND MARKETS

One can follow the stop-and-go progress of Integrated Services Digital Network with a quick look at how it has been portrayed in American telecommunication trade journals.

For years, the perception among these trade journal authors has been one of general optimism toward ISDN. Initially there were the explanatory articles describing what it is. Then came the articles on the standards-making process, the ISDN field trials, and finally the success stories of those corporations which are making unlimited progress in their business aspirations via this digital network that the telecommunications industry had been constructing for nearly two decades.

But nothing seemed to be happening very fast. After all, after ten years of articles about the same digital "superhighway" -- and it still hadn't materialized commercially -- there had to be some major roadstops somewhere. At times readers could catch a glimpse of what was holding ISDN back: a prolonged standards-making process, delays in the digitization of central offices, the lack of customer premises equipment, regulatory hurdles, market interest.

Market interest?

How could a global network conceived to take care of every possible business -- and residential -- communication problem and need have trouble getting its foot in the market's door? The problem is apparent: Not many corporations in the United States today have embraced ISDN, even where it is available (unlike personal computers, facsimile or LANs), nor has corporate America been pounding on the door of the LECs to "let them in" to the ISDN network. There are, in fact, indications that corporate telecommunication managers know as little about ISDN as they did when the concept of ISDN first appeared. In any event, they are skeptical of its promise (1).

Hawaii certainly is no exception to this general trend of skepticism, making the step toward ISDN a slow and cautious one. (ISDN is expected to make its appearance in Hawaii during the first quarter of 1992.)

This caution is in sharp contrast to Hawaii's Pacific neighbors -- Singapore, Japan, Hong Kong, Taiwan and others -- who are actively pursuing state-of-the-art ISDN systems (with corporate and residential users in mind) to the extent of implementing broadband ISDN (B-ISDN) in the near future. Many U.S. mainland counterparts, as well, have seen recent progress -- albeit less encompassing -- in commercial ISDN applications. Which markets are they tapping? Finance, medical, retail, high technology... industries transporting high volumes of data that need ever-increasing speed, the lowest possible error rates and economical rate structures. Hawaii has her own share of organizations falling within these categories.

4. HAWAII'S MARKET FOR ISDN

With a cautious attitude on the part of Hawaii's LEC, it is no wonder that Hawaii's local market is, at best, guarded toward the idea of adopting ISDN.

Similar to recent mainland U.S. studies, preliminary results of a survey of Hawaii's largest businesses -- within industries targeted by GTE Hawaiian Tel as most likely to adopt and implement ISDN (2) -- show that a large proportion of telecommunication/voice/data managers in Hawaii know little about ISDN. In fact, as their knowledge of ISDN grows, so does their skepticism of ISDN as a user-friendly/economically viable network alternative. Most feel the risk is high to adopt ISDN within 1-2 years. Very few had been approached by GTE Hawaiian Tel regarding ISDN service.

While still preliminary, the implications of the survey results are startling. GTE Hawaiian Tel officials state that market readiness is one of two main reasons why ISDN has not yet been implemented in Hawaii. (The other reason is lack of universally accepted standards which, with the implementation of National ISDN-ONE in mid-1992, is already on the road to resolution.) What is being done to make the market in Hawaii more ready -- or at least more informed

BEST COPY AVAILABLE

-- so that telecom managers can make informed choices about adopting ISDN or not once it's here?

One ISDN information dissemination outlet has been the Hawaii Telecommunications Association (HTCA), a local organization with about 200 members. While a fairly comprehensive report is given each year on the state of telecommunications and coming changes (including ISDN) in Hawaii, less than 50 percent of the people surveyed (in charge of planning telecommunication systems among Hawaii's largest businesses) belong to the organization. Apparently, without direct contact from a telco representative, they have only trade journals and industry hear-say to keep them up to date on any ISDN developments.

Until ISDN promotion reaches their own conference rooms, it seems unlikely that they will be among the first to adopt ISDN once it is offered.

5. THE STATE'S QUEST

For several years, Hawaii has tried to promote an image of linking East with West -- via transportation and telecommunication systems. While Hawaii was an early participant in submarine cable communication (1957), the state has since lost ground in its quest as a technological innovator. Much like the nonstop flight between Japan California, telecommunications undersea cables and satellites are doing their fair share of bypassing Hawaii.

ISDN has the potential of opening up the state's doors to the kinds of business that would diversify its economy from its current tourist-dependent base to one with a technology base (3). (The reasons to pursue such diversification are many, including protection against economic downswings, as Hawaii experiences just a year ago during the Gulf crisis when tourist numbers dwindled. The high-paying, environmentally safe information technology-related industry would also lend itself nicely to Hawaii's high cost of living and its image of environmental purity.)

Since 1988, the state legislature has attempted to encourage such diversification through telecommunications and information technology, with the establishment of various agencies to promote and develop applications and business niches in Hawaii that entrepreneurs and businesses based elsewhere would find lucrative. These agencies include HAWAII INC and the High Tech Development Corporation. As yet, not much has gone beyond these activities to develop Hawaii's vast potential in that arena.

On the other hand, without the state-of-the-art infrastructure in place (without basic ISDN, after all, there can be no B-ISDN), harm may actually have been done in luring potential businesses to Hawaii. Case in point is the recent failure of the proposed stock exchange in Hawaii, which couldn't get off the ground because of the lack of Japanese brokers' interest (4). (You can't have running water if you don't have the pipes to carry the water.)

6. DIGITAL ISLANDS

Within the context of ISDN, it is irresistible to link the now popular metaphor of "digital/ISDN islands" with the Hawaiian islands. The geographic reality of Hawaii as a group of islands with the potential of also becoming a "digital/ISDN island" makes it an intriguing task to put these two concepts together.

There is, however, an interesting paradox to this linkage: While ISDN "islands" on the U.S. mainland or elsewhere suggest some sense of isolation, of incompleteness in their communication/technological systems (until they're linked to several other islands, or until the whole system is ISDN), Hawaii would seem to have an advantage as an ISDN island, with unlimited interconnection capabilities with the outside world -- to the north, south, east and west. (After all, with or without ISDN, Hawaii remains, in all cases, an "island.") A telecommunication system that is the most technologically advanced possible -- if economically feasible -- would surely increase Hawaii's "communication and cultural crossroad" value. It would also enhance intra-state development and communication, from island to island, outside of the metropolitan Honolulu area. Bypass would no longer be an issue.

Not all telecommunication watchers and users, however, are excited about the introduction of ISDN, saying the technology it provides is already "old," or that the investment necessary to complete an ISDN will come at the expense of other telecommunication development. Could it be that Hawaii is more "on track" by being "off track?" Some telecom managers are looking more forward to the state's proposed Switched Digital Network which will offer ISDN-like data transport in early 1992 than they are to actual ISDN.

7. ISDN PROSPECTS

Predictability is a dubious quality. For all the years spent planning, standardizing and implementing ISDN, there is still no industry-wide formula for its success.

ISDN is coming to Hawaii. But whether it is a success among local businesses depends on its rate structure, applications and marketing. For what is most certainly predictable is that without proper and thorough educating and marketing on the part of the telecom providers, ISDN will have to wait still longer to realize its full potential in the Hawaii market.

AUSTRALIA'S NEW TELECOMMUNICATIONS REGIME
THE OPPORTUNITIES EXAMINED

Raymond P Kiley
Senior Associate, Baker & McKenzie
Sydney, Australia

1. ABSTRACT

During the course of 1991, the Australian Government has introduced substantial reforms to Australia's telecommunications industry. These reforms include the establishment of a private sector competitor to the Government owned Telecom and OTC, the merger of Telecom and OTC, the liberalisation of enhanced services and the introduction of the resale of network capacity. These changes have been occurring rapidly as the new telecommunications regime continues to evolve. This paper will provide a brief history of Australia's telecommunications regulation, an overview of the regulatory structure of the current telecommunications regime and a summary of the most recent developments in Australia's telecommunications industry.

2. RECENT HISTORY OF TELECOMMUNICATIONS REGULATION

2.1 PRIOR TO 1988

Prior to the commencement of the Telecommunications Act 1989 the Government owned Australian Telecommunications Corporation (known as "Telecom") had exercised considerable control over both the provision of domestic telecommunications services in Australia and the regulation of the telecommunications market. The Telecommunications Act 1975 specifically prohibited persons other than Telecom from erecting, maintaining or operating telecommunications installations or attaching lines, equipment or apparatus to a telecommunications system. As these terms were given broad definitions in the legislation, private enterprise was, for the most part, excluded from participation in the telecommunications industry.

2.2 THE MAY 1988 REFORMS

In May 1988 the Minister for Transport and Communications announced significant reforms which resulted in a package of legislation being passed with effect from July 1, 1989. The reforms set out in the Minister's statement and subsequently introduced included:

(a) an authority for the carriers (Telecom, OTC and Aussat) to be the sole providers of basic network facilities and services, subject to the imposition of greater commercial and external regulatory discipline;

(b) full scope for competition in the provision and operation of value added (enhanced) services;

(c) increased scope for competition in the provision and maintenance of network terminal equipment for connection within customers' premises, in particular PABX and small business systems; and

(d) the establishment of regulatory arrangements directed towards insuring maintenance of minimum necessary standards, fair and efficient competition beyond the monopoly boundaries and approved efficiency and accountability for the monopoly carriers.

A complimentary statement issued by the Minister gave rise to reform of the day to day management of Telecom, OTC and Aussat reducing the Government's control over their day to day management.

2.3 THE NOVEMBER 1990 STATEMENT - FUNDAMENTAL REFORMS

Telecommunications policy objectives came under renewed focus with a release of the Government's statement in November 1990 on micro-economic reform in the telecommunications industry. The package of reforms foreshadowed by the November statement included:

(a) the merger of Telecom and OTC to form a corporation to be governed by the Corporations Law and to be known as the "Australian and Overseas Telecommunications Corporation Limited" ("AOTC");

(b) the commitment to the establishment of a private sector competitor to AOTC in the provision of network facilities;

(c) each of AOTC and the second general carrier to be licensed to provide the full range of telecommunications services and facilities domestically and internationally;

(d) greater competition in the provision of telecommunication services (subject to limited exceptions) including unrestricted third party resale of capacity acquired from the carriers;

(e) a substantial increase in the powers of AUSTEL, the independent regulator; and

(f) the termination of Telecom's right to exclusively supply the "first" telephone from June 30, 1991.

The November 1990 statement involved a total of 83 Government initiatives.

2.4 JULY 1, 1991 - THE NEW LEGISLATIVE FRAMEWORK

In June 1991 a package of legislation received Royal Assent and subject to certain transitional provisions effected the repeal of the then existing telecommunications legislation. The new telecommunications legislative package implements the proposals set out in the November statement, subject to certain modifications adopted by the Government following representations made by the public. The legislation lays the ground work for the introduction of a private sector competitor to compete with the merged Telecom/OTC (AOTC) through a statutory scheme for the licensing of "general carriers" who are to be the primary suppliers of Australia's telecommunications networks and services.

The Government has stated that the duopoly created by the introduction of a competitor to AOTC will terminate on June 30, 1997. Although the legislation does not contain an express term specifying the duopoly period the duopoly has been established, and will be terminated, through the Minister's exercise of his powers to issue licences to "general carriers".

2.5 RECENT DEVELOPMENTS

Since July 1, 1991 the new telecommunications regime has continued to evolve. Some of the major developments include:

(a) the announcement that Optus Communications Pty Limited ("Optus") has been selected to be Australia's second telecommunications carrier;

(b) the annoucement that the moratorium on pay television will be lifted;

(c) the grant of a general licence in respect of cordless telephones;

(d) the grant of a general licence in respect of the resale of domestic telecommunications capacity;

(e) the decision of the Government to proceed with the issue of the third mobile telephone service; and

(f) the announcement by the New South Wales Government that it will establish its own private network.

Details of these recent developments are discussed below.

3. STRUCTURE OF THE TELECOMMUNICATIONS REGIME IN AUSTRALIA

3.1 LEGISLATIVE STRUCTURE

The legislative structure of the telecommunications regime in Australia is comprised of the following principal Acts:

(a) the Telecommunications Act 1991 (the "Telecom Act") - replaces the Telecommunications Act 1989 and forms the basis of the regulatory regime including the licensing of general carriers and the relationships between the general carriers, consumers and services providers; and

(b) the Australian and Overseas Telecommunications Corporation Act 1991 - establishes the Australian and Overseas Telecommunications Corporation (AOTC) which will be the successor to all the rights, property, staff and liabilities of Telecom and OTC on a day to be fixed by proclamation and determines the power of the Minister to specify price control or price notification and disallowance requirements and to determine principles to govern price control arrangements.

333

Other supplementary Acts regulate such matters as transitional provisions, consequential amendments and fees. Other Commonwealth legislation, including the Trade Practices Act 1974 and the Broadcasting Act 1936, will continue to have an impact on the Telecommunications industry.

3.2 ADMINISTRATION

Responsibility for telecommunications regulation in Australia falls primarily on the Government, through the Minister for Transport and Communications. The Department of Transport and Communications exercises the Minister's day to day responsibilities.

The Telecom Act continues the existence of AUSTEL as an independent regulatory body and increases its powers. The functions of AUSTEL now include:

(a) the economic and technical regulation of the Australian telecommunications industry including the promotion of fair and efficient market conduct, giving advice and assistance to the industry, and giving reports and advice to the Minister;

(b) the promotion of competition within the telecommunications industry including facilitating the entry of persons into markets for services and facilities and promoting competition among the general carriers;

(c) ensuring that the provisions of the Telecom Act are carried out with due regard to the public interest;

(d) receiving and investigating complaints; and

(e) the issue of class licences and permits under the Telecom Act.

In addition, Australian telecommunications regulation is influenced by international conventions. For example, under section 48(c) of the Telecom Act, AUSTEL must perform its functions in a manner consistent with Australia's obligations under any convention of which the Minister has notified AUSTEL in writing.

3.3 THE CARRIER MARKET

Part 5 of the Telecom Act provides for a licensing scheme to apply to telecommunication carriers. Section 55 of the Telecom Act states that the object of Part 5 is to help the objects of the Act by:

(a) establishing a system for licensing "general carriers" on the basis that they are to be the primary providers of Australia's line based and satellite based public telecommunications capacity and the primary suppliers of telecommunication services by the use of "line links" and satellite based facilities; and

(b) establishing a system for licensing mobile carriers on the basis that they are to be the primary suppliers of public mobile telecommunications services.

To give effect to the above, two classes of licences will be issued. The first, "general telecommunications licences", are to be issued to "general carriers". General carriers are to have facilities based reservations. The second category, public mobile licences, are to be issued to "mobile carriers" who are to have certain preferential rights with respect to mobile communications.

Initially, there are to be only two general carriers. These two carriers are to operate under a duopoly structure until June, 1997, after which additional licences may be issued. One of the two general carriers will be AOTC, the merged Telecom/OTC. On November 19, 1991 the Government announced that the other general carrier will be Optus. Optus is an Australian company which is 51% Australian owned. The Australian shareholders are Hayne Nickless, AMP and National Mutual. The overseas shareholders, who together own 49%, are BellSouth and Cable and Wireless.

The public mobile licences are to be issued to each of the two general carriers and a third licence is expected to be issued during 1992 to come into operation in 1993. A submission made to the Government that the third mobile licence be constituted by several regional licences has been rejected.

The general carriers are to have reserved to them the right to install and to maintain "line links" between "distinct places" within Australia. This reservation takes the form of a prohibition on a person other than a general carrier (or a person acting on behalf of or together with a general carrier) installing or maintaining "reserved line links" and a provision which entitles a general carrier to install or maintain such line links. "Line links" include physical lines, cable, and optical fibre. "Reserved line links" comprise line links between

distinct places within Australia or between a place within Australia and a place outside Australia.

The legislation does not confer on the general carriers the exclusive right to operate facilities as the resale of network capacity is now permitted and such resellers will be entitled to operate networks. Also, as the carrier reservations are framed in terms of "line links" there is no restriction on the installation, maintenance or operation of switching facilities.

Certain exceptions will apply to the general carriers' reservations including the following:

(a) line links used by certain transport authorities for their business requirements;

(b) line links used by broadcasters for certain purposes;

(c) line links authorised under previous legislation;

(d) certain line links installed by defence organisations necessary or desirable for defence purposes;

(e) private networks; and

(f) authorisations of third parties by AUSTEL to install, maintain, use or dispose of line links or satellite based facilities.

Although the general scheme of the new legislation is that it does not reserve to the general carriers the right to supply services the general carriers will have reserved to them the right to act as the initial suppliers of services by satellite. Whilst third parties (for example Intelsat) may supply satellite services to general carriers, resellers or others utilising such satellite services must acquire those services directly or indirectly from a general carrier. It should be noted that part of the grant of the second licence to Optus includes the sale of Aussat to Optus.

The Telecom Act provides that only the holders of "public mobile licences" will be entitled to act as the initial suppliers of "public mobile telecommunication services". Whilst third parties may act as resellers of such services, a mobile carrier must be the initial supplier of the service, directly or indirectly. Public mobile telecommunication services are distinguished from other non-reserved services mainly by the existence of cell handover capabilities.

Certain services are excluded from the definition of "public mobile telecommunication services", such as trunk mobile services, one-way only store and forward communication services or similar services such as paging services. The legislation distinguishes between "public mobile telecommunication services" and "public access cordless telecommunication services", which are not reserved services.

3.4 PROVISION OF VALUE ADDED OR ENHANCED SERVICES

Under the Telecom Act "eligible services" is the term used to regulate and to define the rights of service providers under the new liberalised regime. Eligible services are defined under Section 18 of the Telecom Act to mean either:

(a) a telecommunications service supplied by means of at least one reserved line link or facilities including at least one reserved line link; or

(b) a telecommunications service supplied by means of satellite facilities.

Eligible services include a broad range of activities including the resale of capacity, both domestic and international, traditional "enhanced" services such as network managing, bureau activities, video conferencing and store and forward services; operators of private networks utilising capacity acquired from the carriers for their own use who may wish to resell spare capacity; and public access cordless telecommunications services.

Eligible service providers have the right to have their services connected to the networks of the carriers provided that the service is supplied under a class licence issued by Austel.

3.5 PRIVATE NETWORKS

Pursuant to the Telecom Act the general carriers have the exclusive right to install line links between "distinct places". However, within a distinct place a private party may install, maintain and operate its own network. A "distinct place" is a property over which there is a single legal title, but excluding parts of that property which are leased, sub-leased or used by other parties. Adjoining properties under the ownership or lease of the same party or parties having a "shared interest" can be aggregated into a common area and a privately owned and operated network connecting the individual properties in that common area can be installed. This

will allow, for example, a company which leases several adjoining sites to establish a single network over all the sites.

The definition of "distinct place" has been drafted carefully to avoid arrangements entered into for the sole purpose of circumventing the general carriers' reservations. There is a requirement that the same person be the principal user of adjoining distinct places before they can be aggregated into a single area for the purposes of installing a private network.

3.6 RESALE OF NETWORK CAPACITY

Under the Telecom Act, the unrestricted resale of network capacity acquired from a general carrier is permitted. Resale of network capacity may occur when telecommunications capacity is purchased from a carrier by a reseller who then sells the capacity to a third party. The capacity may be enhanced in some way to provide value added services or may be resold without change in its character to provide "simple" resale. Resale can be of both voice and non-voice capacity.

On September 19, 1991 AUSTEL issued a Service Provider's Class Licence which allows any person or organisation to acquire telecommunications capacity from a general carrier and resupply innovative services such as voice and non-voice services, private network services to consumer and commercial markets. A special feature of this Class Licence is that individual providers do not have to apply to AUSTEL for individual approval. Provided that the operators abide by the conditions and requirements of the Class Licence there will be a minimum of bureaucratic interference.

On November 26, 1991 a Ministerial Direction and Explanatory Statement on the resale of international capacity was tabled in Federal Parliament. The Government is conscious that there are some risks in unilaterally pursuing a liberal regime in respect of international telecommunications particularly if this could lead to foreign telecommunications operators operating under less liberal regimes being able to take unfair advantage of Australian carriers or service providers. Therefore the Ministerial Direction provides guidance to AUSTEL on the policy goals the Government wishes to be translated into conditions in a class licence in respect of the resale of international telecommunications capacity.

3.7 PUBLIC ACCESS CORDLESS TELEPHONES

AUSTEL has issued a class licence to allow public access cordless telephone services to operate in Australia. Public access cordless telephone services are similar to mobile phones except that calls can only be made within a range of 50 to 200 metres of base stations. Base stations are likely to be located at heavy traffic places such as railway stations, shopping centres and airports. It is expected that the cordless telephone services will be operated as radio-based public telephones with customers owning their own handset. By issuing a class licence public access cordless telephones will be open to full competition.

3.8 CUSTOMER EQUIPMENT

Section 253 of the Telecom Act provides that a person shall not connect to a telecommunications network customer equipment in respect of which a permit is not in force. Permits for customer equipment are granted by AUSTEL. Such permits are subject in some cases to compliance with the Government's industry development arrangements.

Section 17 of the Telecom Act makes it clear that equipment may be taken to be connected to a network whether or not it is in physical contact with the network if it is being used to supply telecommunications services by means of the network. As such the definition applies to equipment connected indirectly, such as computer equipment connected through a modem. However, under Section 267 of the Telecom Act AUSTEL may limit the provisions regulating customer equipment so as not to apply in relation to customer equipment of this type.

Under the Telecom Act it is an offence to sell or supply customer equipment to a person if there is no permit in respect of that equipment, without notifying the person that there is no such permit.

A general carrier is entitled to cease supplying a service to a person if there is connected to the network through which the services are provided customer equipment or customer cabling that is a threat to the safety or proper functioning of the network or the safety of any person.

Until July 1, 1991 Telecom had the exclusive right to supply the first phone - the handset, cord and plug - to all telephone customers. This right has been withdrawn and has significantly enhanced competition in the area of the supply of customer equipment.

4. RECENT SIGNIFICANT DEVELOPMENTS IN AUSTRALIA'S TELECOMMUNICATIONS INDUSTRY

4.1 SELECTION OF AUSTRALIA'S SECOND GENERAL CARRIER

As stated above, on November 19, 1991 the Government announced that Optus had been selected as Australia's second general carrier. Optus has agreed to pay the Government a total of A$800 million.

The timetable for service introduction by Optus is:

(i) 2nd quarter, 1992 - mobile cellular service marketing commences in every capital city. This service will be based on the resale of Telecom Mobilenet;

(ii) 4th quarter, 1992 - introduction of domestic long distance and international services available to Sydney and Melbourne;

(iii) early 1993 - introduction of new digital cellular services for mobile and personal communications;

(iv) 1993 - provision of value added network services for business.

4.2 PAY TELEVISION

The Government recently announced that the moratorium on pay television in Australia would be lifted. From October, 1992 at least four channels can be delivered on the Aussat satellite, with an additional two to be available for further development of pay television systems. The Government proposes that the multi-channel service will be delivered under a national licence that will be majority Australian owned. Existing free-to-air television licensors (including the Government owned Australian Broadcasting Commission) will be restricted to 25% ownership. Optus, as the new owner of Aussat, may take an equity share of up to 25%.

The Government has guaranteed that important programs, including national and international sporting and cultural events, will continue to be available on free-to-air television. This provision was introduced to alleviate concerns of opponents to pay television who feared that the general public would be denied access to national sporting events.

4.3 NEW SOUTH WALES GOVERNMENT'S PRIVATE NETWORK

The New South Wales Government has proposed the establishment of a New South Wales Telecommunications Authority which would have a virtual monopoly over New South Wales Government telecommunications. New South Wales Government bodies will be obliged to use the Authority.

The New South Wales Government proposes to bypass the Telecom Act by creating a single state-wide parcel of land which would have one title vested in the Authority and which would be used for the construction of the private network, separate to either Telecom's network or Optus' network. Pursuant to the proposal the space occupied by the network and a surrounding space of 300 millimetres would be vested in the New South Wales Government.

Under the Commonwealth Constitution the Commonwealth has legislative and executive power in respect of telecommunications. Therefore, if the Federal Government objects to the proposal it can legislate to prevent the creation of the New South Wales Government's private network.

5. CONCLUSION

Australia's new telecommunications regime significantly enhances competition in the Australian telecommunications industry in several fields. One of the major fields is the third mobile licence. As stated above, the decision to grant the third mobile licence will be made during 1992 with the licence effective from 1993. Another major field available is the grant of the pay television licence.

Other opportunities exist for telecommunications businesses in areas such as the provision of private networks, enhanced services and customer equipment. The issue of class licences allows businesses to enter certain fields with a minimum of bureaucratic interference provided that they satisfy the terms of the class licence.

It should be noted that the new telecommunications regime in Australia is evolving very quickly. For example between the date of writing this paper and the date of the Pacific Telecommunications Council Conference it is expected that the terms of the general carrier licence to be granted to Optus will be settled. Any existing or new participants in the Australian telecommunications industry should keep themselves.

Korea Telecom's Globalization Scheme in face of Restructuring of World Telecommunications Industry

Wan-Young YU, Ph.D.
Korea Telecom
Seoul, Korea

Sukbaum Pahng, Ph.D.
Chung-Ang University
Seoul, Korea

ABSTRACT

As the world telecommunications market liberalizes, new rules and orders are forming among nations and companies according to their comparative advantages. Believing that telecommunications is a futuristic business to continuous national growth and that those who fail to adapt to the competitive environment will eventually disappear, overseas business activity in this area to capture the world market has been increasing dramatically. As globalization accelerates, so does the restructuring of the world telecommunications market. The purpose of this paper is to define the proper roles and strategies of Korea Telecom under this rapidly changing market situation.

1. INTRODUCTION

Since the early 1980s, the world telecommunications industry has grown explosively. The industry is now moving toward state-of-the-art information business emerged by combining the traditional telephone operations based on analog technology with newly developed digital computer technology. As a result, new media appear everyday. This process is accelerating as the user's demands are becoming more and more complicated and diversified. It is also becoming obvious that the old, monopolistic and bureaucratic phone companies cannot be effective to cope with this rapid change. In this regard, there have been movements all over the world to introduce competition and deregulation in the telecommunications business. Believing that information industry be the mainstay of the futuristic society and that securing initiative in this industry lead to the prosperity of the nation, advanced countries have actively pursued free trade in this area through market openings.

Following the opening and deregulation of world market, major telecommunications companies in advanced countries compete to one another to take hegemony and to secure overseas presence. According to their comparative advantages, new rules and orders are forming in the world telecommunications market. This process is expected to continue in the 1990s. According to Mr. Ray Smith (1), Chairman of Bell Atlantic Co, any telecommunications company which could not secure its market presence in the world within the next ten years will disappear in the twenty-first century. Hughes et al. (2) also warn that, the destiny of telecommunications companies be determined by the degree of how much they prepare for the globalization.

> "As the telecommunications industry globalizes, the companies that fail to meet these early challenges will find themselves locked into domestic operations. They will face increasing competition at home and be unable to participate in the growth opportunities abroad."

On the other hand, compared to their recent economic success, developing nations maintain relatively old, insufficient telecommunications facilities, becoming a bottle-neck to the further economic growth. Like other infrastructure businesses, the expansion of network facilities require huge investment, which most of developing countries cannot afford due to their already debt-ridden budget. Besides, it is almost impossible to keep up with ever-changing new technology. They have no choice but to rely on foreign investors for their network expansion plan. Recently this has been creating ample international business opportunities in the world market.

Recognizing the international competition among advanced countries and new business opportunities in developing countries, Korea Telecom has been pushing its own two-stage globalization plan : The first stage of the plan (1980s) has been aimed at expanding network facilities, focusing on the quantitative growth of the company. When Korea Telecom was separated from the Ministry of

Communication in 1982, it operated only two million lines. Now it operates 15 million lines for a population of 42 million people and ranks ninth in the world in terms of subscriber lines. In 1986, the company developed a digital switch, TDX, with its own R&D team and became the tenth nation to possess such technology.

The second stage of the globalization plan (1990s) is directed toward the qualitative growth. Despite the substantial success quantitative-wise, more than 95% of its income comes from voice service, meaning that its business is not diversified at all. At this point, Korea Telecom is in a peculiar position between developed and developing nations. Quantitatively, it may be positioned as a developed, but qualitatively as an under-developed. The paper focuses on the second stage of the globalization plan and attempts to establish for the qualitative growth, and to define the proper roles of the company in face of restructuring of world telecommunications industry.

2. ESTABLISHMENT OF GLOBALIZATION SCHEME

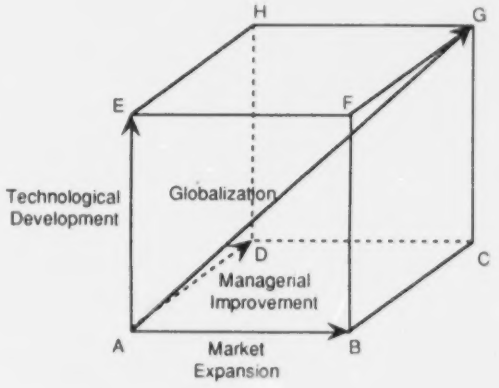
2.1 CONCEPT OF GLOBALIZATION

The term "globalization" is generally defined as a process of diffusing into overseas markets. That is, globalization is as an evolutionary process in which a domestic company begins to concentrate in export markets at first, then transforms itself to a multi-national corporation by shifting its managerial emphasis on overseas investment, and finally evolves into a global corporation whose business functions spread all over the world(3, p.20). This definition contains the concept of geographical expansion such as "a managerial activity happened across boundaries or occurred simultaneously in more than two countries."

However, this conception might not be applicable to Korean companies. Originally, the concept has been established by scholars of advanced countries modelled upon multi-national corporations. For example, when Korean companies pursue globalization, they often want to increase their competitiveness to the level of advanced countries, rather than to advance to overseas markets. In other words, the concept of globalization in Korea is recognized not only in the aspect, "global business activities in more than two countries," but also in relation to global competitiveness. From this viewpoint, globalization is possible not only through advancing to overseas markets, but also by technological development and managerial improvement to some degree. That is, advancing to overseas markets may not be the only mean to achieve globalization.

Likewise, when we interrelate globalization to global competitiveness rather than limiting it to geographical expansion, the concept may be defined in terms of three elements: technological development, managerial improvement, and market expansion (see Figure 1). These three elements strengthen the competitiveness at different levels: technological development at the level of possession of high-tech skills; managerial improvement at the level of rationalization and diversification of management; and market expansion at the level of economies of scale and market information. On the basis of this conception, globalization in this study is defined as "a process of strengthening the global competitiveness through technological development, managerial improvement and market expansion."

(Figure 1) Three Elements of Globalization



2.2 BASIC STRATEGY

In figure 1, there are several globalization paths to reach G from A (e.g., A→B→F→G). Depending on which path is selected, two distinctive types of globalization schemes may be derived. Figure 2 displays these two schemes on a two-dimensional space. Type I represents a market-oriented strategy, which first develops the overseas market with existing technology and managerial skills, later pursuing technological development and managerial improvement on the basis of market demand. Type II represents a technology-oriented strategy, which first puts emphasis on technological development and managerial improvement, later looking for overseas business opportunities.

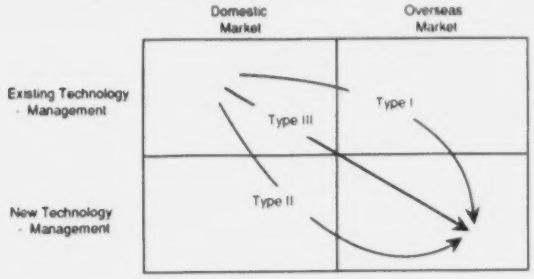
It may be controversial to determine which type is preferable. Those technologically oriented will insist

894

securing global competitiveness internally through technological development and managerial improvement believing that telecommunications in nature is a high-tech industry and hence, technological breakthrough creates new demands. This approach may be also effective to reduce foreign investment risk and technological/managerial disadvantages. On the other hand, those market-oriented will dispute that market expension should precede other factors, believing that global competitiveness can be achieved more effectively through direct competition with foreign companies in overseas markets. As Oettinger (4) points out, the direction of telecommunications industry shall be determined ultimately by users, therefore, demands on new technology and management be assessed through market analysis.

If we take the Korean auto industry as an example, Hyundai has preferred Type I strategy: Hyundai through which it has advanced to overseas markets first and has competed with foreign auto manufacturers existing skills. On the basis of the market experience from the competition, the company later carry out technological development and managerial improvement. However, Daewoo and Kia have concentrated on the internal competitiveness first through technological development and managerial improvement, and only recently begin to advance to American markets through OEM.

In this study, we recommend Type III strategy, an intermediate form between Type I and Type II, which pursues both market and technology at the same time, balancing the efforts. Although technology can broaden the scope of selection for users, the ultimate direction of telecommunications industry will be determined through the choice of users in the market. Therefore, both the technology and the market should be developed in a balanced and organic way. In this respect, Korea, positioned between advanced nations and developing nations, should pursue the market expansion and the technological/managerial development simultaneously, importing high-end technology from advanced countries, while advancing to the markets of developing countries with existing technology and managerial capacity.



(Figure 2) Basic Strategy

3. KOREA TELECOM'S GLOBALIZATION EFFORTS

Korea Telecom has already activated several domestic as well as international programs to improve its quality as a part of second stage globalization plan.

3.1 DOMESTIC ACTIVITIES

(1) The company is expected to go public in 1992.

(2) A new corporate culture is programmed to boost the morale by integrating three elements - information, telecommunications, and human being (5).

(3) The company has initiated a CIP (Corporate Identity Program) and more of customer-oriented managerial approaches.

(4) Several new ventures such as satellite, CATV, software development, information service, etc. are explored to diversify its business and to learn the technology.

(5) Since 1991, the company has changed its name from Korea Telecommunications Authority into Korea Telecom (KT) to build a privatized, high-tech company image.

3.2 INTERNATIONAL ACTIVITIES

(1) ***Expanding Overseas Liaison Offices***: Korea Telecom operates five liaison offices in Washington D.C., New York, Geneva, Bangkok and Tokyo. At present, these offices are mostly used as contact points for foreign carriers, but in the future, their roles and functions will be enhanced to be used as bridgeheads in the overseas business.

(2) ***Supporting telecommunications technology to other developing countries***: Korea Telecom has provided education and training programs on electronic exchanges to ten developing countries including Thailand and the Philippines since 1984.

(3) ***Construction of international submarine cable system:*** As a part of globalization plan, Korea Telecom has actively participated in international construction projects of telecommunications facilities to secure permanent lease of the proposed international transmission routes. The TPC-3 project connecting Japan, Guam and Hawaii (completed in 1983, 15 countries), the HAW-4 project connecting Hawaii and the US, the GPT project connecting Guam, the Philippines and

Taiwan (completed in 1988, 13 countries), the H-J-K project connecting Hong Kong, Japan and Korea (completed in 1988, 14 countries) and the TSL (Trans-Siberian Lines) project are good examples of such efforts.

(4) ***Cooperation with other telecommunications carriers:*** Another important strategy of Korea Telecom is to progressively expand the cooperative relationships with other phone carriers through signing of memoranda of understanding (MOUs). Since signing of MOU with KDD of Japan in 1965, Korea Telecom has exchanged MOUs with 18 carriers from ten countries including the US, France, Spain, Hong Kong. To support "northern policy" of the Korean government, Korea Telecom has signed MOUs with East European countries including Hungary. It also tries to maintain close relationships with EC countries through enhanced cooperative activities and joint development of technology, etc..

(5) ***Overseas business:*** Korea Telecom's overseas business activities is at a preparation stage to test the possibility and to capture the international business experience. At this point, Korea Telecom is taking a very conservative approach to reduce the high investment risk. Therefore, most of the activities are small-scaled, sporadic and in many cases, not pre-planned.

Korea Telecom's overseas business for market expansion includes a couple of management and technology consulting projects - the Twinning program in Indonesia to assist the phone service upgrade and the network expansion in the country, and the Barcelona project to help the construction of telecommunications facilities for the 1992 Olympic. Korea Telecom is also actively pursuing the EABC (Euro-Asia Business Center) project in Netherlands and the network expansion project in Indonesia. For the import of advanced technology, the company has been evaluating several projects including the investment in the USL (Unix System Laboratories) share holdings.

4. KOREA TELECOM'S ROLES IN THE WORLD MARKET

4.1 RESTRUCTURING OF WORLD TELECOMMUNICATIONS INDUSTRY

Recently, the world telecommunications community has been forming, centered around three blocs - "the U.S.," "Japan" and "Europe including the U.K."

Telecommunications carriers from these nations are the most actively engaging in the globalization and advancing to the overseas markets. In the U.S., the Bell Atlantic Co. plans to make 10% of its total revenue from overseas business by 1995. It has acquired New Zealand Telecom and has participated in mobile phone projects in Czechoslovakia and Italy.

AT&T plans to increase its overseas revenue from 15% to 25% by 1995. For this purpose, AT&T has cooperated with European carriers and manufacturers including Philips, Olivetti and Italtel to advance to European markets and, lately, acquires NCR, an internationally-known computer company, to secure world markets (6).

NTT's overseas business activity is sluggish compared to their U.S. and European counterparts due to their restrictive domestic law. Yet their technology is state-of-the-art, directed toward VI&P (Visual, Intelligent, and Personal) communications (7).

In Europe, British Telecom has participated actively in the international value-added network (IVAN) operations by acquiring Tymnet and Dialcom of the US, to increase the revenue from overseas business from 10 ~ 15% to 20 ~ 25%. France Telecom is also advancing to the IVAN markets of Europe and North America and intensifying the marketing of Minitel services internationally. France Telecom also plans to increase the revenue from overseas business to 10% before the turn of this century. Telefonica of Spain and STET of Italy have also advanced to markets of South America, including Chile and Argentina, and East European countries. Likewise, present world telecommunications market is becoming a battlefield of world telecommunications carriers, fighting for the initiatives in the overseas market.

On the other hand, Indonesia, Columbia, East Bloc, and other developing countries are looking for foreign investors to expand their network facilities. This network infrastructure expansion requires heavy investment that foreign debt-ridden developing countries cannot afford. Insufficient network facilities are becoming a bottleneck to the successful implementation of continuous economic growth.

To attract foreign investors, A BOT (Build, Operate, Transfer) type project is often offered in which foreign investors finance, construct, operate, and transfer to the host country after realizing a sufficient return. Developing Countries prefer this method, since they can own network facilities after a certain period of time without hurting their foreign-debt situation and also they have a chance to learn efficient management skill. Sometimes, in order to make the project more attractive, foreign investors are allowed to maintain a limited ownership of the installed network facilities, called BOO or BOM project. Thailand has been

successful to host BT and CP, a Thai company, for its expansion plan with a BOT-type approach. Indonesia is currently offering a similar project.

Yet the BOT project may not look that much attractive from the investors' viewpoint due to a long return period compared to its heavy investment. For the hosting countries, the maintenance of the facilities is also very costly and besides, ever-changing new technology is hard to keep up with. In this regard, several countries offer the sales of their main phone carriers (e.g., New Zealand, Mexico, Venezuela, Puerto Rico, etc.) with some requirements specifying a certain level of network expansion, service improvement, and investment amount by foreign investors. These ample business opportunities in developing nations as well as fierce competition among advanced countries are creating new rules and orders in the world telecommunications industry.

4.2 KOREA TELECOM'S ROLES

Korea Telecom operates 15 million lines for a population of 42 million people and ranks ninth in the world in terms of subscriber lines. Yet more than 95% of its income comes from voice service, meaning that its business is not diversified at all. Quantitatively, Korea Telecom may be positioned as a developed, but qualitatively as an under-developed company.

As discussed earlier, Korea Telecom has focused on the quantitative growth in the 1980s during the first stage of the globalization plan. In the 1990s, during the second stage of the plan, the company's emphasis will be moved toward the qualitative growth in the directions of technological development, managerial diversification, and market expansion into the world. This ambitious plan may not be possible without the technological and managerial assistance from the advanced nations. In this connection, Korea Telecom and the telecommunications market in Korea will provide one of the most attractive business opportunities for the advanced countries in the areas of enhanced service, softwares, technological/ managerial consulting, and etc.

On the other hand, Korea Telecom can satisfy the needs of network infrastructure expansion in developing nations. In addition to its very efficient skills enough to install 2.8 million lines in 1990 alone, the company has comparative advantages compared to advanced companies in the construction of network facilities.

(1) ***Proper level of technology :*** What the developing countries require is not a hard-to-learn, state-of-the-art technology of advanced countries. They would rather prefer labor-intensive technology which is pertinent to their technological level and has considerable effects on employment of local population.

(2) ***Flexibility of market scale:*** Markets of the developing countries are usually small and have large price elasticity of demands. Accordingly, Korea Telecom has some advantages because it can provide services at elastically low prices on a flexible scale.

(3) ***Compensation to expatriates:*** Telecommunications carriers of advanced countries have to pay fairly high compensation and incentives to their staff to send them to developing countries. They also have difficulties in finding well-qualified volunteers.

(4) ***Supply of telecommunications equipments:*** Korea Telecom has some advantages because it can supply high-quality telecommunications equipments at comparably low prices through Korean manufacturers.

(5) ***Similarity in political, economical and cultural environments:*** Especially, Southeast Asian countries and Korea have similarities to one another in political, economical and cultural environments. These countries are also precautious against the expansionism by some advanced countries.

Korea Telecom is in a peculiar position between developed and developing countries. From the developed, Korea Telecom needs to learn the advanced technology and managerial skills for its qualitative growth. That is, the company as well as the telecommunications market in Korea are providing attractive business opportunities for the developed. For the developing, it can contribute to the expansion of network infrastructure on the basis of its experience gained from its successful quantitative growth in the 1980s.

In conclusion, Korea Telecom should serve to bridge the gap between developed and developing nations in the world telecommunications industry with the spirits of cooperation and coexistence.

An Exercise in Privatization: The Making of Telekom Malaysia

Baharuddin Aziz
MARA Institute of Technology
School of Communication
Shah Alam, MALAYSIA

1. ABSTRACT

The privatization of Malaysian government-owned and operated public services was a major aspect of the development agenda since the early 1980's. It was generally perceived by policy makers as the sine qua nom of the country's economic growth and the future development. Among the services initially earmarked for privatization were the transport and telecommunication sectors. This article takes a retrospective look at the Malaysian government's privatization policy with respect to the formation of Telekom Malaysia and explores the current and future telecommunication scenario vis-a-vis the biggest public-listing exercise in Malaysia's corporate history.

2. INTRODUCTION

An advertisement which regularly appears in Utusan Malaysia, a leading Malay-language daily, features a *tabib* (practicioner of traditional Malay medicine and other means of sex therapy) publicizing his services which purport to guarantee enhancement of men's sex life and general health. This particular advertisement would seem ordinary except that it carries the picture of the *tabib* clutching a cordless phone close to his ear. One can easily get this picture of a high-tech traditional medicine man at work. Blessed with this new sophisticated mobile phone, men from around the world, especially those afflicted with problems of a sexual nature, can now contact him almost instantaneously.

The above example reflects the vital role modern telecommunication plays in the day-to-day affair of the average Malaysian both in his private and public life. Even street hawkers nowadays take orders from their regular customers with the aid of mobile phone sets. And it is not uncommon especially for businessmen to be equipped with hand and/or car phones.

Indeed, with each passing day, new innovations accompained by a good measure of excitement, seem to color Malaysian telecommunication. Notwithstanding the availability of new and improved value-added services such as MAYCIS (Malaysian Circuit Switched Data Network) and MAYPAC (Malaysian Packet Switched Public Data Network), Telekom Malaysia's data communication services to commercial enterprises, *Telita* (videotext transmission), itemized customer billing and mobile telephony, last year (1991) witnessed events promising even bigger strides in the country's telecommunication development. Among them are:

i) The signing of the memorandum of understanding (MOU) held on the island of Langkawi which will pave the way for the launching of Malaysia's very own geosynchronous satellites in 1994. The satellites, known as Measat (or Malaysia East Asia Satellites) and costing U.S $250 million, are owned and operated by Binariang Sendirian Berhad, a Kuala Lumpur-based company. Built by America's Hughes Communications International Inc., Measat's satellites are expected to be launched in 1994 off Kourou in French Guyana by Arianespace of France;[1]

ii) The launching of the second phase of Telekom Malaysia's pilot ISDN (Integrated Services Digital Network) project. Initially to cover the populous Klang Valley in Peninsular Malaysia, ISDN systems are expected to be operational on a commercial basis in 1993. With the availability of ISDN -- where digitized voice, data text and images can be communicated via a single line -- Malaysia is poised to become the third country in Asia after Japan and Singapore to provide such sophisticated circuitry;[2]

iii) The completion and launching of a submarine optic-fibre cable link between Kuantan on the east coast of Peninsula Malaysia and Kota Kinabalu in East Malaysia. This optical-fibre link is expected to enhance the quality of telephone and broadcast transmission links between East and West Malaysia and support new services.[3]

The events, each a milestone in the development and expansion of telecommunication infrastructure and services in Malaysia, were largely viewed as being the manifestation of the deregulation and privatization policies adopted by the government in the early eighties in so far as the telecommunication sector is concerned. Deregulation of the telecommunications environment had also provided impetus for and entry of locally incorporated as well as foreign-based companies to compete for a slice of certain telecommunication services like pay and credit-card phones, mobile telephony, and paging systems. Competition among the telcos and having market forces decide their fortunes have generally brought about increased efficiency on the part of the telcos, enhanced their productivity and outlook, apart from sensitizing their staff to the importance of maintaining high-level customer satisfaction.

Rapid advancement in state-of-the-art telecommunications technology in the last two decades also dictated that the Malaysian government revamp the administrative structures and management function of Jabatan Telekom Malaysia (JTM), Telekom Malaysia's predecessor. JTM was the government department in charge of providing and upgrading telecommunication services and maintenance of infrastructure nationwide. Encumbered with administrative procedures and regulations, it was generally felt by policy makers that, as a government department, JTM would be in no positon to provide a viable network let alone run a profit-oriented telecommunication service for to the country.

Besides the rapid advancement of telecommunication technology, there were other conducive factors enabling the privatization of telecommunication services in Malaysia. These will be discussed in the following section.

3. PRIVATIZATION: THE BEGINNING

The impetus for the privatization of government-owned and operated public services had largely come from Malaysian Prime Minister Dr. Mahathir Mohamad when he assumed the mantle of leadership in 1981 from former Prime Minister Hussein Onn when the latter stepped down due to healt reasons. Dr. Mahathir initiated a series of Policy changes--often viewed as drastic by some at that time and with skepticism by his detractors--viz his Look East policy, emphasis on heavy industries, Leadership by Example and, of course, privatization coming almost simultaneously with the push for industrialization and export-orientation. Although critics had expressed reservations saying that "nepotism and corruption" can easily rear their ugly heads if privatization is not executed according to the book and done openly, it is generally felt that the majority of Malaysians do not want privatization stopped altogether as many consider their state-owned and run utilities inefficient.[4]

Ailing government corporations and obligations on the government's part to finance and provide for certain public services put a strain on the country's finances. The corporatization and, later, privatization, of these government entities were recognized as possible options to relieve the government of its financial burden and resuscitate some of its financially-strapped corporations and utility providers. Futhermore, the onslaught of recession in 1983 convinced the Mahathir Administration that the private sector should be accorded a bigger role in the provision of social services and amenities to the nation and hence reduce government expenditure on such services.

The Cabinet entrusted the Economic Planning Unit (EPU) of the Prime Minister's Department with the task of coming out with a comprehensive national privatization masterplan, one in which the government envisages should: "...enhance the role of the private sector in the economy while at the same time creating new opportunities for the public, in particular the employees of the privatised projects as well as the Bumiputera community to own wealth through the purchase of shares in these projects".[5]

3.1 PRIVATIZATION AND THE ROLE OF EPU

Privatization, by the end of the 1970's, was becoming an international catch-cry and Malaysia, which did not lose time in recognizing it as an instrument for spurring economic growth,

coopted it into its development agenda. The Economic Planning Unit (EPU) of the Prime Minister's Department set to work out the best possible privatization formula that took cognizance of the country's development goals and immediate priorities. Based on an analysis of two EPU publications focusing on the implementation guidelines of the policy,[6] privatization's major guiding principle can be summarized as follows: provision of strategic services in an efficient, profitable manner but without sacrificing public needs and/or, more importantly, jeopardizing the interests of the ruling political party.

Identification by the EPU of potential candidates for privatization got undersay in 1982. Among the earliest to be identified were the Malayan Railway, the Port Klang Container Terminal, National Padi and Rice Board's rice milling complexes and the Royal Malaysian Navy Dockyard located in Lumut. This was followed by the moves to corporatize and then privatize the National Electricity Board and Jabatan Telekom Malaysia. Up till the end of 1991 and since the formal implementation of the privatization policy in 1983, 37 projects have been privatized, 27 of which were once government entities but now taken over by private companies either through outright management buy-outs or by sale of equity or assets to the public. The government earned $U.S.437 million through sales of its interests in entities which it once owned and was financially relieved of some $U.S.3 billion when it need no longer has to foot the bill for costs of infrastucture development and operating expenses.

The EPU subscribes to two other basic types of privatization implenentation methodology: "Build-Operate-Transfer" (BOT) and "Build-Operate" (BO). The BOT concept requires interested companies to submit proposals. If approved, the company then constructs the facility with its own funds but is allowed to collect revenues from users over a specific period of time. The construction of highways and collection of toll is an example of this. The BO scheme is largely similar to BOT but the company concerned does not transfer its assets or facility to the government. An example of BO is Sistem Televisyen Malaysia Berhad (STMB). Granted a license by the Ministry of Telecommunications, Post and Energy in 1985, it now operates a private commercial TV station (TV-3) nationwide. STMB's ownership, however, is closely linked to the investment arm of UMNO or United Malays National Organization, the major component of *Barisan National*, the ruling calition, as well as, to other organisations linked to the other leading political parties in the coalition.

Besides recommending government entities for possible privatization to the Cabinet, the EPU also reviews proposals from various private companies keen to take over state-owned and operated entities. The process, as illustrated in Figure 1† also at times involves the appointment of consultants to undertake a feasibility study once a proposal is submitted via the EPU to the Cabinet. Based on consultants' appraisals and recommendations, the Cabinet would then seek passages of legal amendments to existing statutes like the Pensions Act of 1980, the Telecommunications Act of 1950 and the Electricity Act of 1949 so as to facilitate the smooth transfer of government, assets and the profitable management of services by private companies that are established under the Companies Act of 1965.

Proposals to buy out or take over the running of state-owned services must take cognizance of the objectives of Malaysia's privatization policy, viz

a) relieve the financial and administrative burden of government;

b) improve efficiency and productivity;

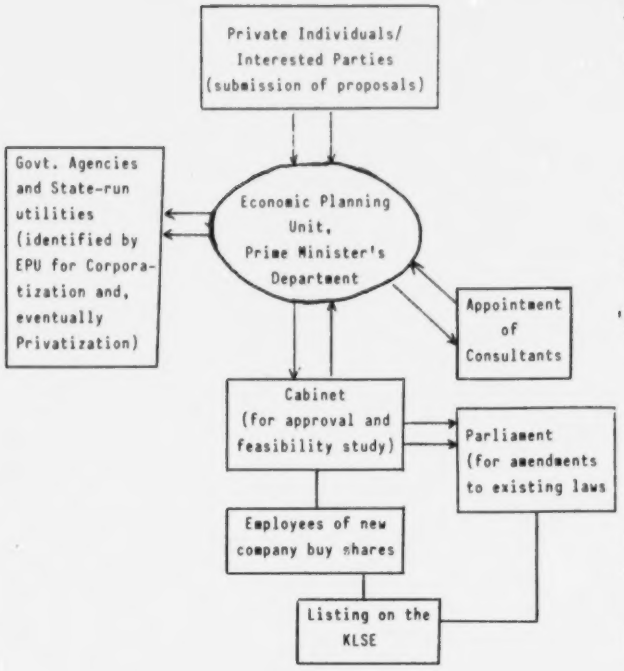
c) facilitate economic growth;

d) reduce the size and presence of the public sector in the economy; and

e) help meet the national economic policy targets.[7]

Reflective of the policy objective as mentioned in (e), privatization also is seen as an instrument to enhance Bumiputera (indigeous) equity stake and increase their participation in the corporate sector. Apart from this, employees of newly-privatized entities will stand to gain from higher remuneration and benefits concomitant to the implementation of various incentive schemes which otherwise are not usually found in government enterprises. They can own a part of the company through such schemes as the Employee Share Ownership Plan (ESOP) and Management-Employee Buy-Outs (MEBOs) as prescribed in the privatization masterplan.

(*See next page)



Steps in the Privatization Process

1. Identification by the EPU of state-owned and run utilities and services for possible privatization;
   Proposals submitted by interested parties to the EPU.
2. Analysis, Review and Recommendations by EPU to the Cabinet.
3. Cabinet approval; appointment of consultants.
4. Cabinet proposes new laws and amendments to existing statutes for passage by Parliament.
5. New company/corporation set up under the Companies Act of 1965 to take over ownership/management of state-owned and operated agencies/utilities.
6. Sale of shares to Employees.
7. Prospectus and sales of shares to the public.
8. Listing on KLSE.

Fig. 1 Major Entities and Steps in the Privatization Process

As for foreign ownership, certain conditions prevail, particularly in terms of the value and amount of equity held in a company, which must not be in the majority. Foreign ownership is allowed only if its:

a) expertise is needed to upgrade efficiency and such expertise is not available;

b) participation is necessary to promote the export market;

c) purchase of shares will help supplement the supply of local capital; and

d) participation will enhance global linkages and international exposure.[8]

The next section takes a look at the biggest transfer exercise of public assets and services to a largely government-owned company as well as the largest public listing in Malaysia's corporate history. It also offers a brief assessment of Telekom Malaysia's performance besides exploring the company's prospects in the near future.

4. TELEKOM MALAYSIA: PERFORMANCE AND PROSPECTS

The Malaysian telecommunications environment was poised to enter a new era of growth and expansion when, in 1987, the government transfered JTM's assets and operations to a corporation known as Syarikat Telekom Malaysia (STM).[9] The transfer not only hightened public expectations at home, it also attracted the attention of foreign investors. Malaysians, not unlike the foreign investors, expected an overall improvement to their telecommunication services, albeit, shorter waiting periods for telephone installations.

Apart from this, an important pre-requisite to more foreign investments into the country, the government knows, is an efficiently-run and up-to-date infrastructure and related services. The desire to enhance connectivity to the transnational corporate structure and the international marketplace meant the creation of a carrier unshackled by cumbersome government procedures and capability to keep pace with modern information and communication technology.

992

Hence, the inertia to inevitably privatize JTM.

4.1 FLOTATION OF TELEKOM MALAYSIA SHARES

After three years of "corporatization" characterized by steady growth, STM was ready to have its shares listed on the Kuala Lumpur Stock Exchange (KLSE).[10] A total of 470.5 million new ordinary share--representing 23.8% of the corporation's issued and paid-up capital--was floated in September 1990. The issue price was M$5.00, or roughly $U.S.1.80, which was thought to be fairly high for an introductory issue. At the end of the day, the sale of its shares was oversubscribed by only 1.5 times, a figure far below what industry analysts had expected. Hesitations were largely blamed on uncertainties in the Middle East (Iraq's invasion of Kuwait) and Malaysianstypically saving up for incidental end-of-year expenses.

In line with the government's policy of increasing indigenous equity stake, Telekom Malaysia reserved slightly more than 30% of the issued shares to Bumiputra-related institutions and individuals. Five-percent were allocated to foreigners while another 15% were meant for its employees and eligible employees of JTM. Through what was known as "pink forms", employees, nearly all of whom had opted to serve with Telekom Malaysia, were privileged to purchase their company's shares. Almost all did but some resold them in order to make quick gains when Telekom Malaysia share price went up to U.S.$2.40 per unit on the KL bourse. This unforseen behavior on the part of the employees later led to the Economic Planning Unit to coopt the Employee Share Ownership Plan (ESOP) to its privatization policy. ESOP involves the setting up of a trust to hold shares for employees. Under such a scheme, employees can only sell their shares when they leave the company or when they retire.

Based on Telekom Malaysia's 1990 Annual Report, the government of Malaysia, through a body corporate established under the Minister of Finance (Inc.) Act, 1957, holds 76% or close to 1.5 billion of Telekom Malaysia shares while, individuals from Malaysia make up 3.3% of the shareholders, and foreigners 3.7%.
(see Appendix 1)

4.2 TELEKOM MALAYSIA'S PERFORMANCE: AN OVERVIEW

If profits are any measure of Telekom Malaysia's performance, then the telecommunication behemoth is, indeed, a succeess story. Telekom Malaysia has in the last three years been viewed and recognized as a national phenomenon; the flagship of the government's privatization policy. Figure 2 indicates the extent of Telekom Malaysia's steady gains in its pre-tax profits since corporatization in 1987. Since then, the government has, as an incentive, not taxed Telekom Malaysia earnings and this, analysts say, was one stabilizing factor of the company's share price on the KLSE. Once an actively-traded counter, Telekom Malaysia share price rose to a high of U.S.$4.50 in May 1991 only to ease off at U.S.$3.70 at the end of the year, far below that of U.S.$7.40- a price analysts predicted the shares could fetch but never did. Nonetheless, the company expects to achieve a pre-tax profit of U.S.$370 million for 1991.[11]

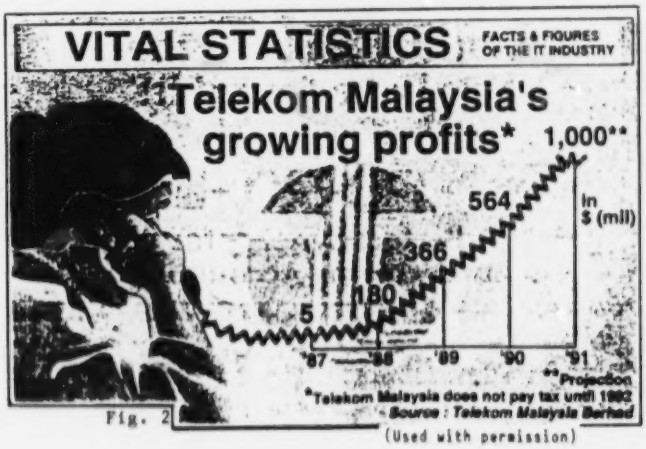


Fig. 2

Notwithstanding the availability of an array of digitized data communication services as well as domestic and international toll-free dialing, waiting period for phone installation has also been cut from six months to roughly two weeks since the company's inception in 1987. Telephone density per 100 inhabitants, too, has risen from 6.8 in 1982 to 9.2 in 1991. With steady increases in line installations, the company expects to increase density to 25 by the year 2000, thereby inching Malaysia closer to the ratio achieved by developed countries. Hopefully, services, expecially residential telephones, will be equitably spread nationwide.

As for now, telephone density and various other value added services are concentrated in major cities. Those in rural areas (where density is two per 100 inhabitants) often complain of difficulties of access to good, working telephones. Despite the shortcomings, it is, however, heartening to note that Telekom Malaysia is setting aside U.S.$630 million to expand and upgrade rural telephony during the Sixth Malaysia Plan period (1991-1995). And over the same period, too, about U.S.$3.70 billion worth of capital investments will be made mostly by Telekom Malaysia to upgrade and maintain telecommunication's infrastructure in Malaysia, making it one of the fastest and largest growth market for telecom equipment in the Asia-Pacific region.[12]

5. CONCLUSION

We are said to be moving into the Information Age--an era characterized by the synergy of tele-communication technologies and computers continually transforming the manner, speed and volume by which data, voice and images are communicated across the globe. The rapid advancement in communication and information technologies especially in the last two decades had necessitated a re-examination of policies both in developed and developing countries and the fine-tuning of regulatory frameworks governing their use.

In Malaysia, apart from the rapid advancement in telecommunication technology, other factors spurred the privatization of the country's telecommunication services:

i) the need to enhance connectivity to the transnational corporate structure and the global marketplace,

ii) government's own need to relief itself of the burden of expenditure on public utilities,

iii) the need to raise indigenous ownership of the corporate wealth of the country.

One of the bigger challenges to Telekom Malaysia in the course of its privatization is the maintennance of a proper balance between an efficiently-run, profit-oriented company and commitment to social needs and public interest. As for the former, Telekom Malaysia has proven itself reasonably well judging from:

i) steady increases in profits made since its inception,

ii) its shares are actively traded and are viewed by industry analysts as growth utility stock and

iii) its ability to settle outstanding loans particularly from the 1990 floatation exercise.

As for meeting social needs, much is left to be desired. Rural telecommunications is in dire need of improvement let alone expansion and much of the advanced services are urban-centered, mostly catering to the needs of the mercantile community. However, the educational sector is neglected and it is felt that Telekom Malaysia should chart a more visible and active role toward enhancing education via use of its own array of telemedia delivery systems. Academicians in the country feel that the new video teleconferencing facility which Telekom Malaysia plans to introduce in the foreseeable future will cater more to the needs of the corporate world. What is needed is close cooperation between Telekom Malaysia and institutions of higher learning so that a strategic plan could be worked out for effective utilization of its systems in order to enhance distance learning and telelectures by videoconferencing and production of knowledge-based software.

In their study of ASEAN's telecommunication policies and trends in infrastructure development, Hukill and Jussawalla (1991) felt that network expansion is bound to put pressure on traditional culture as Westernization gets the better of the Malay/Muslim values and this could be destabilizing to Malaysia's multiracial polity![13] While this may be a legitimate concern but this writer, going to the story of the *tabib* with which he began this paper, is inclined to believe that what is important is the harmonious blending of modern technology and the utilization of new information and communication technologies to suit local needs and values. The case of the *tabib* traditional Malay medicine man serve to illustrate this point.

With expanded networks and the globalization of telemedia delivery systems, Telekom Malaysia should cooperate more closely with the local entertainment and cultural industry and play a pivotal role to balance out the flow of cultural, knowledge and information-based product--which

have always been in favor of the developed Western countries--at least within the Asia-Pacific region.

The telecommunications sector in Malaysia is poised for further expansion as the nation's economy continue to show signs of stable growth. Telekom Malaysia is expected to play a pivotal role in the nations economic development as the nation aspires to become a significant player in the international marketplace and achieve developed country status in the year 2020.

PRIVATIZATION OF TELECOMMUNICATIONS FACILITIES IN THE PHILIPPINES

R.I. de Vera, Undersecretary Department of Transportation & Communications, Republic of the Philippines

C.H. McGlone, Telecommunications Consultant for the United States Agency for International Development, Manila, Philippines

R.L. Rothery, Vice President Operations, Teleconsult Ltd., Canada

1. ABSTRACT

Policies of the Philippine Department of Transportation and Communications recognize the private sector as the key to development of the telecommunications sector. This paper overviews the experiences of the Philippines in their first privatization exercise of telecommunications facilities. The paper describes the unique aspects of the telecommunications sector in the Philippines and the objectives of the government in establishing a privatization program. It also addresses related issues of funding, of support to private companies and of transferring facilities to a private sector characterized by a dominant operator and a number of small operators.

2. THE PHILIPPINES TELECOMMUNICATIONS SECTOR

The current telecommunications infrastructure displays an imbalance in the distribution of telecommunications facilities which leads to services that are concentrated in Metro Manila, selected cities and urban centers in the country. On the national level there are only 1.6 telephones per 100 people while in Metro Manila the development is 9.6 telephones per 100 people. There are 920,000 telephones installed with approximately 80% located in the Metro Manila area and the remaining 20% distributed in other municipalities. Telephone service is inadequate and of poor quality especially in the countryside. Characteristically, there is an inability of the private and public sector to obtain attractive financing to fund the required network construction and the much needed service improvements.

The Philippine Long Distance Telephone Company (PLDT) currently dominates the industry with approximately 95% of the market share. An additional 67 private companies are interconnected to PLDT's network. A number of other operators provide non-interconnected services.

The Department of Transportation and Communications (DOTC) is the government agency responsible for formulating national policies pertaining to the development of telecommunications systems in the Philippines. DOTC implements plans and policies through the National Telecommunication Commission (NTC). All domestic and international telecommunications services are governed by DOTC directives and pronouncements. In particular, DOTC is empowered to formulate and recommend national policies and guidelines for the preparation and implementation of an integrated and comprehensive communications system at the national, regional and local levels.

The National Telecommunications Commission (NTC) is the agency within DOTC which carries out the DOTC policies and responsibilities. The NTC supervises, regulates and controls all telecommunications services in the country including approval and supervision of all expansion and modernization projects, regulating private investment in telecommunications equipment and systems, setting and enforcing rates and technical standards, allocating frequencies and issuing operating permits. The NTC has quasijudicial powers which can only be appealed to the Supreme Court. NTC is also empowered to exercise supervision and control through its organizational units and regional offices.

The Telecommunications Office (TELOF), a government agency created under DOTC, is the chief operating agency of the government for telecommunications. Its main functions are: (a) To develop, formulate and recommend plans, policies, programs, standards, specifications and guidelines for providing telecommunications facilities including telecommunications systems for purposes of augmenting limited or inadequate existing private telecommunications service; and (b) To provide telecommunications services in areas

where no such services are available. TELOF's main operations are a nationwide telegraph system and 27 rural exchanges.

3. THE PRIVATIZATION PROJECT

3.1 BACKGROUND

The Telecommunications Policy Directorate (TPD) of the Department of Transportation and Communications (DOTC) has undertaken to implement policies which recognize the private sector as the key to development of the telecommunications sector. An important element of this policy is Department Circular 90-252 which mandates the ultimate privatization of all government owned facilities.

A first initiative in this area was the privatization of Phase A of the Rural Telephone Development Program RTDP(A). Subsequently, further privatization efforts were identified for Phase B (RTDP-B) and Phase I, Tranche 1 of the National Telephone Development Program (NTPI-1).

RTDP(A) is an operational system providing 11,000 lines and associated exchange and toll services to subscribers in northern Luzon. The system is owned by the government and operated under contract by a private company, Filphone. RTDP(B) will add 8000 lines to the RTDP system, while NTPI-1 will provide approximately 50,000 lines and associated toll facilities in regions 3 to 5.

The Regional Telecommunications Development Project and the National Telephone Development Program were conceived by the Government of the Philippines with the primary objective to correct the disparities in the local socio-economic status between the rural and urban settlements and to uplift conditions in the rural areas of the country through effective communications systems. Both the RTDP and NTP facilities were funded through the Overseas Economic Cooperation Fund of Japan.

3.2 OBJECTIVES

At the outset, the government established these objectives for privatization:

a) To improve the financial return to government over what it would realize from operating the facilities through a government agency.

b) To ensure viability of the operator who eventually acquired the facilities.

c) To encourage service expansion after the transfer of facilities.

d) To encourage the long term modernization of equipment and provision of new services.

3.3 ORGANIZATION OF THE PRIVATIZATION PROJECT

The organization, adopted by the DOTC to carry out the privatization project, is illustrated in Figure 1.

DOTC Prequalification and Award Committee: This Committee is comprised of Senior DOTC officials along with a member assigned from a nonGovernment industry association. Under Philippine law, the committee is an officially designated body which defines the terms of reference for a project, oversees the prequalification of prospective bidders and is ultimately responsible for the review and selection of the bids.

Advisory Group: An advisory group with representatives from the Philippine Association of Private Telephone Companies and the National Telecommunications Commission (NTC), advised on the criteria for prequalification and other matters such as the rationalization of exchange serving arrangements.

Subcommittees: The DOTC financial and technical subcommittees developed the prequalification procedures and methods for the evaluation of submissions. In addition, the working subcommittees did the actual evaluation of the financial, technical and management bid submissions.

Consultants: Consultants were provided by the United States Agency for International Development (U.S.A.I.D.) and the Asian Development Bank ADB.

3.4 WORK UNDERTAKEN

The privatization work began in mid 1990 when the DOTC formally announced its plans to divest of all of its telecommunications operations. RTDP (A) was identified as the first system to turn over to the private sector. The RTDP (B) and NTP I-1 were soon added. Following is a brief description of the work undertaken to date by DOTC:

Prequalification: DOTC, with input from industry and the NTC, established criteria for companies to take over the government owned systems. Submissions were solicited and the DOTC received responses from 8 companies. 5 companies were prequalified. The basis of prequalification was the demonstrated financial and technical capability of the companies to assume operation of the government systems. Regulatory authorization was not a requirement.

Asset Valuation: A detailed asset valuation was carried out on the RTDP (A) facilities, which included estimations of replacement cost and depreciated value. A detailed field study was not conducted of RTDP (B) and NTP I-1 as these systems were not yet installed. However, information was gathered from the contracts for these systems on the quantities and types of equipment, and on the value of these systems.

Financial Strategy: A report was prepared which outlined the options for sale and lease of assets. The report presented different lease structures of upfront payments, revenue based payments and capacity based payments. The intent of the report was to present the benefits of various options to DOTC as an input to structuring the bid documents.

Development of Bid Documents: Bid documents were produced instructing bidders on the content and structure of bids to be submitted to DOTC. The documents included bid instructions and requirements, a description of the assets being bid, a proforma contract, operational and technical requirements to be assumed by the successful bidder, and the required structure of their financial proposals.

Asset Value/Cash Flow Analysis: Two studies were undertaken to assess the value of the facilities being bid. The studies took two approaches. One approach assessed the fair market value of the assets. The second approach calculated the net present value of the expected excess cash flow from private operation of the system (as compared to government operation). The studies tested various sensitivities such as economic life, discount rate, revenue growth and operating efficiency. The studies were the main input to establishing a "floor price", the minimum bid offer, acceptable to DOTC.

Bidders Conference: A conference was held immediately following issuance of the bid documents. Prospective bidders were invited to comment on the bid documents and seek clarification of the bidding process. The conference was followed by a formal written response from DOTC to all bidders which provided additional information on the issues raised at the conference. In addition, a technical working session was arranged following the conference. At this session, technical representatives of the bidders were provided with system drawings, equipment lists and other technical documentation held by DOTC which could assist bidders in preparing their bids.

Bid Evaluation: Four bids were received. The technical and management proposals were evaluated by the Technical Working Committee according to predetermined evaluation criteria. They found all proposals to be compliant and recommended acceptance to the committee. The financial proposals were evaluated after completion of the technical evaluation and following a public opening of the financial offers. The financial evaluation was undertaken to confirm that there were no errors in calculation or misunderstanding of the financial offers of the bidders. Two companies submitted bids which exceeded the minimum acceptable price established by DOTC (the "floor price"). As of this writing, a final detailed financial review is underway.

4. ISSUES AND OBSERVATIONS

4.1 THE BIDDING PROCESS

A two envelope bidding procedure was used. The technical and management proposals were submitted in separate envelopes from the financial proposals and evaluated as follows:

- On the date of submission, the proposal submissions were checked for content in the presence of the bidder at a public meeting.
- The technical and management proposals were opened at the same public meeting and verified by the committee. The financial proposals and

bids were not opened but securely stored until completion of the technical evaluation.

- The technical proposals were evaluated and judged as to their technical compliance by the technical working committee. The results of the evaluation were considered by the committee and the bidders notified of the findings.

- Financial proposals were opened at a second public opening and the bids posted. Financial proposals were subsequently evaluated for compliance.

This bidding process worked well. Firstly, evaluation of the technical proposal not only established the technical capability of the bidder, but it committed the bidder to meeting certain technical and operational requirements.

Secondly, the simple "pass/fail" evaluation of the technical proposals (as compared to assigning a "score" for a qualitative ranking of the proposals) simplified the process and removed much of the subjective judgement from the evaluation. The determination of the best bid was based entirely on who offered the best (highest) price.

Finally, the two step evaluation provided DOTC the opportunity to seek clarification of the technical offering of a bidder, prior to opening the financial proposals.

4.2 REGULATORY REQUIREMENTS

An important requirement was to make bidders assure DOTC of their responsibility for executing interconnect and revenue sharing agreements with adjacent operators ensuring full interconnection to the PSTN. In addition, DOTC solicited and received agreement from PLDT to continue existing interconnect and revenue sharing agreements with the winning bidder.

To include bidders who were not franchised, licensed or otherwise authorized to operate a telecommunications undertaking, the bid process allowed for an optional "operations and management" contract. This was to exist for an interim period until the selected bidder obtained regulatory approval and could enter into the preferred "financial lease" agreement.

The inclusion of non-franchised bidders through the use of an interim "operations and management" contract was for the purpose of enhancing competition among the bidders to bring out a final proposal that would be the most advantageous to the Government, the taxpayers and the telephone subscribers in question.

4.3 ACCOMMODATION OF EXISTING LOCAL OPERATORS

The intent of the bid process was to turn over all privatized facilities to a single operator. However, there was a requirement to accommodate smaller operators who had previously established themselves as the service provider in exchange areas where the government has installed, or plans to install facilities destined for privatization. A further consideration was the stated policy objective of having a single operator in any given local exchange area.

To ensure there would be only one operator per local exchange, the bid process provided a "right of first refusal" whereby existing operators will be given the opportunity to acquire privatized facilities in their exchange area. The bid documents have identified those exchanges where operators currently exist and has removed them from the bid process. The bidders have been instructed that the government will negotiate separately with the small operators for those facilities, but if the small operator cannot agree, the winning bidder will be obligated to take over those facilities.

Consideration of the private operators was a difficult but very important aspect of the bid process. Accommodating these operators greatly complicates the privatization of facilities as many separate contracts will be required. Also, the operators themselves will require agreements on interconnection, revenue sharing and joint operation of certain facilities. However, they must be accommodated as in many cases they are the establish service provider and are protected by their regulatory approval to continue.

4.4 LEASE STRUCTURE

As restrictions by the funding agency denied an outright sale of facilities, a "financial lease" was selected as the preferred form of agreement for transferring operation of the facilities to a private company.

The components of the lease, which the bidders were instructed to bid on include:

- An upfront payment
- An annual lease payment for the privatized facilities, stated per line of installed, operational capacity.
- A transfer payment at the end of the lease.

The bid proposals were evaluated on the net present value (NPV) of these three payments, with two additional constraints. Firstly, the upfront payment had to be no less than 25% of the first annual payment, and secondly, the present value of all payments had to exceed a "floor price" set by the government prior to accepting bids, but not made public until the bid opening.

A 30 year lease term was selected as this aligned with the repayment period of the loan, under which the facilities were procured. Other issues considered in structuring the lease were:

Incentives: Attempts were made to build in incentives for capital investment, system maintenance and personnel efficiency. All were abandoned for reasons of administrative difficulty or simply as being contrary to the philosophy that a qualified, private sector company can best operate a telephone system with a minimum of interference. The incentive which was given most serious consideration was the "capital investment fund". The concept was to have a portion of the lease payments deposited in an escrow account, to which the operator could apply for capital expansion projects. It was concluded the likely amounts available to the fund would not justify the administration requirements.

Revenue Based Lease Payments: Consideration was given to basing the annual lease payments on revenue, instead of capacity. This approach offered the advantage of allowing the government to share in the benefits of a successful operation (capture of so called "super profits"). It was also seen as a way to limit the risk of the operator should the system not perform to expectation thereby increasing the quality of the bids. However, revenue based payments were rejected as the accounting verification of revenues was seen as difficult and subject to misrepresentation. Moreover, high profits are limited by NTC limitations on the return on investment available to an operator.

Government Equity Participation: Mechanisms for government equity participation were considered, including joint venture arrangements, government stock options and government board participation. It was decided to not seek equity participation so as to minimize government involvement in the affairs of the operator.

4.5 OTHER ISSUES

Labor Issues: Alternative arrangements for the employees of Filphone (the company contracted to operate the RTDP phase A system) were considered in the bid process. One option was to obligate the winning bidder to employ personnel who were operating the system. However, agreement was sought and received from Filphone that they would continue to provide employment (with mutual agreement of the employee) for their employees.

Land Rights: Much of the land and right-of-ways acquired for the RTDP and NTP facilities has been donated or leased by local governments. It was decided to continue these agreements on behalf of the winning bidder, until such time as they can conclude their own agreements.

Ownership of Added Facilities: An important principal of the privatization exercise was that bidders would be asked to bid on a long term business opportunity not on a collection of equipment, buildings and facilities. In return for the right (in most areas, the exclusive right) to operate, the operator was obligated to provide public services, to expand and to modernize that is, to add facilities of their own. It

was clear that within 10 to 15 years, virtually all government facilities would be beyond their economic life. In the event of early termination of the lease, the issue of who owns which equipment could be a difficult one. It was agreed that ownership would be assessed on the depreciated value of the assets provided by each party to the system.

5.0 CONCLUSIONS

It has been just over one year since the Philippines undertook this first privatization project. For those considering a similar venture, here is a summary of the lessons we have learned:

- Establish Objectives. There are many reasons to privatize introducing organizational change, accessing new capital markets, accessing technology, etc. The objectives need to be clearly formulated, articulated and kept visible throughout the project.

- Organize. Privatization involves many government departments, agencies, companies and private sector organizations. Pulling together the right people, vested with the necessary authority is essential to overcome the inevitable politics.

- Maximize Competition. Open the bidding up to as many qualified companies as possible. Encourage outsiders.

- Consider Regulations. Moving to private operations will require an effective regulatory framework and an effective regulator. These need to be considered at the time of privatization as the strength and sophistication of regulation will often limit the structure of the privatized sector.

- Simplify the Bidding. Payment mechanisms, incentives, profit sharing and so on should be kept simple. Avoid downstream requirements for special accounting and monitoring systems.

- Consider the Issues. There are a number of side issues (such as labor, land use, etc.). These should all be considered upfront in the bidding process. This avoids contractual problem later in the process.

THE TELECOM GAP:
THE IMPACT OF COMMUNICATIONS TECHNOLOGIES ON DEVELOPING ECONOMIES

CARLOS HERNANDEZ-MEDINA AND JAMES HAMBLIN
CBIS DE MEXICO
CINCINNATI BELL INFORMATION SYSTEMS INC.
MONTERREY, MEXICO AND CINCINNATI, U.S.A.

A sophisticated communications infrastructure can drive economic, political, and social progress. Unfortunately, many developing countries lack such as infrastructure. Bridging the Telecom Gap requires identifying both the critical elements which make communications necessary to developing countries and the obstacles communications companies face when building operations in these countries.

Technology, in general, and communications technology, in particular, are changing the way we live and work. We're living in one of the most pivotal periods in world history. When historians look back at this time, they'll most likely contend that we were part of an almost-silent, certainly-bloodless revolution -- a revolution fought with ideas rather than guns, a world war against the elements that would deprive the world of its access to technology and information.

History will record this period as being the beginning of an era in which virtually everyone has access to technology. The era dawned with the introduction of radios, telephones, and televisions into people's homes and businesses. But it really began to grow ten years ago when IBM put the first personal computer on a desktop.

In 1981, that was a marvel. Today, it's frustrating. We want more memory, faster processors, higher resolution monitors. And we'll get what we want. PCs will probably be replaced by pocket computers that we'll carry around with us everywhere we go. With microchips thousands of time smaller than we have today, and with fold-up keyboards that are linked to home-based personal computers, these pocket PCs will surpass the power even of today's mainframes.

They'll monitor our blood pressure and pulse rate. They'll determine peak periods for physical activity and creative tasks. They'll handle our administrative chores while we spend time thinking. Frankly, we can't even imagine some of the things they'll end up doing for us.

Similarly, the car phone will probably be supplanted by the wristwatch phone. It will follow us anywhere in the world, incorporating features such as voice mail and extensive memory for phone numbers and other rolodex information. It'll find us wherever we are -- in Cincinnati or Cancun or Lagos, Nigeria.

In one way, the world will become a smaller place. Because there will be practically no place we can go without staying in touch. On the other hand, the world will be a larger place, because we'll be able to go practically anywhere and still stay in touch.

The historical significance of this period, then, is likely to be that the limiting concept that divided the globe into first, second, and third worlds will be obsolete. There will be only one world -- one first world -- in which we are all linked by a global highway of information. It's already happening. We're living in an era in which instantaneous communications have created a global financial market. Our economies and technologies are so inter-connected that we're transacting more than $1 trillion worth of business on-line, every day.

Companies no longer need to concentrate their offices or plants in the U.S. or even in major cities because they now have massive private communications networks that span the globe. Ford Motor Company, for example, operates 23 high-speed voice and data lines that support 100,000 computer terminals and 95,000 employees. This network enables managers in Ford's Hermosillo plant, where the company builds Escorts, to talk with designers in London, lawyers in Washington, or executives in Detroit.

In fact, corporate voice, data, and teleconferencing traffic among different countries is soaring by 15% - 20% a year, about double the corporate rate in the continental U.S. In October 1991, the *Wall Street Journal* predicted that international traffic will grow by at least 12% a year to more than $14 billion annually by the end of the decade. These examples illustrate the extent to which telecommunications has reshaped the business world, particularly in developing countries.

American Airlines now earns more revenue from its computerized reservation center than from its traditional airlines business. And that reservation center is not in New York or London or Paris. It's in the Dominican Republic.

Data entry companies -- owned, operated, and staffed by nationals -- are experiencing extraordinary growth in places that a few years ago would have seemed unlikely, such as Jamaica, Barbados, Thailand, and Malaysia.

As recently as five years ago, a company like CBIS could not have justified a multi-million dollar investment in a new data center in Mexico. Today, that justification is easy to make; the market demand for data services in Mexico -- and throughout much of Latin America -- is skyrocketing. We see our investment in Monterrey as a major opportunity to get in on the ground floor of a rapidly-growing marketplace.

In one country after another, we're seeing the payback that comes from investments in the communications infrastructure. Benefit/cost ratios in countries such as the Philippines and Costa Rica have been established at 5/1 and, in some sectors, even 48/1. The Bell Operating Companies commissioned a similar study of telecom's economic impact in the U.S. They found that, even in the U.S., with its sophisticated network, telecom advancements had saved the economy more than $80 billion during a 20-year period.

But even with the support of such overwhelming evidence, developing countries still face major questions each time they consider modernizing their telecom sectors. For example, it's obvious that the global network has become the arterial system that links our worldwide economy together. But can that network -- particularly in developing countries -- keep up with user demands and traffic volume that are increasing exponentially year after year?

As the global network becomes so critical -- and so sophisticated -- developing countries have to make major telecom investments if they're to achieve their economic development goals. But can these countries justify such investments when they have so many other pressing needs, including housing, health care, and education?

Some people advocate deregulation and privatization as a way to address these issues. Clearly, privatizing state-owned companies and encouraging competition often generates the capital and momentum necessary to build a modern communications industry. But can developing countries embrace these options and still ensure that areas outside the urban business centers have access to telephone service?

The answer to all these questions can be a resounding 'yes.' But only if all of us -- the wireline carriers, the non-wireline carriers, and the vendors who support your industries -- recognize the important roles we each play in building the communications infrastructure.

WIRING THE WORLD—AGAIN!

Consider how the "wired world" has driven economic growth and how the "wireless world" is now helping to sustain that growth.

A key component of economic growth throughout the world has always been a country's transportation infrastructure. The industrial revolution is a good example. Its mushroom-like growth was sustained because the industrializing countries embarked upon massive public works projects, building roads and bridges and canals. The British navy was the catalyst that enabled Britain to grow into the largest empire in history. U.S. railroads in the mid-19th century and its interstate highway system in the mid-20th century contributed greatly to the United States' phenomenal growth.

Again and again, transportation has been the critical link that enabled commerce to flourish. And it's still important; from the shipping industry to the growing courier industry, the need to move materials and products and packages is as great as ever.

But in addition to traditional means of transport, there is also the need to move an incredible volume of information -- not just from region to region but from continent to continent. And not just from day to day but from second to second.

Information has become the most critical business commodity in the world. We're at a point in history not unlike that faced by business half a century ago when the world was being wired for the first time -- not for information but for electricity. During that period, in the 1930s and '40s, industries like aircraft production, food processing, and chemical manufacturing -- industries that utilized sophisticated electrical machinery -- succeeded while old-technology industries like agriculture and mining lost profitability and prominence. The same dynamic is at play today. Industries that utilize information as a strategic asset are thriving. Industries that do not are at a serious competitive disadvantage.

The point here is that developing economies face the same challenge today that their counterparts faced 50 years ago: get wired or get out. The regions of the world that "electrified" their urban and rural areas -- like the U.S. and western Europe -- were prepared to compete in the modern economy. Those that didn't fell behind. And the gap separating the developed and developing worlds widened farther than at any other time in history.

Today, the gap separating the so-called "developed" and "developing" countries is defined by access to information. It's the "Telecom Gap." There are roughly 600 million telephones in the world and three-fourths of

them are concentrated in just nine advanced countries. The remainder are scattered unevenly throughout the rest of the world. Tokyo, for example, has more phones than the entire African continent.

The "Telecom Gap" is significant because telecommunications is no longer a luxury. It has become a critical engine of economic growth. Without access to information, developing countries lack the ability to attract foreign investment. Their own industries are ill-equipped to compete in the world economy. And their people are denied what has become a staple in the developed world.

But just because telecommunications isn't a luxury doesn't mean it's suddenly affordable. Or that countries can easily manage the transition from public to private telecommunications industries.

NO LONGER A NATURAL MONOPOLY

The International Telecommunications Union, or ITU, has estimated that most developing countries could probably increase the number of subscribers connected to their networks by 4% to 6% a year. Obviously, the demand for new service dramatically exceeds this rate. And even this meager improvement is accomplished only by reinvesting all of a telco's profits back into the network -- meaning these funds can't be used by the government for other critical needs, such as housing, medicine, and education.

In addition, with only a few exceptions -- Brazil, China, and India, for example -- developing countries don't have indigenous communications manufacturing industries. As a result, in many countries, 60% or more of the cost of a major telecom project has to be paid for in hard currency. And, as we all know, hard currency often has to be diverted to other national obligations.

The financial disparity here is made even more evident when you realize that the developed world invests more than $100 billion a year building and enhancing the global telecom network. For example, AT&T and several partners are spending more than $3 billion just to lay a transoceanic fiber line capable of transmitting five billion bits of information a second.

In most cases, brutal financial realities simply prohibit developing countries from keeping up with these investments. And the result is that the "telecom gap" separating regions of the world threatens to segregate entire nations, economies, and people.

Something has to be done. The developed countries reap no benefits from keeping developing nations out of the telecom club. In fact, it is much more advantageous for the developed world to eliminate the gap. A healthy communications industry and infrastructure in the developing world creates new labor supply. These new jobs strengthen developing economies. And as these economies strengthen, new markets emerge. It is a self-perpetuating cycle of progress.

It's because of this cycle that privatization and deregulation make so much sense. Many countries are concluding, as we in the U.S. did a few years ago, that telecommunications is no longer a natural monopoly. A much broader array of services can be offered at significantly lower rates in a dynamic, competitive environment than in a monopolized environment. Traditional monopolies lack the resources, the expertise, and the desire to keep up with a market characterized by private networks, teleconferencing, faxes, and the like.

Still, telecommunications ministries have to balance the need to enhance their networks with the need to provide universal service to rural as well as urban regions. An unregulated, highly-competitive market will almost always direct resources to urban business centers rather than to "thin routes" in less-populated areas. We've observed this phenomenon in the U.S., where cellular service grew rapidly in metropolitan areas but has been much slower to arrive in rural parts of the country.

Ideally, of course, universal service would be provided evenly throughout a given country. But that ideal is not realistic. For most countries with very limited capital, only one priority at a time can be afforded: either you concentrate on providing plain old telephone service to ever-wider segments of the population or you invest in enhancements to the network to support commercial usage.

Plain old phone service is important but it doesn't pay off like high-tech business service. You can't expect a company like Ford, for example, to build sophisticated plants in regions that can't support its communications needs.

A country like Mexico, however, that offered the necessary communications support, was able to entice Ford to build a stamping and assembly plant in Hermosillo and an engine plant in Chihuahua. Today, Ford is using a mix of telecommunications services made possible only by deregulation: TelMex is providing wireline service, Norcel and Movitel are providing cellular service, and TELECOMM is providing access to the Morelos satellites. This is a perfect example of how a deregulated communications industry can directly affect economic growth.

MAXIMIZING MARKET STRENGTHS

Deregulation alone, however, is not enough. The competitive mix made possible by deregulation has to include a country's established carrier. Unfortunately, most state-owned carriers are burdened by inefficiency, bureaucratic roadblocks, and inadequate capital. In a competitive environment, they are at a serious disadvantage, with the apparatus of the state hanging like an albatross around their necks.

But, when properly managed, these national carriers can have an important edge over their competition. First, start-up companies -- alternate access carriers, value-added resellers, and so forth -- lack the market presence of an established carrier. They have to build their infrastructure and operations from scratch and spend the critical first years of their existence playing catch-up.

Second, even major international players, such as AT&T, Cable & Wireless, and NTT, lack the market knowledge of an indigenous carrier. They may have the capital and the technological expertise to enter the market aggressively, but they face a steep learning curve because they cannot be as familiar with a country's telecom marketplace as that country's own carrier.

The question, then, is how to encourage competition, on one hand, and enable the national carrier to leverage its strengths, on the other. Privatization is an attractive option. It maximizes the strengths of established in-country carriers, alternate access carriers, and foreign investors while encouraging synergies among them. A privatized company like TelMex leverages the carrier's market presence and knowledge with the capital, technology, and management expertise of its competitors.

In addition, privatization can also provide a country with much-needed infusions of cash. Jamaica, for example, sold 20% of its carrier to Cable & Wireless for $55 million. Argentina sold a portion of EnTel to France Telecom for $1.5 billion and, of course, 20% of TelMex was sold to a private consortium for nearly $1.8 billion.

Of course, there are those who oppose the surrender to foreign interests of national sovereignty over telecommunications. But many believe that concern is largely unwarranted.

Look at TelMex, as an example. Today, Mexico has about five lines for every 100 people, compared with the worldwide average of ten lines for every 100 people. And more than 70 percent of Mexico's lines are for residential use, which really isn't contributing as greatly to economic growth.

Since Grupo Carso acquired its controlling interest in TelMex, it has introduced a new network of high-tech services to meet the needs of Mexico's business community. With a new fiber optic network that stretches for nearly 14,000 kilometers, TelMex will be able to increase cross-border communications capacity five-fold, an achievement that will help attract more companies like Ford. Approximately 400 Mexican businesses have already signed up for these new services and demand continues to escalate. One TelMex official compared it to selling water in the desert.

Privatization is a necessary complement to deregulation. Together, these options become a powerful catalyst for growth. Mexico has demonstrated that, when managed properly, a privately-run national carrier, competing with a diverse field of other communications providers, can be the key to developing a modern telecom industry -- and, consequently, a healthy, growing national economy.

THE EVOLVING ROLE OF CELLULAR

The greatest benefit of privatization and deregulation is that it enables sectors of the industry -- such as cellular -- to become an increasingly important part of the picture.

A truly world-class communications industry is characterized by strong players whose growth comes as a complement to -- rather than at the expense of -- the other sectors of the industry. Cellular is certainly a good example of this.

Cellular service providers have two distinct roles. The first is to provide a reliable alternative to the often-unreliable wireline network. Businesses can't afford to wait months and even years to establish phone service. They can't compete when their call completion rates are 50 and 60 percent. They need high-quality voice and data transmission capabilities. And they need it today.

The cellular industry can provide a critical service by meeting these demands. Throughout Mexico, companies like Cedetel and Portatel are providing their customers with the vital communications links they need today. But, it's important to remember that this role does not have to be -- and probably shouldn't be -- the long-term vision of your industry.

The wireline network here is improving. The owners of TelMex have pledged to upgrade the network and expand service significantly over the next few years. If all goes well, Mexico could have a world-class wireline network by the end of the decade.

If it is to have a world-class communications infrastructure, however, it needs more than just reliable wireline telephony. It needs the broad mix of services that are made possible by a deregulated environment. And for that to happen, alternative carriers -- both wireline and non-wireline -- need to see themselves as value-added complements to the network.

The cycle of progress discussed earlier applies in this instance, as well. A strong wireline infrastructure will support the growth of an equally-strong non-wireline infrastructure. Both sectors become pillars that support and lift the industry as a whole.

The world's leading cellular markets are strong evidence. In the U.S., for example, cellular has never played the role of alternative technology. From day one, the U.S. cellular industry has marketed itself as a complement to wireline telephony. And more than 5 million people in the U.S. are cellular subscribers. That's two percent of the population. In Mexico, two percent equals 1.6 million. That's 1.2 million more than some people believe is the maximum market here.

Unbelievable. If Mexico's communications industry as a whole is encouraged to grow, you can realize cellular growth rates that are probably beyond your wildest projections right now. Grow your industry and your markets will follow.

You'll benefit. Your customers will benefit. And, as the bridge across the Telecom Gap is built, the rest of the world will benefit.

ELECTRONIC BYWAYS: CREATING TELECOMMUNICATIONS INCENTIVES FOR ECONOMIC DEVELOPMENT

Heather E. Hudson, Ph.D., J.D.
Director
Telecommunications Management and Policy Program
McLaren School of Business
University of San Francisco

ABSTRACT

This paper examines various approaches to creating incentives for investing in and utilizing telecommunications for economic development. These approaches include incentive regulation, changes in rate structures, introduction of competition in services, and interdisciplinary task forces to set goals and priorities. Lessons from the U.S. experience are highlighted that could be applied in other countries seeking to to enhance the role that telecommunications can play in their economic development.[1]

1. Introduction

Deregulation of telecommunications in the United States has been embraced at the federal level, but is also being widely adopted at the state level. Approximately half of the states now have some form of incentive regulation, as opposed to the traditional form of rate-of-return regulation.

Many of these plans are adopted in the name of economic development, with the rationale that states need state-of-the-art infrastructure to be competitive. Yet more than investment in facilities may be needed to ensure that telecommunications contributes to economic development. For example, investment in other infrastructure and affordable pricing of telecommunications capacity for education and social services may also be important. In addition, telecommunications investment is likely to pay off when combined with other factors such as a good transportation system, an educated and reliable workforce, and high quality education and community services.

1. More information on state plans and policies addressed in this paper can be found in Parker, Edwin B. and Heather E. Hudson, Electronic Byways: State Telecommunications Policies for Rural Development, Boulder, CO: Westview, 1992.

2. Regulatory Policies

State regulators may introduce new policies designed to replace rate-of-return regulation with flexibility in rate setting in return for commitments from carriers to upgrade rural facilities and/or imp ve rural services. Special deregulatory policies ma also be introduced for small telephone companies.

Incentive-Based Deregulation

Several states have introduced changes in regulation that allow the carriers considerable pricing flexibility in return for meeting certain conditions. Some states have adopted price caps, which replace rate-of-return regulation with caps on pricing tied to the rate of inflation. Typically, the carrier has considerable pricing flexibility within a range, and must share profits above a certain threshold with its customers. New York was the first state to introduce incentive regulation, in 1986. The California Public Utilities Commission (CPUC) has approved an incentive regulation structure for Pacific Bell and GTE California that will peg prices of the carriers' monopoly services to a productivity-based inflation index. Nebraska is acknowledged as the state that has gone the farthest in deregulating intrastate telecommunications.

Some states have tied deregulation of the carriers to incentives to upgrade infrastructure:

Michigan: The Public Service Commission (PSC) has implemented an incentive regulation plan requiring the BOC to invest a portion of any earnings above 13.5 percent return on equity in network improvement projects not covered by the company's normal $520 million annual construction budget. The balance of the excess profit is split between the company and ratepayers. Michigan Bell has forwarded to the commission a list of enhancements totaling $55 million. It is proposing to spend $29 million to install digital switches on Michigan's rural upper peninsula, $12 million on fiber optic deployment, and the remaining $14 million to upgrade residents from multi line to single line service.

Tennessee: The Tennessee Public Services Commission (PSC) has adopted a master plan that ties regulatory reform to technology deployment. The plan provides earnings sharing and pricing flexibility for local telephone companies provided the companies commit to meeting the 10-year plan which includes deployment of SS7 and eventually ISDN, fiber trunks and switched broadband services.

Texas: As part of a settlement in a rate case before the Texas PUC, Southwestern Bell will replace all of its electromechanical switches in Texas with digital switches over a four year period.

"Social contract"

In this model, regulators, telephone companies, and representatives of users including businesses, social services, and residents agree on policies designed to upgrade services, maintain affordable access, and provide flexibility to the telecommunications carriers.

Vermont: In December 1988, the Vermont Public Service Board approved a five-year agreement with New England Telephone that substantially altered the regulatory framework in Vermont. The Vermont Telecommunications Agreement (VTA) is not total deregulation nor a rate case settlement, but an attempt to modify the regulatory approach to respond to both cost and competitive pressures. A social contract model was adopted, requiring the building of consensus among the state government agencies, consumer representatives, the carrier, and other interested parties. The goal of the social contract was to stabilize rates for basic exchange service and set minimum service quality and modernization criteria for consumers, in exchange for relief from rate of return regulation and greater marketing flexibility for the local exchange carrier.

Deregulatory Policies affecting Small Telephone Companies:

Some states have adopted deregulatory policies not only for major carriers but also affecting small telephone companies. For example, Indiana has deregulated telephone cooperatives. Idaho is considering deregulating small stock telephone companies.

3. Rate Structures Designed to Reduce Rural Disparities

Several approaches have been adopted to reduce the disparities in cost for access to telecommunications and use of telecommunications services in rural areas.

Subsidies for Installation:

Link-Up America: This a federal program designed to preserve and promote telephone subscribership among low income households. Funds are provided to offset 50 percent of the tariff charges for connecting a subscriber to the telephone network. This program is available in urban as well as rural areas, but may be particularly important to rural residents who must travel long distances to get help or exchange information if they lack a telephone.

Several states have programs to subsidize installation in high cost rural areas. For example, in Wyoming, first time telephone service is provided for an installation fee of $375 if costs are under $10,000; the customer pays half the costs in excess of $10,000.

Subsidies for Low Income Subscribers:

Lifeline Service: The FCC has authorized a lifeline service fund, to be matched by state regulators, to help make telephone service affordable to low income subscribers. Most states offer special monthly rates for basic telephone service to customers who meet established low income criteria. Some states such as Arizona, Idaho, and New Mexico are making particular efforts to publicize these programs in rural areas in order to increase participation by the rural poor.

Extended Area Service (EAS):

In many rural regions, callers must pay long distance charges to reach businesses and government agencies that would be accessible with a local call in the city. Several states have implemented policies that enable rural residents to call an extended area for a flat rate, as a means of reducing disparities between rural and urban subscribers.

Colorado: The commission is implementing a plan to create the largest calling areas in the U.S. Costs will be shared by all Colorado residents through slight increases in monthly rates.

Georgia: The state has mandated a county seat calling plan whereby all residents can make free calls to government agencies in the county; it is now introducing county-wide EAS.

Louisiana: The commission has implemented a Local Optional Service (LOS) Plan that caps rates on toll calls within 22 miles of a county/parish calling area. The plan came about through rate case proceedings in which the commission ordered a rate reduction of $36 million, half to be achieved through a reduction in access charges and half through the LOS plan.

Washington: The Washington Utilities and Transportation Commission (WUTC) adopted rules to identify and expand local calling areas where customers must rely excessively on toll service to meet basic calling needs. Telephone companies must identify exchanges in which the average customer can complete less than 80 percent of intraLATA calls toll free. For exchanges that fall below the 80 percent threshold, telephone companies must evaluate possible EAS routes, and propose EAS additions and rates to the Commission. Increased costs that result from expanding local calling areas will be recovered first from customers who directly benefit from increased calling areas. If additional funds are needed, the last source will be increased local rates.

West Virginia: Local calling areas are being established within a 22 mile radius of home exchanges.

4. Economic Incentives: Aggregating Demand

Rural areas often lack economies of scale that would make provision of new services attractive, such as equal access to alternate long distance carriers. With the approval of regulators, small companies may aggregate their demand through pooling traffic to provide a viable market for new services.

Iowa Network Services (INS): INS is a consortium of small independent telephone companies established to concentrate traffic in order to enhance offerings of equal access. Through INS' Des Moines access tandem, long distance carriers have a single point of access for some 150,000 subscriber lines of the INS' member telephone companies. This centralized switch provides inter and intra LATA equal access to 128 rural telephone companies. Iowa is the first state to implement 1+ presubscription and balloting for intra-LATA long distance services.

Kansas: Kansas Independent Network, Inc. (KINI) was formed by 29 independent telephone companies and cooperatives. Kini was established to enhance the independent telephone companies' ability to win cellular lotteries, and is building rural cellular systems in nine areas. It is considering carrying long distance traffic and offering equal access to distance carriers to its customers.

Minnesota: Ninety independent telephone companies have joined together to create Minnesota Equal Access Network Services (MEANS). Using digital technology and optical fiber, MEANS intends to offer centralized equal access and other competitive services currently unavailable in rural Minnesota.

South Dakota: South Dakota Network (SDN) has selected Sioux Falls as a central point from which to offer IXCs cheaper rates to reach rural exchanges than the cost of doing it themselves.

5. Pricing of Services

From the users' point of view, access to technology involves not only availability of equipment but ability to afford to use it. From the carriers' point of view, providing access to educators is not cost free. They must determine how much to charge for use of their facilities. If they decide to offer the services at reduced prices or for free, they must justify this decision, keeping in mind regulations in their state as well as their shareholders. For example, to provide access to unutilized capacity such as "dark fiber," the problem for the phone company is to allocate costs to reflect the fact that these users are benefiting from otherwise unutilized capacity.

Several approaches may be used for pricing these services:

Existing tariffs: Carriers may use existing tariffs, which typically include reduced rates for high volume or off-peak use, and may provide discounts for government users.

Free access: Carriers may decide to provide access to their facilities without charge. Often, this approach is used for a trial or pilot project of fixed duration. At the end of the period, the user must pay to continue to use the capacity.

Reduced prices: To demonstrate their commitment to the community or region, and/or to showcase their technology, carriers may agree to offer educators access to their facilities at reduced rates. Two models appear to be used at present:

- **waiver:** The state's regulatory commission approves a waiver of the existing tariff for educational applications, based on the benefits to the community or state that would otherwise not be obtained. The waiver is generally approved on a case-by-case basis, and may apply only to some carriers or for a limited period.

- **special tariff:** A special tariff may be approved for educational applications. For example, in Maine, the carriers provide access to educators at cost, in an agreement negotiated between the state and the telephone company (Silkman, 1991). In Kansas, the Kansas Corporation Commission (KCC) created a special class of "Economic Development Rates" based on incremental rather than fully allocated cost accounting. These rates are determined on a case-by-case basis, and are designed to recognize the unique circumstances and economic development potential of a particular project or service (Davidson et al., 1990). This rate has been applied to an educational interactive video project in

Kansas involving three telephone companies.

5. Task Forces and Studies as Catalysts for Change

As the role of telecommunications in economic development has become a more visible issue, several states have established task forces to help reach a statewide consensus to revamp state telecommunications policy. The task forces usually bring together a range of participants who share an interest in either telecommunications or development -- telecommunications policy makers, government users, educators, business and other users, and the telecommunications industry.

Alabama: The Information Age Task Force was set up to explore current and future benefits of the intelligent network, issues raised by its deployment, and impacts on all Alabamians, urban and rural. The Task Force is composed of 17 individuals representing small business, the elderly, the disabled, agriculture, education, health care, social services, small municipalities and state government.

California: The Intelligent Network Task Force, sponsored by Pacific Bell, brought together individuals representing California's diverse ethnic and public service constituencies. The group prepared a report explaining how new telecommunications technologies and services could benefit Californians, and recommending widespread access to new services (Intelligent Network Task Force, 1987).

Michigan: A Governor's Telecommunications Task Force including representatives of the Public Service Commission and state departments of commerce, education, labor and management and budget produced a report outlining a strategy for Michigan's future through telecommunications. The task force's chief recommendation was to develop an integrated statewide high capacity switched network (Governor's Telecommunications Task Force, 1990). The task force also commissioned a "Use Assessment of Michigan's Telecommunications Systems" (EDS, 1990).

Minnesota: A study by the Citizen's League looked into ways Minnesota can use new technologies to create opportunities for business and the public. The goals of the Citizen's League are to use Information Age technologies to provide improved public education and health, better government services, economic growth, political awareness, efficiency and productivity and reduce the need for transportation (Citizens League, 1989).

New Jersey: The New Jersey Board of Public Utilities (NJBPU) initiated a study of telecommunications infrastructure funded by the state's three local exchange carriers. The study examined the economic impact of rewiring the state with optical fiber. The report concluded that an advanced telecommunications infrastructure is essential for New Jersey to create the number of new jobs desired for the state (Deloitte and Touche, 1991).

North Carolina: The state has established a task force with forty representatives from the governor's office, education, business, and the telecommunications industry to determine how the state could use telecommunications to attract new businesses, enhance productivity, and upgrade education levels.

Oregon: A task force appointed by the governor included representatives from schools and higher education, local government, large and small users, a telecommunications consultant, and the Oregon PUC. The task force report urged state leaders to develop integrated telecommunications and information technology policies (Task Force on Telecommunications, 1991).

Tennessee: The Information Systems Council is composed of several heads of state government agencies (finance and administration, general services, treasury), a commissioner of the Public Services Commission, 6 legislators and 2 private sector representatives. This council is examining options for investing telecommunications and information technologies to help to diversify the state's economy.

Washington: A Telecommunications Task Force with members drawn from GTE Northwest, US West, and Global Telematics examined future telecommunications services and potential benefits for the state of Washington, with input from consumers, academics, and government.

6. Lessons from the U.S. Experience

While the specifics of the structure and regulation of the telecommunications industry in the U.S. differ from conditions in other countries, there are several lessons from the U.S. experience that could be relevant to other countries concerned with upgrading infrastructure or extending services in support of economic development.

User Participation

User participation is critical if appropriate new technologies and services are to be introduced and rates are to be kept affordable. The involvement of users with regulators and telecommunications industry representatives has been an important component of the planning process in many states. It is still too early to assess the impact of the task forces described above. Yet the process seems valuable, particularly when it involves broad-based participation from government, carriers, and users, both business and residential. To be effective in bringing about change, they should formulate clear goals and plans for reaching the goals. Also, they should have high level support in state government.

User involvement in the regulatory and legislative process has also been important in changing rate structures such as EAS and introducing special rates or discounts for educational uses.

Integrated Planning

Among the recommendations of the task forces were several that could help governments better integrate telecommunications planning with development goals:

- Coordinate government policy making in telecommunications: Michigan proposed establishing a Cabinet Council on Information Technology to coordinate state government efforts in telecommunications and information technologies;

- Facilitate input from users in the policy process. Michigan proposed setting up a State Telecommunications Users Group to provide a means to focus user input to telecommunications management, simplify user needs analysis, assist in standards selection and analysis, and promote shared services and applications;

- Measure progress: Oregon recommended adopting a set of performance measures for the state government's networks and the public telecommunications infrastructure;

- Coordinate planning for voice and data: Oregon proposed eliminating distinctions between telephone (voice) and information technology (data communications) in planning and management of state government networks;

- Try out new services and applications that support state development goals. Hawaii carried out a pilot project on telework to test the viability of reducing travel time and congestion by enabling people to work nearer home using telecommunications; and

- Upgrade telecommunications infrastructure: Reports from several states, including California, Michigan, and New Jersey recommended accelerated deployment of a reasonably priced high capacity network that would benefit business, education, and health care delivery.

The Importance of Incentives

Both regulators and the industry realize that there are many flaws in the "stick" approach of rate-of-return regulation. It is still too early to judge the effectiveness of the "carrot" approaches of incentive deregulation and increased competition. However, other countries may also want to consider strategies that create incentives for investment in appropriate infrastructure.

There are also several models that can be used to introduce incentives through competition. Developing countries are generally reluctant to introduce public network competition because they believe that there are significant economies of scale, and therefore duplication would be wasteful. However, most agree that competition can be successfully introduced in customer premises equipment (CPE) and value added networks or services (VANs).

Yet lack of capacity is a serious problem in many developing countries, and cannot be solved simply by selling telephones and other equipment on the open market. Several strategies may be used to provide capacity where direct competition is considered unacceptable:

- **Resale:** Third parties may be permitted to lease capacity in bulk and resell it in units of bandwidth and/or time appropriate for business customers and other major users. This approach may be suitable where some excess network capacity exists (e.g. between major cities or on domestic or regional satellites).

- **New Services: Franchise or Competition:** The introduction of a new service may be accelerated by issuing licenses for franchises. This approach has been used for cellular radio in several countries.Satellite services such as data communications may also be offered through one or more private licensed carriers. Yet there are dangers of distortion if policy makers do not carefully frame incentives. In Malaysia the price of installing a cellular radio is 1.5 times the national per capita GNP, thus excluding rural communities which were also supposed to benefit from the service (Wellenius et al., 1989). Policies may be framed to generate funds for other priorities. For example, carriers may charge license fees and/or operate base stations or uplinks for the private networks. They might also require that a percentage of the revenues of these services be allocated to implement other services, such as low cost fixed cellular outlets and thin route telephony via satellite.

Local companies: Although in most countries there is a single carrier that provides both local and long distance services, it may make sense to delineate territories that can be served by local entities. In the U.S., the model of rural cooperatives fostered through the Rural Electrification Administration (REA) has been used to bring telephone service to areas ignored by the large carriers. Local enterprises are likely to be more responsive to local needs, whether they be urban or rural. Cooperatives have been introduced in Hungary. Another example of this approach in urban areas is India's Metropolitan Telephone Corporation established to serve Bombay and Delhi.

- **Franchises for Unserved Areas:** Another approach to serving presently unserved areas is to open them up to private franchises. Large carriers may determine that

922

some rural areas are too unprofitable to serve in the near term. However, this conclusion may be based on assumptions about the cost of technologies and implementation that could be inappropriate. A more innovative carrier willing to use more appropriate technology such as rural radio systems or small earth stations and to cut costs by hiring local people rather than bringing in outside staff, may be able to run the system at a profit. In Alaska small telephone companies operate local service in villages where earth stations were installed by Alascom, the statewide long distance carrier. Some U.S. states are considering competitive franchising of territory that the large carriers claim is prohibitively expensive to serve (Parker and Hudson, 1992).

The Fallacy of Deregulation

The changing telecommunications environment is often referred to as "deregulation." In fact, virtually everywhere but the U.S. and Canada, the result of changing the telecommunications structure has been the need to introduce regulation where none existed.

When an autonomous structure is established, there becomes a need for oversight. This is particularly true in a monopoly environment, to ensure that the single provider does not abuse monopoly power in setting rates or discriminating between customers. As Goldschmidt points out, liberalization of itself cannot assure competition absent structural and behavioral restraints on former, or "transitional" monopolists (Goldschmidt, 1991). However, even a competitive environment is likely to require some oversight to ensure that service providers are competing fairly, and that their collective activity is serving the national interest.

The functions that a regulator will need to perform or at least supervise include:

Pricing: Where competition exists, the marketplace may serve as a means of ensuring that prices are reasonable. However, for monopoly services, or where demand far exceeds capacity, regulatory intervention may be necessary.

Explicit Subsidies: Internal cross-subsidies are often used to provide affordable services in less profitable areas. With the introduction of competition, it is important to make such subsidies explicit where they remain necessary, in order that a dominant carrier cannot use them to engage in predatory pricing.

Quality of Service: With deregulation comes the potential for degradation of service in less profitable areas, as carriers strive to expand and upgrade the most profitable services. Concern about the deterioration of rural services has been expressed at the state level in the U.S. as well as by consumers in Canada, the U.K. and Australia. It may also be possible to tie service quality standards to other incentives such as pricing flexibility.

Criteria for Access by Multiple Providers: Where service competition is allowed, oversight will be required to ensure that all have equal access to the network, and that the provider of facilities does not enjoy an unfair advantage if it also offers services.

Standards: Uniform standards are required to ensure that equipment is compatible and of acceptable quality. An impartial standards agency will ensure that a dominant carrier or supplier does not introduce standards that unreasonably discriminate against other vendors.

8. Conclusion

The goal of using telecommunications to contribute to development requires an active government policy to ensure that telecommunications plans and services are designed to meet national goals. It also requires flexibility and innovation in services, equipment and pricing to respond to user needs. The states in the U.S. are now undertaking a variety of innovative approaches to regulation, pricing, and planning telecommunications services. This may be considered an experimental phase, since these changes are still too recent for definitive assessment. However, many of the strategies appear promising as means to foster investment in telecommunications and utilization of telecommunications services that will support socio-economic development. The most important challenge for the U.S. and for other countries will be to plan and manage telecommunications not only as a source of revenue but as a strategic resource for development.

Bangkok, Thailand

1. ABSTRACT

Some advanced telecommunication services, which can improve business efficiency and lead to the creation of new jobs, are reviewed. Industry sectors sectors which will benefit from those services are examined. This is followed by a look at the status of implementation of new services across many Asia/Pacific countries today and the impact on jobs. Finally, we discuss an option for actual implementation which can both provide advanced services and speed implementation of the basic telecommunications network.

2. INTRODUCTION

New telecommunication services and technology are changing the world economy as business becomes increasingly information intensive. The extent to which telecommunications today can impact the distribution of jobs and work is not widely appreciated. This is particularly important to the developing countries of the Asia/Pacific region.

Asia/Pacific countries generally place a strong emphasis on technology transfer to their countries. A major reason for this has been creation of manufacturing jobs. But this is not the only alternative for job creation. In fact, it is critical to developing countries to take advantage of the many new job opportunities in the information sector. The potential for job creation in the information sector and many other sectors is larger than than in the manufacturing sector. And most of these jobs do not require the capital investment that is generally required for manufacturing facilities.

The creation of jobs in many industry sectors in developing countries can be greatly accelerated through the use of telecommunications. Advanced business telecommunications capabilities, which will allow jobs to be created in the services sector, are critical to the economies of all countries.

Advanced telecommunications is already creating jobs in both developed and developing countries today. For example, one company, based in the USA, is making extensive use of software developed for that company in India. Sophisticated satellite communications transport the daily production of software engineers between India and the USA.

Businesses in the developed world can take advantage of generally lower labor rates in the developing world. Developing countries can provide more challenging jobs within their boundaries, as advanced telecommunications erases the problem of distance for people working together in widely dispersed geographical locations.

3. ADVANCED TELECOMMUNICATION SERVICES

3.1 Some Advanced Telecommunication Services Which Create Jobs

In this section we will look at some advanced telecommunication services which go beyond simple transport of information.

Global Automatic Call Distribution

A common requirement in many industries is to make up-to-date customer records available to an agent handling a phone call. For example, a customer may call an insurance company to make a change in coverage.

Typically, such calls are routed to an Automatic Call Distribution (ACD) center. ACD centers are used because they improve efficiencies in handling incoming calls. The most recent advances in ACD allow use of Calling Line Identification to identify the probable customer, from a data base of customer telephone numbers. The records for that customer are then automatically retrieved from a data base of customer records, and delivered to the answering agent's data terminal at the same time that the voice call is routed to that agent.

The process of obtaining the customer's records, based on calling line identification, and delivering them automatically to the agent handling the call saves valuable time, making the agent more efficient. It also makes the agent more responsive to the customer, because the agent does not have to engage in a long dialogue to determine the customer's identity, and then locate the customer's records.

Automatic Call Distribution (ACD) centers could be globally distributed. Some multinational companies, such as airlines, are considering offering twenty four hour service, making use of reservation centers on different continents. For

example, when the end of the business day is reached on one continent, calls could be routed automatically to a reservation center on another continent.

Such an approach will make it possible for companies to put some of their jobs in developing countries, where agents could handle incoming calls for a large variety of applications. To verify the economics, we did an analysis of the breakeven point for placing an ACD center in a developing country in Asia, and routing calls to the center from the USA. The tradeoff was done assuming a DS-1 circuit could be leased, over which all calls would be routed.

At current trans-Pacific DS-1 tariffs, and at current salary levels, an ACD center serving customers in the USA with approximately 40 agents would cost the same to operate in a developing country in Asia as it would in the USA. This is considerably smaller than the size of a many ACD Centers in operation in the USA today. A larger center in Asia would cost even less to operate.

As many more circuits come into operation in trans-Pacific routes through the new fiber optic cables being laid, tariffs will go down. As a result, the cost of operating an Asian ACD Center in a trans Pacific application will become even less. This will make it even more attractive for companies in the USA, Japan and Australia to place ACD centers in developing countries in Asia. The only thing a developing country need do is to provide the capability for private ACD centers to be connected to their public network or to provide this capability as a business service in their public network. Public network based ACD centers are a reality today in North America.

Enhanced Operator Services

Global Automatic Call Distribution is one of many examples of the way in which advanced business telecommunications services could allow a global distribution of jobs. Another example is in the area of operator assistance.

The technology available today makes it possible to greatly expand the concept of an "operator". The "operator" should be viewed as an expert consultant, who could offer many kinds of "consulting" services between two or more persons engaged in a telephone conversation. For example, the "operator as a translator" is a service which has been introduced in the USA.

Language translation is only one of many "expert" operator services which could be offered. Advanced telecommunications allows expert "consultants" to be located in developing countries just as easily as in developed countries. Such jobs will represent an important trend in the emerging information age.

3.2 Some Advanced Telecommunication Services Which Promote Business Efficiency

Audio Conferencing

Communications services which enable people in business to make more efficient use of their time are particularly important. To give an example, the one to two hour audio teleconference is becoming one of the most common kinds of meetings in many companies in North America. Documents required are distributed to all participants by facsimile and/or electronic mail shortly before the meeting (and sometimes during the meeting).

The payoff in business efficiency has made this a way of life for many businesses which operate in multiple locations. In terms of direct cost for the long distance telephone calls, these meetings will usually cost US$100-300 - usually less than the travel within North America would cost for only one of the participants. The equipment required is also relatively inexpensive. Some companies own conference bridges which can accommodate up to 96 people simultaneously in multiple conferences ranging from three to 96 persons. But audio conference bridges in the public networks are making this a service which is affordable even by smaller companies which cannot afford to own their teleconference bridge.

Audio teleconferencing enables people to work together, regardless of where they are located. This allows organizations to be structured more efficiently. People don't have to be moved to a central location. And advanced telecommunications services are less costly to implement, than building airports.

This has important implications for developing countries. If a developing country has advanced telecommunications, it becomes possible for multinational business to locate jobs in those developing countries. The kinds of jobs involved are those which do not depend on building expensive factories. And developing countries have many intelligent people with the skills required or who can acquire the skills.

Other Services Which Promote Business Efficiency

Some other examples of business telecommunication services which improve business efficiency include voice and text messaging, transaction validation and authorization, fast call set up, calling name display, and corporate dialing plans.

The business efficiencies available from text messaging (e-mail) and voice messaging have been discussed extensively in the literature and need not be repeated here. The benefits of transaction validation and authorization are so important that they have already been widely implemented and accepted, for example through networks of Automatic Teller Machines.

Fast call set up overcomes the long time required to set up calls. Even international calls are set up in less than one second. To human perception, the phone on the other end of the call begins ringing as soon as the last digit of the call is entered. This kind of speed results in efficiencies for everyone - for the telephone company, for the business making the call, and for the individuals involved. Slow call set up, coupled with a poor call completion rate creates serious inefficiencies in business.

Calling name display/calling number display is widely deployed in some private networks today. The service allows screening of incoming calls, to decide whether to answer or to let a secretary or a voice messaging system answer, providing greater efficiencies in the business day.

Corporate dialing plans are another important mechanism for facilitating information collection and dissemination. Communications are made more efficient by eliminating the need to look up city codes and country codes

As the world economy shifts to the information age, it is imperative that developing countries of Asia/Pacific implement advanced business telecommunication services now, so they can compete in the global economy.

4. NEW SERVICES AND JOB CREATION

4.1 Industry Sectors Which Will Benefit from Advanced Telecommunications Services

Advanced telecommunication facilities are a prerequisite for business promotion which has an immediate impact on job creation - including self employment. The role of telecommunications in providing the essential infrastructure for economic growth is now well understood, but its important contribution in developing various other sectors has mostly remained unfathomed and under recognized.

Telecommunication provides a vast reservoir of undertapped potential in improving the productivity of many job generating sectors like transport, banking, shipping, warehousing, trade and commerce, tourism, agriculture and dairy products, exploitation of natural resources and several others.

In all these activities, telecommunication services create more business potential in two ways - first by fueling the growth of the businesses which they serve and then by creating more opportunities through the growth of the telecommunication sector itself. Both these factors contribute to a multiplier effect. In many countries, the telecommunication sector continues to be one of the largest employers, in spite of the fact that it has always been a 'state of the art,' hi-tech sector.

Telecommunication also opens new avenues for job creation and job distribution in the intellectual property domain. With the introduction of many new services and facilities, there will be several job transfers and job upgrades as well. However, all these activities need efforts for their proper coordination , and, of course, an acumen for their fruitful utilization.

Let us take the example of a rather new field - Distance Education. The percentage of literacy in some countries of the Asia-Pacific region is even less than 20%. Telecommunication can provide a tremendous boost to the program of Distance Learning and will create several jobs in the telecommunication and education sectors. This will be in addition to the jobs which the improved skills will bring to the learners.

Development of telecommunications services in both private and government sectors will create jobs in telecommunication training covering not only the actual instruction but also other support activities like art work, documentation, audio-visual aids, video filming, etc.

The tourism sector has immense potential for creating several opporutunities for telecom related personnel in such wide ranging areas as aviation, transport, hotels and other support services like advertising, video filming, etc. Imagine setting up a telecom business center at each important tourist location, each rental car having a mobile telephone and each travel agency using a number of mobile telephones. The marketing of mobile telephones itself will create many jobs.

4.2 Current Status and Expectations

The development of a particular type of service will depend upon the quantum and variety of business applications in a city and in a country. Highly developed networks like those in Australia, Hong Kong, Japan, Republic of Korea, Singapore, etc. provide good opportunities for services like E-mail, EDI, video/audio conferencing, etc. India offers excellent opportunities for growth in software related communications. Malaysia, Indonesia and Thailand are using data networks for business related information. Socio-economic applications of telecommunications are an urgent need in all the developing countries of the Asia-Pacific region.

Appendix 1 gives an idea of the current situation with regard to implementation of advanced telecommunication services in many countries across Asia/Pacific and their likely impact on job potential on a country by country basis.

In addition to the impact within countries on an individuals basis, there is an opportunity for countries to benefit from the telecommunication requirements of large multinational corporations. These corporations need enhanced services, and can pay premium revenues for them. These corporations became accustomed in the 1980s to advanced telecommunications features and services available domestically on private networks and virtual networks. Now they want the same

another part of the revenue goes to pay for the Intelligent Network equipment.

5.3 Details of the Approach

The cost of equipping all switches in a national network to deliver new services has made it impossible for public networks to offer many of the features and services discussed in Section 3. The Intelligent Network approach makes it unnecessary to implement the services on every switch in the network. A key enabling technology is the combination of ISDN and CCITT Number 7 Signalling. Interworking between ISDN and CCITT Number 7 Signaling will eventually make it possible to reach the services at one or a few central locations where the Service Control Points (SCPs) are located from everywhere in the basic network.

ISDN implementations and implementation of CCITT Number 7 Signalling usually take place first in and between the major business centers of a country. This is where the Intelligent Network overlay should be implemented. A beginning is made by identifying appropriate business sectors and connecting their concerned centers. Intelligent call routing and call transfers can take advantage of the time difference in the busy hour traffics of different places and generate more revenue, together with more work - a happy situation in which every player wins.

In some cases, the most appropriate path is for a carrier to implement a bypass of its own network. This may be in the form of an international gateway which also provides enhanced business services, including global networking services. Or it may be a tandem network node which is co-located with a digital international gateway. It may even be a nearby central exchange.

Whether the Intelligent Network Services Switching Point (SSP) function is in the international gateway, in a tandem node adjacent to it, or in a nearby central exchange, a Services Control Point (SCP) will be associated with it. Advanced business services will be provided from the SCP. Depending on the level of signaling available in the existing network, businesses may initially be connected directly to the SSP. The choice of where to locate an SSP: in the international gateway, in a nearby tandem switch, or in a local central exchange may be further complicated by constraints associated with regulation or deregulation.

As discussed above, some of those revenues derived from advanced telecommunication services can be used to upgrade the existing network with ISDN and CCITT Number 7. As the existing network is upgraded, the advanced services can be made available to an increasing number of businesses, accessing the services in the overlay network through the upgraded basic network, using ISDN/CCITT Number 7 signaling. And, as the basic network continues to be upgraded, the conversion of the entire existing network to an all digital, ISDN/CCITT Number 7 base will be speeded up. Traffic requirements and regulatory requirements are some of the many constraints which will dictate the resulting network topology, which can vary substantially from one country to another.

5.4 Strengthening Regional Services

The first phase can be started with the networking of selected metropolitan areas, and in subsequent phases private networks can be interlinked. However, it is essential to strengthen sub regional, inter regional, intra regional and inter services cooperation for successful implementation of the programs.

Some business sectors, which are not key within a single country, will become important when they are considered on a regional basis. In many cases, CCITT Number 7 Signalling and ISDN will be available first in international gateways. These factors make it important to consider implementation of advanced telecommunications services for business sectors which will prove in economically on a regional basis, but not on a domestic basis. This implies some sharing of SCPs by carriers in several countries, which will raise complex policy issues. Nevertheless, it is important to make a start on regional services. "Regional" could mean areas like the ASEAN countries only in some cases, but it could mean all of Asia/Pacific in other cases.

5.5 Positioning for Broadband Services

The digital intelligent network overlay approach provides excellent positioning for implementation of broadband services on digital optical fiber communication paths and through broadband switches. The capabilities of the Service Switching Point (SSP), shown as the Overlay Node in Figure 1, will evolve gracefully to handle the new wideband and broadband services which are beginning to appear. For example, the overlay network is a logical point to implement video teleconference services as an extension to audio teleconference services. As broadband access capabilities are built into the SSPs, a host of other broadband communication services is forecast to emerge during the mid-1990s.

The same industries and metropolitan centers which will benefit first from the narrowband advanced telecommunication services discussed earlier, will be the ones to first use the new wideband and broadband communication services. Digital optical fiber can be extended to these industries first, and their initial connection will be the overlay network. This will provide the fastest mechanism for actually implementing wideband and broadband services. And these industries are the most likely to be able to pay for the broadband services, just as they are the most likely to pay for narrowband services today.

features on a global basis in the 1990s. A few examples of the businesses which are active in global networking today include aerospace, manufacturing, finance and banking, transportation, and tourism.

Many nations have already recognized that providing advanced telecommunications to large multinational businesses will attract those businesses to establish a significant presence in their country. Conversely, these same businesses will not locate major activities in countries which will not support their requirements for advanced communications. As a result, many developing countries are making early provision of enhanced business communication services a matter of high priority in national development policy.

5. AN OPTION FOR IMPLEMENTING ADVANCED SERVICES

5.1 Advanced Services Versus The Basic Network

The goals of telecommunications network development must be to implement a ubiquitous network to meet the basic communication requirements of society, and, **concurrently**, to provide an advanced network to meet the business communications requirements of industry. These goals are viewed as contradictory by some, but are gradually being recognized by others as complementary.

Conventional wisdom says that a developing country must first implement a full nationwide digital network infrastructure. Only after that is accomplished can the kinds of advanced business services discussed above be implemented. Unfortunately, that strategy will leave developing countries in a "catch-up mode," because many do not have the hard currency needed to import the digital equipment, and few can afford to develop the equipment themselves. Meanwhile, business in developing countries will remain less competitive than it's counterparts in the developed world, perpetuating an already difficult situation.

5.2 The Overlay Network Option

Wide scale implementation of an advanced digital network is hampered by financial constraints and even by limitations on how fast equipment may be written off. In many cases, digital equipment (and even some analog) cannot be replaced yet because it still has a significant useful life, from a financial point of view. The solution to the dilemma is to implement a business services network overlay (Fig 1.).

One purpose of a business services digital overlay network is to provide advanced services to improve business efficiency. A second purpose is to generate the hard currency so badly needed for more rapid implementation of the basic digital network.

Improving Business Efficiency

Advanced telecommunication services tailored to the business environment of a country, can be implemented efficiently in an intelligent network overlay to the basic network. The kinds of services discussed above, and many others can be implemented in the overlay, without disturbing the basic network.

Digital Overlay Network Concept

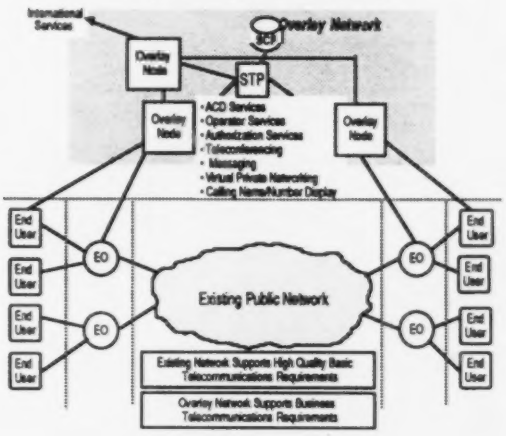

Figure 1

In an intelligent network overlay, services are implemented in a Services Control Point (SCP) (Fig. 1). This is a significant change from implementing services in every switch in the basic network, which is the only option available to most administrations today. An Intelligent Network Service Maintenance System (SMS) (not shown), greatly simplifies Operations, Administration, Maintenance and Provisioning (OAMP) for the advanced services, and reduces costs in all of these areas.

An Intelligent Network Services Creation Environment will make it possible for carriers to implement services specifically tailored to the way business is done in their own regions/countries. This will maximize the benefit of the services to improved business efficiency in each country.

Generating Hard Currency to Improve the Basic Network.

Multinational corporations and major domestic businesses will be willing to pay premium revenues for advanced telecommunications services which improve their efficiency in measurable terms. Typically, the cost of equipment on which enhanced business services are implemented can be amortized within five years, out of business revenues generated from services provided on that equipment. Some revenue from advanced business services can be used to pay for more rapid implementation of the basic digital network while

6. CONCLUSIONS

By examining some specific services, we have seen how advanced telecommunications services improve business efficiency and create new jobs in the economies of the countries which implement the services

Through examination of some specific industry sectors, it is clear that the variety of sectors which will benefit from advanced telecommunication services is much wider than has generally been appreciated

Development of particular services varies widely, but many new services have already been implemented across the Asia/Pacific region. This is already having a positive impact on the quantity and quality of new jobs being created throughout the region.

An intelligent network overlay represents an effective and affordable option for early implementation of advanced telecommunications services. And this option can also speed up implementation of the basic digital network infrastructure needed by every country.

The result will be an environment in which everyone wins - business becomes more efficient , the national network becomes an all digital network which is more reliable and less costly to maintain, and business becomes more responsive to its customers.

Appendix 1 NEW TELECOM SERVICES IN SOME COUNTRIES OF ASIA-PACIFIC REGION AND THEIR LIKELY IMPACT ON JOB POTENTIAL

	Country	New Services	Impacts
1.	Afghanistan	Present emphasis is on developing the basic services. VAS are likely to be introduced subsequently	More jobs are likely to be created in the government sector and in construction industry
2.	Australia	Mobile, Paging and several other services increasing in popularity. Electronic Funds Transfer at Point of Sale (EFTPOS) using Australian Packet Switched Network (AUSTPAC) is being used by several major banks in Australia.	Growth of hi-tech business is likely to create more job avenues including self employment opportunities in future.
3.	Bangladesh	402 Sub-district Hqs. being connected to respective district headquarters. After completion of the work, BTTB intends to extend computer service terminated into rural centers for banking, administration, agriculture and other social service sectors	Creation of jobs in telecom and other concerned sectors. Creation of more jobs in building construction, installation, and computer operation and servicing sectors.
4.	Brunei	Mobile and Paging Services have already been introduced. Telecommunication facilities are being developed rapidly and are finding increasing application in the business sector.	Development of telecommunication and information sectors will create more avenues for employment including self employment.
5.	Peoples Republic of China	The number of users in China's Packet Switching Network (CNPAC) has increased rapidly. About 2/3rd of CNPAC traffic volume is from foreign trade organizations in Beijing (mainly Mailbox and information retrieval services, derived from databases in the USA). High priority will be given for popularization of E-Mail and EDI.	More jobs in research, development and service sectors. Also creates more business and development prospects in other countries.
6.	India	India's software expertise is used in the USA through dedicated satellite links. Voice mail, videotext, fax, paging, PSTN, GPSS, Satellite Based Remote Area Message Network, E Mail specialized data network are already in use. Massive program for development of Rural Communications has been launched. Telephone booths operated by disabled persons are already a big success.	Several new avenues in government, public and private sectors covering research and development, manufacturing, servicing and procurement, software applications, etc., have been created.
7.	Indonesia	New services such as Packet Switching Public Data Network, Fax, Mobile Services, Electronic Mail, Pager, etc. have been introduced. Liberalization of non basic services has already begun. Telecom service and manufacturing sectors are growing rapidly.	New job opportunities with increase in variety and number of services.
8.	Islamic Republic of Iran	Basic services being augmented and new services planned for phased introduction. Increasing telecom applications providing good boost to the business sector.	Developments in telecom and business sector are likely to create more jobs in private sector.
9.	Japan	All kinds of research, manufacturing and service activities. Business growth through about 900 carriers.	Emergence and growth of information industry.

Appendix 1 (Cont'nd)

NEW TELECOM SERVICES IN SOME COUNTRIES OF ASIA-PACIFIC REGION AND THEIR LIKELY IMPACT ON JOB POTENTIAL

Country	New Services	Impacts
10. The Republic of Korea	VANs quite developed. Korea Telecom and DACOM are public common carriers. In addition there are 22 registered private VAN operators. The size of domestic VANs market was US$213 million in 1990, which is likely to grow to US$413 million in 1992.	More job opportunities due to the development of new services and high growth potential of business in the information sector.
11. Lao. PDR	The present priority is on developing basic services.	Increasing use of telecommunications will create more employment in future.
12. Malaysia	Packet switched (MAYPAC) and Circuit Switched (MAYCIS) data networks and Value Added Services like Videotex, Telemail, are growing steadily. Videotex services finding wide application. A joint venture co. with IBM (Malaysia) has been formed which will promote EDI and will also offer other services like E-Mail etc.	More self employment opportunities due to introduction of new kind of business Videotex impacting microcomputing, fishery information, shipping, flight information, on-line share price, real estate properties, drug/poison database, education, classified advertising.
13. Maldives	Many new services have been planned for introduction in a phased manner.	Likely increase in job avenues due to more telecom support to business.
14. Myanmar	There is a heavy demand for basic services. Value Added Services may be introduced at a later stage.	More employment in government sector due to increase in telecom services.
15. Nauru	Increased communication with the neighboring countries opens up new business avenues.	Likely increase in jobs due to increase in business activities.
16. Nepal	About 80% of the telephone lines are digitalized. International as well as domestic traffic has increased sharply. Leased circuits and telefax have already become popular. Introduction of other services also being planned shortly.	More jobs expected in government sector due to more development activities. Improved telecom facilities promoting use of computers in several areas, which will result in more job avenues.
17. Pakistan	Packet Switching Network introduced in 1990. Electronic Message handling services, Bulletin Board services and Data Base services are being planned.	Development of these services is likely to create more jobs in private sector.
18. Philippines	Cellular Mobile, Radio Paging, VSAT and several other services are being provided to the customers.	More jobs expected due to development of these services in the private sector.
19. Singapore	A Variety of New Services are provided. Value Added Services have been liberalized and are growing fast. Hi-tech applications have given a tremendous boost to business.	More employment opportunities in business sector and also more opportunities for self employment due to hi-tech applications in business. Hi-tech exhibition industry itself provides many job opportunities.
20. Sri Lanka	Liberalization and development of telecom service is underway. New services are being introduced in a phased manner.	Employment opportunities in private sector likely to increase through new telecommunications.
21. Thailand	Value Added Services such as Datanet, Videotext, Telebox, Faxcom, Voicemail, Mobile services, Infonet, etc., have grown rapidly.	Higher employment potential due to increased business activities in the private sector. Also due to massive expansion of telecom services, more jobs are expected in the government sector.
22. Vietnam	Data transmission centres in Hanoi and Ho Chi Minh City are serving customers in banks, import/export companies, government departments and news agencies. Other development plans are under various stages of implementation.	Increased job opportunities in private and government sectors.
23. Hong Kong	A variety of Value Added services is being provided to business and government users. Demand for these services goes on increasing.	Development of telecom facilities and the growth of business create more jobs in private sectors.
24. Cook Islands	Ambitious development plans have been prepared proposing the use of small INTELSAT DI-Satellite Earth Station using OTC DAMA Network for both national and international communications. Interconnection of islands will help implementation of development activities and growth of business.	More jobs due to rise in business and development activities.

RURAL TELECOMMUNICATIONS DEVELOPMENT
THE REA CONCEPT

James R. Underwood
Robert M. Engelbardt
Hicks & Ragland Engineering Co., Inc.
Honolulu, Hawaii USA

ABSTRACT

Developing countries continue to face difficulties in providing modern telecommunications services to rural areas because of high costs and low revenues. Incentives for the provider in the form of attractive investment loans and technical assistance could help. The successful U.S. REA telephone loan program is described as one possible solution.

1.0 INTRODUCTION

Few discussions on worldwide telecommunications development fail to mention the relatively slow progress on expanding and improving services to rural areas in many countries. The situation was strikingly illustrated in the 1984 Maitland Report's "Missing Link". Today, the great disparity in access to telephone service is still evident despite significant accomplishments in a number of developing countries during the last decade.

2.0 STATISTICS

While the traditional measurement of "telephones per hundred population" indicates substantial progress in some countries, the statistics often fail to reveal the true picture. The figures are normally averaged for the entire country, but most of the access lines are actually concentrated in the densely populated urban areas.

Let's assume, for example, that a country with an overall service penetration of less than one telephone per hundred persons increases this figure to five through a bold construction program. That would be a significant expansion; however, closer examination might reveal that the major cities exceed ten telephones per hundred, smaller urban areas have two to three per hundred with the rural areas remaining still unserved or with an unchanged fractional penetration level.

3.0 INVESTMENT IN RURAL AREAS

It is reasonable to expect that investment priorities for telecommunications facilities in developing countries will favor urban areas because this is where businesses are concentrated. Because commercial enterprises foster national economic competitiveness and attract foreign capital, their basic needs are first to be met. Most administrations face a difficult task securing sufficient funding just to meet the accelerating demand for service in cities despite the almost assured adequate return on investment. Thus, deferring activities in rural areas can be justified from an economic viewpoint.

The rural areas not only lack the economies of scale achievable in the cities, but they are beset by other adverse factors:

1) High system construction costs in widely scattered communities with comparatively low population densities often located in isolated places.

2) Higher operating expenses resulting from a lack of local skilled maintenance personnel and longer distances from supply centers.

3) Fewer businesses and less affluent inhabitants to generate additional revenues from long distance services.

4.0 PRIVATIZATION

In many countries, telecommunications services are provided by state owned and operated organizations staffed with government employees. Funding for expansion and modernization of facilities is often insufficient. Surplus earnings from operations are frequently diverted to other government functions. Despite their altruistic goals to provide nationwide universal service, few

government systems are able to adequately meet the requirements of their nation's rural areas.

The current trend towards privatization of government telephone systems, with all of its potential advantages, may not help improve rural area service unless incentives are provided for the private investor. Few, if any, businesses with normal profitability goals would conscientiously make substantial capital investments in areas where returns are marginal or, more typically, negative. For these reasons, governments may be concerned that privatization could further inhibit rural area development and universal service.

While the high cost - low revenue scenario alone might be sufficient to discourage many private operators from establishing rural telephone service, the additional problem of securing adequate financing at attractive interest rates could make the undertaking totally unfeasible. Reducing the high cost of installing facilities and increasing revenues in rural areas may be difficult to achieve but there are ways to make the financing of these projects more favorable, thus removing at least one major hardship.

The United States remains as the world's leading proponent of telecommunications privatization. Prior to the breakup of AT&T, thousands of small independent telephone operations were providing service to rural America. They ranged from tiny cooperatives serving small farm communities to medium sized companies with large territories, some of which included villages and towns. Today, the Regional Bell Operating Companies and GTE cover over 90% of the nation but many of the small independents still survive and continue to provide modern telecommunications services. The capability of these systems is equal and sometimes superior to their larger counterparts in some areas.

5.0 THE REA PROGRAM

The achievement of furnishing high quality, universally available and affordable telephone service to rural America is partly the result of a unique financing and technical assistance program established by the U.S. government under the Department of Agriculture. This agency is called the Rural Electrification Administration (REA) which, for over 40 years, has assisted more than 1,000 telephone companies to build, expand and modernize their systems in 46 states and six overseas territories. The borrowers' incentives include capital availability, lower interest rates and less demanding financial qualification requirements for loans as compared to commercial lenders.

REA was initially established as a source of loan funds and technical assistance for the provision of rural electric service. In 1949, its mission was expanded to extend similar benefits to rural telephone system operators. These companies and cooperatives average only about six subscribers per mile of telephone line with a median number of subscribers per borrower of around 2,400.

REA borrowers average more than 1,000 route miles per system with a total of $13 billion invested in facilities to serve their nearly six million subscribers. Although only 4.3% of all telephone subscribers in the U.S. derive telephone services from REA borrowers, they cover nearly 1.3 million square miles or around 37% of the nation's entire land expanse.

In many countries with substantial rural areas, the situation is little different from the U.S. The two factors - high cost and low population density - tend to inhibit effective rural telecommunications development without some type of financial assistance and other incentives for the service providers.

To date, the REA telephone loan program has approved debt financing totaling nearly $10 billion. About $5 billion in principal and interest have been repaid. Borrower loan repayments nearly equal REA cash outlays; therefore, on a cash basis, the program is almost self-sustaining. The incremental subsidy cost to the U.S. government for all telephone loans in fiscal 1990 was under $7 million, while the cost of administering the REA telephone loan program was almost as minimal.

Technical oversight such as installation practices and procedures, testing and evaluation of equipment and contract documents are provided at no cost to REA borrowers. In return, they must adhere to certain technical design standards and construction procedures to assure that REA financed telephone systems will provide high quality and reliable service. Stringent administrative procedures guarantee that REA funds will only be used for approved purposes.

The following provides some details of the REA telephone loan program in the U.S. Other countries may want to consider using this program as a model for developing their own conception of government sponsored incentives for private companies and public service corporations tasked with installing or modernizing rural telephone facilities.

6.0 REA's PHILOSOPHY

REA's philosophy is based on service, rather than the generation of profit. That is, profit is the result of providing service instead of the frequently expressed belief that service is the result of profit. REA's two primary concerns are service to the subscriber and debt service on the loan. While they recognize that a business must make a profit to survive, there is no emphasis on maximizing profit.

REA's service goals are expressed in several of its fundamental policies:

Area Coverage - With minor exceptions, all subscribers within a borrower's service area will be provided telephone service without additional charges for construction regardless of the cost and difficulty of bringing facilities to the subscriber.

Service Rates - All subscribers will pay the same rate for the lowest level of basic telephone service provided, typically one-party.

Favorable Loan Terms - Loans will be long term, up to 35 years with attractive interest rates and no prepayment penalties on most loans.

Construction Standards - Standardized specifications, construction procedures and contractual documents will be used on all REA financed projects.

List of Materials - REA financed projects must use proven equipment and materials that meet the standards for high quality service. REA maintains a list of approved items which have undergone laboratory analysis and field testing.

Engineering and Management Assistance - REA assists the borrowers in developing a qualified and competent staff to handle the engineering, accounting and management functions and encourages the use of approved consultants to augment the staff.

7.0 REA's LOAN PROGRAMS

The REA telephone loan program currently has three methods for financing its borrowers' projects:

Insured loans - Direct loans from REA at 5% interest with a term not exceeding 35 years.

Rural Telephone Bank loans - Variable interest rates on loans up to 35 years.

Guaranteed loans - 100% guarantee by REA to the lender on repayment of principal and interest for loans obtained from commercial financing sources.

The various REA loan programs are continuously monitored by the U.S. government which periodically enacts legislation and rule changes to assure that the objectives of the program are being met.

8.0 GENERAL PROCEDURES

REA's procedures are designed to protect the lender, borrower, contractors and suppliers. They also require consistency to promote fair and honest treatment of all parties.

The REA loan process is divided into two basic steps. The first is the pre-loan process which includes preparing a subscriber forecast, system design plans, loan agreements and supporting documentation for submission to REA. Following approval of the loan, the second step, or post-loan activities, covers implementation and operation of the project.

The following overview covers the major components of an REA loan:

8.1 Loan Agreements

All REA loan agreements must contractually ensure that the objectives of providing service and achieving the purposes of the loan are being met. Certain safeguards are therefore required in the loan agreements:

1) The lender must have the power to enforce the provisions of the loan.

2) If the loan objectives are not being met, the lender has the power to take control of the borrower's operations.

3) Appropriate security measures must be taken to protect the lender's interests.

4) REA Loan funds must be maintained in separate accounts and disbursed only when and to whom REA directs.

8.2 Design Procedures

REA has established system design standards and procedures to ensure that modern, compatible, high quality and reliable service will be provided to subscribers on projects which use its loan funds. All borrowers and their consultants are provided with a comprehensive series of REA technical publications covering the approved design and construction procedures for rural telephone systems. The primary areas addressed are:

1) Switching and transmission standards.

2) Electrical protection requirements.

3) System expendability to meet new service demands.

4) System flexibility to provide new service features.

8.3 Construction Planning

REA has prepared design and construction specifications to assure that equipment manufacturers and contractors tasked with installation and construction will build telephone systems that meet the desired objectives. These cover:

1) Standardized specifications for switching and transmission equipment, cables, hardware, etc.

2) Testing procedures to assure that performance specifications are met.

8.4 Contracts

REA provides standard contract forms to ensure that the borrowers as well as the suppliers and contractors are protected and that the system will be implemented on a timely basis in accordance with specifications. Contracts typically include:

1) Bid bonds.

2) Performance bonds.

3) Insurance requirements.

4) Supplier and contractor payment terms.

5) Warranty provisions.

8.5 Bidding

REA requires strict adherence to standardized bidding procedures to ensure that all qualified bidders are treated equably. Competitive bidding procedures include:

1) Prequalification of bidders.

2) Pre-bid conferences.

3) Bid evaluation for responsiveness to specifications and inclusion of all pertinent documents in the bid package.

8.6 Construction Procedures

To ensure acceptable contractor performance and adherence to specifications, REA requires that all construction and installation work be monitored and inspected. This can be performed either by a qualified independent consulting firm or the borrower's staff if they are qualified and approved by REA to perform the work. Major activities include:

1) Pre-construction conferences with appropriate documentation.

2) Review of materials to be used on the project.

3) Field inspections during construction.

4) Acceptance testing.

5) Documentation of "as built" system.

8.7 Monitoring and Audits

REA monitors the borrower's financial strength and requires fiscal controls to assure its overall viability and capability of repaying the loan. The items reviewed include:

1) Operating reports and year end financial statements.

2) Insurance coverage.

3) Service trouble reports.

4) Compliance with appropriate laws associated with the loan agreement.

5) Annual audits conducted by a CPA firm.

6) Periodic audits of loan fund expenditures by REA field staff.

8.8 Use of Consultants

Many REA borrowers, particularly those without large engineering and construction staffs, use engineering consultants for some or all elements of the loan program. Frequently, these firms are requested to handle everything from preparation of loan request documents to final inspection and acceptance of the system. Consulting firms working with REA financed projects should have the following qualifications:

1) No business affiliation with any equipment manufacturer, supplier or contractor.

2) A qualified staff of professional engineers and technical personnel experienced in all telephone system technologies.

3) Familiarity with REA technical and administrative procedures and access to all REA publications.

4) Availability of experienced field personnel for project coordination, inspection and testing of all installation and construction.

9.0 CONCLUSION

The success of the REA program can be attributed to its basic goal of service. The ultimate beneficiaries of the program are the users who might otherwise be deprived of an essential benefit to health, safety, welfare and quality of life simply because they reside in rural areas. The nation as a whole also profits because rural area development stimulates business activity, creates employment and produces revenues.

While financial incentives alone could be sufficient for encouraging service providers to invest in rural telecommunications facilities, other benefits of the program should not be underestimated. For example, the standards and specifications for design and construction will ensure optimum service quality and efficient use of funds. The management and operational oversight requirements assure overall viability. Accounting and fiscal controls protect the lender. Loan agreements between the borrowers and the lender ensure compliance with the lender's policies and require that the funds be used only for the provision of service.

In the U.S., the REA telephone loan program is administered by the government and the lending agency uses government funds. In other countries, a similar program could be carried out by non-governmental entities such as development banks or private financial institutions. All or parts of the program could be used depending on the overall situation in particular areas. The process could be customized to fit the unique requirements of a particular country and include the key ingredients of capital availability, standardized loan contracts and agreements, technical standards, policies, procedures, program monitoring and auditing.

REA's telephone loan program has proven itself in the U.S. for many decades. Rural America's telecommunications services are unsurpassed in the world, but the program is still needed and utilized today. New telecommunications services, essential for rural economic development, require infrastructure improvement through deployment of new technology. Recognizing this, industry and government experts alike believe there will always be a need for REA's capital and technical assistance.

OPEN NETWORK ARCHITECTURE FOR CELLULAR SYSTEMS

Jack M. Scanlon
Motorola Inc.
Arlington Heights, Il. U.S.A.

ABSTRACT

The first generation of cellular systems was introduced using proprietary architectures--different from each manufacturer. Second generation cellular architectures are now being introduced coincident with adopting digital techniques at the air interface.

Two digital specifications, GSM and DECT 1800 specify an entire open systems architecture which, for the first time, permits mixing vendor infrastructure components to achieve a complete cellular system providing operators a new level of vendor independence and competitive prices. Motorola has embraced this open system's revolution and is extending it to support other worldwide digital standards. Cost effective implementation of PCN/PCS will require further evolution of these standards to permit sharing of existing PSTN infrastructure to reduce PCN/PCS infrastructure cost and implementation intervals. Experimental trials of several variations of these concepts are expected to take place in 1992.

INTRODUCTION

For landline telephony, the era of proprietary, single vendor, infrastructure systems, typically by country or region, came to a close in the 80's facilitated by the rapid adoption of SS7 technology and worldwide deregulation. Indeed, in many countries, it is now typical that local loop operators source two or three switch and Intelligent Network (IN) vendors and that multiple long distance operators interface with the local carriers utilizing a wide diversity of vendors. It is also useful to recall, that the equivalent of the Air Interface specification for the local loop, the Tip/Ring interface, was for the most part, closed to terminal competition in landline telephony until regulatory decisions like Carter phone and its international equivalents were issued during the 70's.

Initial cellular systems designed in the early 80's adopted the prevailing open standards behavior of landline at that time. That is, only the air interface or terminal specification was standardized and "open". All initial infrastructure designs were completely different and totally proprietary to each vendor. This forced operators to select a single vendor for their cellular infrastructure reducing the operator's long term leverage on prices and, effectively, forcing the operator to make a long term technology bet, in a dynamic, cellular technology, which is still in its infancy.

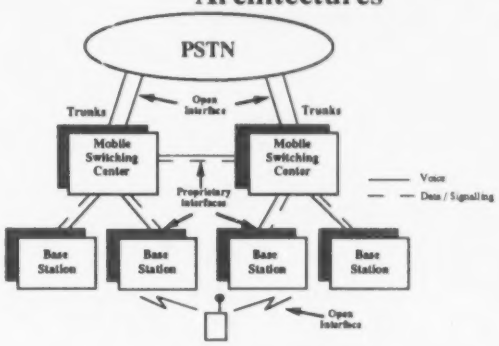
Significant progress has been made in some markets in "opening up" the infrastructure systems design as second generation, digital cellular has been specified. GSM is the best example which now is in early deployment and is already beginning to provide operators with an entirely new level of vendor independence and price competitiveness. Motorola is extending the concepts pioneered in GSM to propagate open interfaces across worldwide cellular and PCN standards.

INITIAL CELLULAR SYSTEMS

Figure 1 illustrates the architecture of the initial cellular infrastructure systems.

Figure 1

Initial Cellular Infrastructure Architectures



Each vendor's offer was proprietary, providing a complete infrastructure system from cells to switching. The key interfaces, that is between the base station and the switch and the switch to switch roaming protocols were totally proprietary from each vendor. The only "open" interface was the air interface specification between the subscriber unit and the base station and the trunk interface between the Mobile Switching Center (MSC) and the PSTN. MSC's were software modifications to existing switches with special mobility management and cell maintenance software imbedded in the proprietary switch. Once an operator selected a vendor, virtually no future choice existed to incorporate innovations from other vendors as cellular technology evolved. The only exception was at the subscriber unit level. As a consequence, while the subscriber unit prices (U.S) have declined approximately 20% per year due to intense competition from more than 20 competitors, voice channel prices have remained more or less constant. It is the author's opinion that this lack of

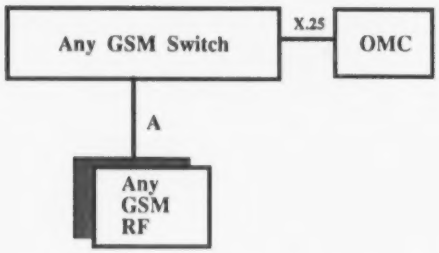
continuing competition within infrastructure, especially at the level of the voice channel, will keep infrastructure prices high and offer operators no incentive to add the new, more casual user to their network which is fundamental to further market penetration and, hence, industry growth. The remedy is to open up the key interfaces in the cellular infrastructure, particularly the base station to switch interface, generating competition at the voice channel level similar to what occurred with the standardization of the air interface at the subscriber unit level.

OPEN INFRASTRUCTURE-PROGRESS TO DATE

The GSM specification, at both 900 MHZ and 1800 MHZ, is by far the most mature in opening up key infrastructure interfaces. Figure 2 illustrates the GSM infrastructure specification which defines an open standard, "A", between the base station and switch and subtracts the cellular operations and maintenance function (OMC) from the switch. This permits the operators, for the first time, to separately select a switch vendor from a cell (Base Station & OMC) vendor, generating competition for voice channel prices.

Figure 2

GSM Architecture



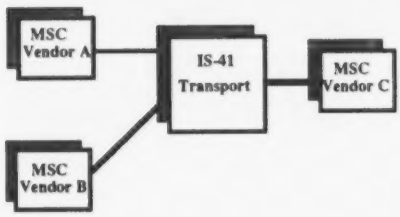
To date, Motorola is the only GSM infrastructure supplier which bids GSM cells (Base Stations & OMC) independent of the switch with the commitment to integrate the system with the switch vendor chosen by the operator. For example, GSM cellular systems utilizing Motorola cells and Siemens switches will be deployed in Sweden and United Kingdom late this year. In addition "A" interface testing and configuration agreements have been established with a number of other GSM switch vendors expanding the operator's choice of switch and cells.

As a consequence of adopting this open infrastructure architecture, GSM operators have seen a decline in prices per voice channel of more than 20% during the last year - a price learning curve which begins to approximate one that cellular subscriber units have been on for sometime.

Progress in open infrastructure standards in non-GSM markets has, to date, been limited. For the AMPS standard, the only notable advance is the introduction of the IS-41 specification which permits subscribers on one vendor's infrastructure system to roam to another. IS-41 as illustrated in Figure 3 is in the very early stages of introduction in the U.S. and will require a number of future revisions to match the feature/functionality of today's proprietary roaming protocols such as Motorola's DMX. IS-41 is an important first step in moving towards open architecture for the AMPS standard.

Figure 3

IS-41 Networking

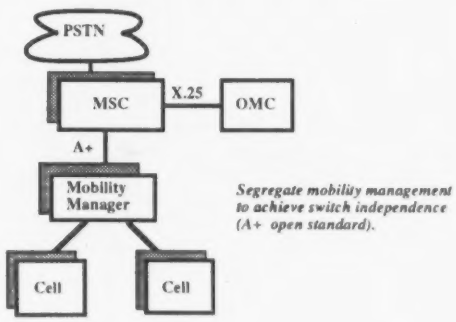


Digital specifications, other than GSM, such as USDC, CDMA, and Japan Digital do not yet accommodate open infrastructure interfaces although operator interest and pressure are growing in these areas. As was the experience in Europe with GSM, establishing these standards will require strong support of the operators.

Motorola is pioneering the introduction of open interfaces in these markets by evolving the GSM A specification to A+ where the "+" refers to modification required to accommodate the particular air interface specifications. Figure 4 illustrates this model of Motorola's Open Network Architecture (ONA).

Figure 4

Motorola ONA for Cellular



Here, in addition to the subtraction of cellular maintenance (OMC) from the switch as per the GSM specification, the mobility management (handoff, location registers, billing) is also subtracted from the switch and relegated to a mobility manager - a high capacity fault tolerant computer.

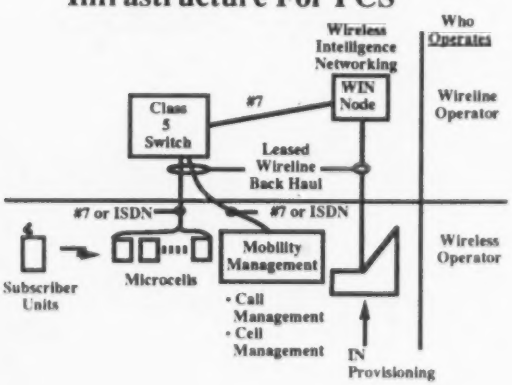
This architecture has a number of advantages to the operator. First, like GSM, it permits the independent selection of a switch and cell by the operators from those cell and switch vendors who adopt the A+ interface. Second, this architecture outboards some of the critical mobility management function from the switch to a computing platform which permits the introduction of new cellular functionality to be more independent of switch generic releases. In addition, this approach outboards some of the critical real-time intensive processing of cellular from the switch. This advantage is potentially a major one for operators since it places some of the critical busy hour attempt parameter of their system on a computer technology learning curve (typically 2X capacity every 18 months) versus a much slower switching capacity learning curve. This is especially important with the adoption of new digital air interface technologies which can require 2-3X switch processing real-time as their predecessor analog technologies.

PCN/PCS AND ONA

To this point in the discussion, the importance of ONA to cellular has been outlined for cellular. In a cellular topology relatively few high RF-powered cells are required for broad coverage, and hence, separate switching and cell site to switch transmission facilities can continue to be justified. However, for PCN/PCS, where the number of cells is expected to be 4-100X that of cellular (depending on the spectrum) the expense of totally separate transmission and switching infrastructure is prohibitive both in capital outlay and time to market. Therefore, the adoption of further open interfaces to "piggy-back" on existing infrastructure is, in the author's opinion, essential for PCN/PCS to be attractive. Figure 5 illustrates one approach, currently being discussed in the U.S.A., which permits a PCS service to be positioned on the existing PSTN infrastructure.

Figure 5

Utilizing Wireline Infrastructure For PCS



Here, the wireline local operating company provides both the microcell back haul for PCN/PCS and the switching. The wireless operator maintains operational independence by controlling the mobility manager, determining wireless feature functionality such as hand-off, roaming, customer features and billing. In addition, the wireless operator controls the OMC functionality to maintain cell sites and has an Intelligent Network (IN) provisioning capability to the PSTN to enable call routing between landline and wireless. This arrangement is economically attractive to the wireless operator only if the wireline operator provides attractive tariff rates for back-haul, virtual switching and IN functions. Considerable market pressures exist to achieve competitive tariff rates since the alternative for the wireline operator is to lose their 'dial tone' franchise for a considerable percentage of their users. Arrangements similar to this have been proposed in earlier literature (1) and will be utilized in Japan's experimental trial of handi-phone. (2)

SUMMARY

The proprietary infrastructure period for cellular is rapidly coming to a close. GSM has pioneered an open infrastructure specification which has already provided operators with a new level of vendor flexibility and intense competition at the voice channel level. Motorola is currently the only vendor which is actively propagating this standard extending it to other markets. The attractiveness of this arrangement to the operators makes its ultimate adoption inevitable. Further, PCN/PCS economics requires further evolution of open infrastructure interfaces in order to piggy-back on existing infrastructures. The day will come when a cell can be selected with a high degree of freedom. The resultant competition could put voice channel prices on about the same annual learning curve as subscriber unit prices and stimulate the growth of the entire industry.

CELLULAR SYSTEMS TECHNOLOGY: NARROW BAND DEVELOPMENT AND DIGITALLY ENHANCED CELLULAR SERVICES

Michael Kotzin and John Kay
Motorola, Inc.
Cellular Infrastructure Group
Arlington Heights, Il. USA

Abstract

Due to rapid subscriber growth, providing adequate cellular capacity has become a critical problem, especially in major metropolitan areas. Several proposed digital solutions are in the draft specification stage and will require significant additional validation, testing, and development time. A narrowband extension of the existing analog cellular AMPS system, termed NAMPS, is proposed to provide a technology bridge between AMPS and an ultimately adopted digital approach. The NAMPS approach affords immediate spectrum relief as well as a continuous digital messaging stream which provides some significant service and performance benefits to the user and operator alike. The technology is already tested and proven, providing an economical and low risk interim solution. Commercial subscriber equipment is already available to begin the crucial preloading phase.

Introduction

Cellular subscriber growth in the past five years has been nothing less than spectacular. Estimates now cite a sustained realistic growth opportunity of about 35%, while in recent years annual subscriber growth has peaked at numbers even twice this value.

Major metropolitan areas have felt the strain of this rapid subscriber growth. For the most part, cellular system operators have been able to keep up with this growth by adding channels. Since cellular systems are limited in allocated spectrum (and therefore the total number of available channels), subscribers in high density locations have been able to be accommodated only through careful application of geographic reuse, i.e. cell splitting.

However, limits in cell splitting are already being reached. In mature cellular systems, where capacity is most needed, the ability to find appropriate cell site locations has become problematic. Placement accuracy needed for co-channel reuse protection increases inversely with the desired cell size. Furthermore, when appropriate sites can be found, they can be prohibitively expensive.

Despite the operators' attempts at keeping up with demand, it is not uncommon during peak hours for users to be blocked from placing calls due to lack of available voice channels. Also, the greater amount of reused channels has increased the opportunity for interference which produces degraded audio quality and in extreme cases, dropped calls.

Users' expectations about cellular have evolved significantly. Initially offering essentially "car" telephone service, cellular has now evolved to providing personal communications. This is evidenced by the continuing trend away from mobile subscriber units towards portable devices which are now approaching 50% of cellular subscriber radio sales. The personal aspect of cellular will no doubt be enhanced as the cost, size, and weight of the physical radio continues to reduce and service availability, particularly in-building, becomes more ubiquitous.

Ultimate Digital Proposals

Several proposals have been offered for dealing with the cited capacity problems. These proposals have principally focussed on the radio air interface protocol. One proposal, for example, is a TDMA solution and provides, at the outset, three users for each AMPS channel exchanged. Another proposal utilizes wideband direct sequence CDMA and claims to offer potentially 10 to 20 times the capacity over conventional analog cellular. A considerable amount of controversy still surrounds the decision between these and other offered proposals. The discussion involves technical feasibility, merit, and cost for each approach as well as subscriber implementation viability.

While draft standards exist for both of these above proposals, there has yet to be any significant field or market trial for either technology. Considering the radical departure of these techniques from that currently utilized with AMPS, or any other existing cellular systems worldwide, considerable care in the adoption process should be exercised.

The problem currently facing cellular operators and manufacturers is making a final decision on which proposed solution to ultimately embrace. Limited testing for both proposals is in process but considerably more testing is still necessary. The original AMPS specification went through extensive trials in Chicago and Washington / Baltimore to validate the specification. This evaluation involved some 2500 subscriber units and uncovered some 8000 problems. The GSM digital cellular system development in Europe is likewise following a specification development schedule having provisions for adequate testing. This plan included a validation exercise to establish specification consistency, correctness, and completeness. Furthermore, it provides for a pre-operational phase for final testing prior to commercial release.

Without a doubt, equipment suppliers will be particularly cautious before totally embracing any final solution. Any selected approach needs overall industry acceptance. Subscribers are accustomed to a particular size/weight package and will not pay significantly more without some apparent benefits. Any successful deployment of equipment will demand some significant movement down the development experience curves to achieve the necessary cost reductions and capabilities. Achieving the minimum expectation levels for subscribers with so much new technology will require considerable up front investment. There will be some hesitancy to move forward too rapidly so that necessary specification changes can be found in a timely manner and not cause a major development redirection. Therefore, there is a strong desire to find low risk approaches that would avoid any opportunity for operational problems.

The radio technology required to implement any fully digital cellular technique is known to depart significantly from existing radio designs. Implementations will heavily exploit digital signal processing techniques to affect the necessary speech and channel error correction and detection coding as well as provide compensation for mobile radio channel multipath that exists in the real world. Radios will need to be dual mode, i.e. capable of both the AMPS and new digital format. RF, IF, and backend processing differences in both the receivers and transmitters will demand unique solutions that will burden subscriber units with some degree of circuit and function duplication needed to accommodate both systems. Simply stated, first generation digital equipment will not be of the same ilk as that is now available for AMPS.

The dual mode compatibility issue is key when dealing with a spectrum management situation as is the case for AMPS. The rapid deployment of subscriber units having the new, higher capacity, technology is crucial to achieving the desired capacity increase. Significant increases are only realized after a substantial fraction of the subscriber base are capable of the newer technology. The graph of Figure 1 illustrates this fact by showing the capacity advantage gained at a cell site where a new technology displaces single-user AMPS channels to provide 3 users. Dual mode capability is assumed, that is, overflow occurs from subscribers having the 3:1 technology to the AMPS channels, but not vice versa. The graph shows that a 2:1 overall system capacity improvement is realized only when over 70% of the subscriber base has been penetrated with higher capacity radios and 45% of the AMPS channels have been converted.

NAMPS

As the debate for an ultimate standard continues, there exists an immediate need for spectrum relief in some areas. No ultimate, fully validated digital solution is yet ready. Even if a validated specification was now in hand, no commercial subscriber equipment of the type, quantity needed to provide the necessary preload is close to commercial reality. This suggests the application of some bridging technology approach to meet the immediate capacity needs while maintaining the opportunity to transition to a future, ultimate digital solution.

Narrowband AMPS (NAMPS) is proposed in this paper to provide this necessary capacity relief while at the same time providing some desirable user and operator advantages. NAMPS is a digitally enhanced version of the proven AMPS standard. A unique combination of current analog voice processing and associated digital signaling, it allows tripling number of cellular channels in addition to providing performance enhancements and enhanced digital services.

NAMPS achieves its 3:1 channel increase over AMPS by splitting each AMPS 30 kHz. channel into three subbands and assigning each subband to a different user. Voice deviation is reduced to maintain a narrower channel bandwidth. Control channel signaling for NAMPS is the same as for conventional AMPS.

In addition to the spectrum splitting, NAMPS encompasses an additional differences. A continuous, high reliability, 200 bit/s signaling channel is added that is transparently communicated in an unused portion of the modulated spectrum below the speech spectrum. This channel serves to provide all necessary digital messaging for call processing, system control (power control, handoff, etc.), and supervision. This continuous data channel permits additional improvements, including the provision of enhanced data services and reporting of subscriber detected interference.

A summary comparison of some key radio specification differences between AMPS and NAMPS is provided in Figure 2.

User Perceived NAMPS Improvements

The digital subaudible signaling that NAMPS employs allows control information to pass between the base and subscriber continuously and is transparent to the user. In AMPS, conveyance of signaling information, (such as handover and power control commands) demands "stealing" the traffic channel momentarily from the conversation, which is often noticeable to the user as noise or muting.

The supervision of a conventional AMPS call hinges on the use of only 3 supervisory audio tones that are placed above the voice audio spectrum. With NAMPS, an expanded set of codes is provided by way of the subaudible signaling. This flexibility, in addition to the enhanced reliability of the protocol, reduces the likelihood of supervision detection errors in periods of low signal strength or interference. This ultimately results in improved call quality, fewer dropped calls, less susceptibility to anomalous propagation or frequency planning errors, etc. Message orders, including handoff commands, are verified with an ARQ protocol to provide positive confirmation.

Cellular system operation is notoriously nonreciprocal. For a particular call, the interference a mobile experiences can be quite different than the interference experienced by its serving base. With conventional AMPS, there is no provision permitting the subscriber to inform the network that interference or noise is detected. With NAMPS, the continuous subaudible signaling provides a mechanism affording this enhanced capability. For one, the downlink signaling itself furnishes the subscriber a convenient means for assessing the quality of the channel. Then, the reverse signaling channel provides transport to report this measured information to the base. This procedure is termed Mobile Reported Interference (MRI). The system can react to quality reports by performing some corrective action such as boosting the base station power to the subscriber or handing the call off to a different frequency or cell.

Quantitative performance improvements provided by MRI have been obtained by extensive computer simulation and field testing. Audio quality is related to the C/I ratio a subscriber experiences. For analog, audio becomes degraded when the C/I drops below 17 dB which can occur when systems are experiencing heavy utilization or the user wanders to noisy locations. Proper utilization of NAMPS MRI with corrective action by the network can reduce the time spent with degraded audio nearly five fold. Simulations further suggest that time spent below 10 dB C/I (often considered the "dropped call threshold") might be reduced even more. With MRI improvements, the NAMPS system audio quality will on the average be better than AMPS system audio quality.

With NAMPS, the required radio signal bandwidth is reduced and therefore less noise is associated with each user channel, that is, there is improved signal to noise performance in comparison to AMPS. This improved NAMPS radio sensitivity suggests greater range and deeper in-building penetration.

Operator Perceived NAMPS Improvements

NAMPS provides significant benefits to the cellular system operator. It is an economical, low risk, means of enhancing channel capacity up to three times that of AMPS. Upgrading an existing site avoids entirely the time consuming effort and expense associated with obtaining a new site. Since fewer sites are involved, maintenance costs are reduced and trunking efficiencies of backhaul trunks can be increased.

In many cases, an upgrade at a cell site might be very simple. It may only involve the installation of some new transceivers, scanning equipment, and software.

As cited above, the enhanced NAMPS performance will lead to a better grade of service to the customer. In particular, channels will be more readily available, the number of dropped calls will be reduced dramatically, audio quality will be improved, and coverage will be enhanced. The net result will be a happier customer and improved revenues.

Any capacity enhancement afforded the operator adds flexibility that would otherwise not exist. For example, the existence of "extra" channels permits the operator to reserve channels for special usage, including unique coverage solutions, "private" systems, etc.

Digitally Enhanced Services

The continuous, digital, full duplex, subaudible signaling channel that NAMPS exploits provides the operator a competitive advantage. Customers can be offered value added and revenue generating digital message supplementary services. For example, a short message service would allow the communication to a user of a brief digital message such as the calling party's number. Paging services can be provided, with acknowledgement. Dispatch operators might utilize the short message with predetermined inquiries and responses to communicate with their fleet. The user could also be provided continuous status indications, such as "voice mail waiting". "Group page" capability allows a dispatcher the ability to signal his entire fleet of users at once. All these enhancements are made possible through the use of the NAMPS signaling channel.

312

NAMPS Frequency Planning

The impact of NAMPS on frequency planning aspects has been exhaustively characterized. Despite the reduced deviation, it has been demonstrated that NAMPS operates with any of the typical frequency reuse patterns employed today with AMPS. Due to the stated operational improvements, NAMPS link quality will be generally better than conventional wideband channels. Frequency assignments are made with the rules similar to those used for current AMPS systems. All three NAMPS channels that occupy an AMPS channel are considered cochannel to only one AMPS channel. Furthermore, a single 10 kHz NAMPS guard channel is all that is necessary to protect an adjacent AMPS channel from NAMPS spectrum.

NAMPS as a Bridge to Digital

It is the inevitable future transition to an ultimate digital cellular solution within the allocated spectrum that makes the compelling argument for NAMPS. NAMPS can be immediately deployed with low cost subscriber radios that operate with either the conventional AMPS format or the higher capacity NAMPS format. Dual mode operation allows system controlled switching between the two formats in a way that is transparent to the user. This will allow the adequate time necessary to thoroughly "shake-out" the digital cellular approach.

As the subscriber base becomes penetrated with dual mode NAMPS radios, it is possible to reallocate cleared channels which are needed to implement evolving digital technology. In light of the enhanced capacity and performance afforded by NAMPS, the transition is accomplished in a nondisruptive manner while maintaining a high grade of service to all users.

NAMPS Deployment Status

A considerable amount of effort has already been invested in validating and field testing the NAMPS approach. Extensive simulations and laboratory bench testing have been conducted to support the specification's development. Performance improvements have been verified through the use of both internal and independent audio quality (mean opinion score - MOS) testing assessments.

With regard to actual field testing, by August of 1991, Centel Cellular and Motorola had already completed an evaluation using a portion of the Las Vegas cellular service area. Expansion of the number of converted sites is already planned for the near future.

The NAMPS concept is not an entirely new one. A similar split-channel technology, NTACS, is currently commercially deployed in Osaka, Japan. On a technical basis there is a striking similarity between NAMPS and NTACS, including the use of a continuous subaudible signaling channel. The essential difference is that NTACS is a 2:1 split of the existing Japan TACS system, which is based on 25 kHz. (vs AMPS' 30 kHz.) spaced channels. The NTACS system has been exhaustively tested in Osaka's nearly 100% portable challenging RF environment with nearly 100 % portable users. The NTACS standard enjoys subscriber unit sourcing from at least six manufacturers.

The ability to meet immediate customer expectations for low cost, size, and weight portables is also assured. As an extension of the existing AMPS system, it is possible to directly leverage the technology of existing analog portables, which have already advanced rapidly down aggressive product experience curves. This is evidenced by the recent announcement and significant shipments of Motorola's 7.7 ounce, NAMPS-compatible, MicroTAC Lite™.

The NAMPS specification is an open standard. Licenses for essential technology to implement the standard have been offered, royalty-free, to all subscriber and infrastructure equipment manufacturers. Already, some 27 licenses have already been requested.

Summary

NAMPS technology affords an immediate solution to effectively more than triple the capacity of cellular systems. It supports the requirement of providing a dual mode solution with portables that meet the user expectations regarding cost, size, weight and talk time. Besides capacity advantages, it affords a cost effective means to improve system quality and simultaneously provide new subscriber services. NAMPS is based on proven technology and provides a low risk, gracefully evolution path towards an ultimate digital cellular solution as it becomes available.

PERSONAL COMMUNICATIONS: POTENTIAL AND PITFALLS

John A. Gilbert,
Lapp-Hancock Associates Limited,
Ottawa, Canada

1. ABSTRACT

The promise of Personal Communications has the potential to change the shape of world-wide telecommunications over the next decade. Technologies driving these changes could benefit developing countries, enabling them to establish new infrastructures and employ low-cost terminals. Several issues must be addressed if the potential is to be realized. Failure to resolve these issues could delay the implementation of the full benefits of Personal Communications. If costs remain high, because of limited public adoption of these new services, developing countries may not be able to take advantage of the potential.

2. INTRODUCTION

Personal communications networks and services have the potential to bring dramatic changes to the provision and use of telecommunications. The magnitude of these changes has been compared to the impact that the personal computer had on society in the 1980s. The technologies which will bring about these changes also have the potential to bring low cost telecommunications to those parts of the world yet to fully participate in the communications age. The potential is real, but there are many issues to be addressed if that potential is to be realized.

3. THE VISION OF PERSONAL COMMUNICATIONS

The promise of personal communications is best captured in the vision:

"The ability to communicate with anyone, anywhere at anytime".

Variations of this vision can be found in many published predictions of evolving mobile services. However, the fine print often contains limitations on the vision which restricts its full potential. There may be restrictions on the availability of bandwidth, geographical constraints, limitations due to the cost of equipment or services or simply assumptions that other services will be in place to support the new services.

A combination of factors are critical to the further development of personal communications networks (PCNs). Examples of these factors are:

- the introduction of the powerful attributes of "intelligent" networks;
- the introduction of the "personal" number;
- significant reductions in the cost of mobile and fixed user terminals;
- the assignment of radio frequency spectrum.

A characteristic of personal communications which makes the service truly "personal" is the ability of the user to define services to fit his or her personal needs and requirements. Telecommunications services become personal in the same way as a computer is personal - users chose what they want the system to do for them.

At present two quite different forms of personal communications are converging. One, "untethered" or wireless/mobile communications, is the world of the cellular and cordless telephone and the wireless pager. The other, "tethered" communications, is the computer communications world. This is the result of yet another convergence, computers and communications, around virtually unlimited computer memory and the increasing availability of low cost communications bandwidth. An emerging, if ill defined, "buzz-word" in this world is "multimedia" communications. The two worlds

are quite different, yet to the user they could come together around at least three attributes.

3.1 PERSONALIZATION

The personalization of networks and services using the intelligence in the "intelligent network" through easy to use interfaces. The user defines the system parameters in a way analagous to setting the parameters of a personal computer. Simple examples could be instructions to the network to:

- direct all calls (from a user defined list of names) from your home to wherever you are travelling;
- provide exactly the right amount of bandwidth to send your real-time video transmission from Toronto to San Francisco at a specified time of day;

This "personalization" contains the key characteristic of personal communications - communications will be to a person rather than a place. The network will be capable of universally identifying individuals.

3.2 INDEPENDENCE OF PLACE

Independence of place implies the use of standardized (multimedia) terminals analogous to the conventional telephone set. After an initial orientation, the use of a terminal in someone else's office, car or on public transportation would require no training or special instructions. This will be particularly important if the growth of mobile use achieves predicted levels.

3.3 THE SEAMLESS CONNECTION

The "seamless" connection of people to people (or to information sources). The user should be able to assume that the connection between terminals, networks and people is virtually direct. In existing networks this can be taken for granted for voice, data and facsimile services. However, such apparently "seamless" connections are more likely the result of interconnecting agreements which may be masking the reality - that many systems are not compatible and seamlessness for wide band services may be difficult.

Theoretically the combination of global networks with these attributes would provide universal access and the possibility of participation by all - by customers in both the industrialized and the developing world.

4. AN OPPORTUNITY TO BRIDGE "THE MISSING LINK"

The enormous gap between telecommunications infrastructures and services in the industrialized and the developing worlds was highlighted in the 1985 report of The Maitland Commission, The Missing Link . The Commission was tasked with recommending " ...a range of methods including novel ones for stimulating telecommunications development in the developing world using appropriate and proven technologies" and provided a set of recommendations aimed at bringing significant improvements in telecommunications world-wide. Personal communications technologies, not even predicted in 1985, have the potential to add a new dimensions to the range of options suggested in the Maitland Report.

One can expect a range of new technologies to emerge as personal communications evolves, but already two elements in PCNs offer promise. The first is the possibility of low cost "mass production" terminals. The second is the millimeter-wave links that will be required, in at least early systems, to interconnect base transceiver systems to the base station controllers.

Combinations of these elements could provide a fast, cost effective method of providing basic telephone service - a cheap alternative to the installation of conventional telephone network infrastructures. A reduction of infrastructure costs could be of great importance to developing countries either as a temporary arrangement or as a way of "leapfrogging" over traditional approaches.

The feasibility of employing these methods is dependent on the cost of equipment, systems and software. An appropriate range of costs for terminals can likely be achieved if they become a mass market item. The millimeter wave links, controllers and base transceiver cellular systems costs will depend on the extent to which PCNs become established in the industrialized world.

4.0 CONSUMER ACCEPTANCE

In short, the availability of low cost equipment for the developing countries will be driven by mass consumer and business user acceptance of Personal Communications in the industrialized world. However, consumer acceptance in the industrialized world, although of course driven by cost, is likely to be affected by other considerations. Some of these are intangibles. Example of three of many areas that will need to be addressed are as follows:

4.1 THE PERSONAL NUMBER

The introduction of a personal number, unique to an individual and valid for life, coupled with the flexibility offered by the intelligent network, changes the relationship of people to communications services. For example, the receiving party, rather than the originator in a communications link will be able to control the communications. Most people would argue that this is necessary and desirable from the viewpoint of individual choice and personal privacy. However, new responsibilities will have to be defined and accepted by users. At one level, some entity has to asign the personal number - does this entity own the number, and if so, what are their obligations?

In a global system where a user has the power to instruct the network to forward calls to the other side of the world, what are the obligations of the user? If a third party calls my office in Canada, and the network connects the party to me, travelling in Australia, are the long distance charges my responsibility or his? These issues can be resolved, but the resolution may not be easy, nor readily accepted by users.

4.2 TOO MANY OPTIONS?

The plethora of options that could be made available to customers in the ultimate personal communications environment threatens to confuse all but the most sophisticated of user. The ability to personally define services involving different locations, media and other variables might well be a mixed blessing if the result is a consumer backlash. If easy access and easy to use terminals are to be a selling points for personal communications, there will need to be a structuring of features, perhaps aligned to lifestyle, price or other criteria.

4.3 TRANSPARENCY

Transparency between the tethered and untethered world may be a reality for voice and narrowband services, but that is not yet the case for wideband and multimedia services. Some wireless based "in-building" technologies (e.g. wireless LANs, cordless PABXs) will permit an in-building mobility more closely related to the tethered than the untethered world. This might well raise expectations, initially from the office or private telecommunications sector, that there should be an identical range of services in both the tethered and the untethered worlds. Unfortunately, the untethered user, dependent on the RF spectrum, is likely to be severely bandwidth constrained both by spectrum limitations and by the characteristics of radio based communications. Advances in compression technologies may help to overcome these disadvantages in part, but there will for some time be a disparity between the individual using the radic frequency spectrum and the individual who is using tethered communications.

These "public acceptance" factors will be relevant in the long term but in the immediate future technical and international standards questions are setting the pace for the introduction of the new personal services.

5.0 THE STATUS OF PCN

The technical characteristics of emerging Personal Communications Networks can be gleaned from published papers and from International Telecommunication Union (ITU) documents. The ITU papers in particular have stressed the need for internationally agreed standards, such as a common world-wide radio interface and frequency band. Among a host of issues to be addressed, spectrum, standards and access methods seem to be dictating the speed and form which the early personal communications networks will take.

5.1 SPECTRUM

The spectrum issues will be addressed at the forthcoming 1992 ITU World Administrative Radio Conference. Any changes in spectrum allocation approved internationally at the WARC will then need to be reflected in domestic allocations.

5.2 STANDARDS

While there has been some recent loss of momentum, the development of standards has moved ahead quite rapidly. In Europe, the approval by the European Telecommunications Standards Institute (ETSI) of the Digital Cellular System Standard (DCS1800) has provided a basis for the evolution of PCN in Europe. Several PCN trials are underway in North America.

5.3 ACCESS METHODS

Access methods continue to generate a lively discussion with, in the United States, a debate over Time Division Multiple Access (TDMA) and Code Division Multiple Access (CDMA) or spread spectrum.

5.4 MIGRATION TO DIGITAL

These developments are further complicated by concerns that there may be delays in migrating to the new digital services leading to Personal Communications because of the heavy embedded investment in analog systems. If delays are too long, other low cost alternatives, such as the public pay phone or pay fax, may further influence the rate of introduction of these services.

5.5 ACCEPTANCE IN DEVELOPING COUNTRIES

Developing countries have already demonstrated a willingness to adopt technologies to meet their needs through the use of existing mobile, cellular and satellite services. Personal communications promises to allow this trend to continue, but at considerably reduced cost and potentially greater impact.

6.0 MULTIMEDIA

Finally, on the tethered side, bandwidth, the limiting factor for multi-media applications is likely to become more readily available in the near future. Access to T1 or T3 capacities, or simply access to bandwidth on demand may soon be an option available to individual users, with appropriate tariffs to match. Bandwidth might soon be an opportunity, rather than a limitation.

7.0 SUMMARY

Each of these factors, among many others, will determine the evolution of personal communications, its public acceptance and ultimately its price. The developing world will be watching its evolution with some interest - if the price is right, these technologies might help to solve some long standing problems.

8.0 CONCLUSION

The potential of achieving the full potential of Personal Communications may not be fully realized unless global international standards and public acceptance are assured. Several "pitfalls" are evident which could prevent the benefits of Personal Communications being realized in the developing world. Factors which would bring about cost reductions need to be addressed if developing countries are to benefit from these new directions.

Standards and the Evolution of Wireless Services

James C. Hobbs
BellSouth Enterprises
Atlanta, Georgia, USA

ABSTRACT

Adherence to standards has been critical to the success of cellular in the United States and support of the GSM digital standard has greatly effected the speed at which this new technology is being implemented in Europe and the Pacific Rim. However, market confusion on digital cellular standards in the U. S. has created significant delay in digital developments for that country. Other countries, and wireless operators and manufacturers, should strive to minimize this kind of confusion when evolving their wireless and wired networks toward more advanced spectrum utilization technologies and service capabilities such as PCS.

1. Adherence to Standards

1.1 Analog success in the United States

The adherence to industry developed standards has been critical to the success of analog cellular in the United States. Analog cellular systems in Europe were independently developed and standardized in each country, while all U.S. cellular operators built to a single specification. The resulting economies of scale have led to greatly reduced terminal rates and an impressive growth rate. U.S. cellular subscribers have increased from less that 1 million in 1985 to 6.3 million cellular subscribers in early 1991. Over the same time period, European systems have only added 3.8 million customers.

1.2 Digital success in Europe

The European community has taken this problem into account in the standardization of its next generation -- or digital cellular systems. Adherence to the GSM standard for digital cellular has encouraged the relatively speedy development of this technology. There are now GSM systems operating in Germany and Finland and BellSouth is due to turn on a GSM system in Denmark in March, 1992.

The first standard setting meetings were held in Europe as early as December 1982 and by September of 1987 the first Memoradum of Understanding meetings were held. By starting early, and allowing for this 10 year planning period, the European community avoided the confusion of competing standards once the need for service became critical.

While GSM was originally touted for its pan-European capabilities, this may not be its most important charecteristic. Of more profound significance may be its effect on economies of scale for manufacturers which will lead to lower equipment prices and stimulation of demand.

1.3 Lack of Standard Support: U.S. Digital

Conversely, market confusion about digital cellular standards in the U.S. has contributed to significant delays in the availability of digital cellular equipment. In 1987, CTIA and TIA formed various committees to consider a digital standard for U.S. cellular. They had two major requirements: the technology must be deliverable by December 31, 1991 and it must be compatible with the existing AMPs technology. This compatibility issue is the major reason U.S. cellular could not use a GSM type digital system. After a heated debate among FDMA and TDMA technologies, the TIA formally endorsed TDMA as the industry standard in September of 1990.

A few months later, Qualcomm and PacTel announced that they were running tests on a spread spectrum technology called CDMA which they said could also make the specified date and would provide much greater capacity increases. This announcement came at a time when the industry was just realizing some of the difficulties associated with the reality of TDMA. The next year, when it became clear that CDMA would run at least 18 months later that the December 31, 1991 date, Motorola announced a narrow band AMPs technology that could be implemented quickly and easily. Though each of the air interface technologies being discussed in the U.S. -- TDMA, CDMA, and N-AMPs -- has its merits, BellSouth firmly supports the deployment of the agreed upon standard, TDMA.

Testing by one of our cellular operating concerns in Los Angeles and test data from Southwestern Bell indicate that the technology is sound, that voice quality is good and that capacity increases will initially be in the 3 to 4 times range. This does not imply that either CDMA or N-AMPs are not suitable alternatives in other markets or situations, and BellSouth is closely monitoring the CDMA testing in San Diego and the N-AMPs testing in Las Vegas. Either of the technologies might be the right decision in one of our markets outside of the U.S.

However, the Los Angeles and Southwestern Bell tests do support TDMA's qualifications as the standard for U.S. digital cellular. BellSouth hopes that more carriers and manufacturers can join its support of this standard in the U.S. and thus speed up the delivery dates and drive down the cost of TDMA dual-mode handsets.

To achieve a standard, an industry must put a stake in the ground and adopt a standard that will meet that goal. If one continues to move the stake for the standard forward, no one ever gets around to building and supporting the technology. In many ways, this is the best argument for the support of TDMA. GSM is not the most spectrally efficient standard imaginable, and TDMA may not be either, but they both supply adequate capacity increases. Cutting off the specualtion period and moving on to the implementation of these systems will allow service providers to begin the important business of supplying their customers.

In the U.S., and around the world, telecommunications providers must keep in mind that technology is transparent to the customer. But market growth depends on providing services that answer the customers needs. We need to all agree on standards so that carriers can get beyond technology and concentrate on developing and providing service.

2. Global Standards

Though BellSouth is a firm supporter of system standards within large geographic areas, and we see the merit in economies of scale of countries like Australia and New Zealand adopting the European GSM standard, we are not yet convinced that a single, global standard is a necessity. The "international roamer" market is a very small one and its size does not seem to justify the considerable expense needed to implement such a worldwide system. There is the possibility of a premium service of this sort, but the prospect is still very expensive and the process of getting agreement of the many regulatory and provider groups involved is incredibly complex. More over, technical advances may allow for multi-mode terminals for the small number of users that travel extensively.

3. The Standards Process

The standards process provides obvious benefits to both network operators and their customers; but it has drawbacks. BellSouth participates in a number of standard setting bodies including T1, CCIR, CCITT, WARC, CTIA and TIA. We are also a signator to GSM. It has been our experience that the length of the process and the complexity of integrating the requirements of disparate industry factions have a potential to slow or disrupt the process. One possible means of smoothing the process is to develop standards for systems that can be evolved to greater complexity overtime. However, it is important to remember that the second generation of a system -- such as a digital cellular systems being implemented where an analog system already exists -- must provide all of the services available on the existing system, plus new services, in order to meet customers expectations. This also allows the service provider to create product differentiation in order to sell new generation phones which are or might be more expensive.

4. Future Standards Needs

Many of what we today consider to be personal communications services will be provided over digital cellular networks. As we have discussed, the development of standards can greatly speed the deployment of these networks and enhance their interoperability.

Evolution toward "personal communication services" will focus additional attention on the standards issue. The wireless networks of the future must allow a wide variety of networks to interconnect in order to provide each customer with the services and functionality they desire wherever they might be. In-building systems must interconnect with public systems and many systems will need to connect to and take advantage of the intelligent network features of the wireline network. Institution of and adherence to standards will facilitate this sort of interconnecting and ubiquity of service.

INNOVATION, EDUCATION AND RESEARCH AT A DISTANCE: "THE SCIENCE OF HUMAN NUTRITION" (FOOD SCIENCE AND HUMAN NUTRITION 285)

DA Gans and HK Okimoto
University of Hawai'i
Honolulu, Hawai'i
U.S.A.

ABSTRACT

"The Science of Human Nutrition"/FSHN285 is a 3-credit introductory nutrition course, currently taught to over 300 students at the University of Hawai'i at Manoa (UHM) each semester. During the summers of 1990 and 1991, the class has also been successfully piloted as a Hawai'i Interactive Television System (HITS) offering to several remote sites as a two-way audio/two-way video course. Education and research have been combined in the two past HITS courses, in order both to define the student population served and to describe their nutrition knowledge and nutrition-related behaviors. In addition, the video tapes from the lectures can eventually be used as supplementary materials for similar courses being developed at several sites in the American Pacific.

1.0 INTRODUCTION

An essential function of the University of Hawai'i (UH) is to provide equal access to quality post-high school education to all qualified people in the state (1). However, the UH is unique among state land-grant institutions because of the geographic location of Hawai'i. The fact that we live on a group of islands in the middle of a vast body of water, the Pacific Ocean, creates special challenges and opportunities for those of us involved in addressing this mission of equal access to a college and university education for Hawai'i's people.

In this paper, we will describe an on-going collaborative effort between the Department of Food Sciences and Human Nutrition (FSHN) and the Office of Information Technology (OIT) both at UH-Manoa. Included in the discussion will be a description of "The Science of Human Nutrition"/FSHN 285 classes on interactive television, both past and proposed, and the major educational and research objectives associated with the course. In addition, we will describe future research plans for FSHN 285 on HITS and the use of the most current set of video tapes in other distance education courses.

2.0 HAWAI'I INTERACTIVE TELEVISION SYSTEM/HITS

HITS is a 4-channel inter-island closed circuit network in Hawai'i which has been designed as an electronic bridge for interactive telecommunication. Users of the system are defined as the University of Hawai'i, the Hawai'i State Department of Education and its public system, and other Hawai'i state agencies (2). At UH-Manoa, OIT maintains management and programming responsibilities for HITS for the total UH system.

An instructor using HITS can reach learners assembled at the same time in classroom sites throughout the state; and, through Cable TV, the instructor may even reach learners in their homes and at their work sites. In addition, video or telephone links from remote classrooms enable distance learners to interact with the instructor while the class is in progress or at other preset times. Because it connects all UH campuses, HITS is a powerful telecommunication tool which can help equalize opportunities in higher education for residents across the islands that comprise the state of Hawai'i.

3.0 "THE SCIENCE OF HUMAN NUTRITION"/FSHN 285

FSHN 285 is an undergraduate level, 3-credit course, which is listed as part of the UH-Manoa Natural Science core. The course attracts mostly students who are <u>not</u> majoring in food science or human nutrition; only about 10% of the students are currently enrolled as majors in the FSHN department. No college level science background is required; rather the course covers elementary aspects of the several biological sciences (e.g., biochemistry, anatomy, physiology) that are needed to understand the course content. Lastly, the enrollment in the course during the regular sessions has been increasing for the past two and a half years, by about 30-50 students per

semester. In fall 1989, about 140 students completed the course; this fall semester (1991), over 300 students were enrolled.

The content of FSHN 285 includes information about characteristics of nutrients and what they, and what the foods that contain them, do for humans. We also discuss how a healthy individual can choose an appropriate diet throughout the life span, and how humans and environmental factors can change foods and their nutrient content. In addition, we keep the information presented in the course as up-to-date as possible by including topics of current interest, such as a recent contest on the quality of water from various localities in the state, or continuing reports of Ciguatera toxicity in specific Hawai'ian reef fish.

4.0 PILOTING FSHN 285 ON HITS: SUMMER SESSION 1990

FSHN 285 has been offered on HITS as a course in both summer 1990 and summer 1991; it is scheduled to be offered on HITS again as a five-day-a-week, six-week summer session class in summer 1992. We identified four main objectives for our 1990 pilot offering. First, we wanted to compare the students attracted to the summer session course to those students who attend the class during the regular fall-spring sessions. Second, we needed to measure how successful we were in teaching the information. Third, we expected to use this pilot course to decide if it would be feasible to continue offering FSHN 285 on HITS. And, lastly, because we would have video tapes of the lecturer and of the students in the classroom, we planned to analyze the students' behaviors with respect to learning and learning styles and compare them across receive sites.

The experimental design was to have allowed a 2 x 2 analysis of variance of the data, because we were able to manipulate the mode of interaction between instructor and student and we had both on-island receive sites (UH-Manoa, live and remote studios; Leeward Community College) and off-island receive sites (UH-Hilo: Maui Community College). Unfortunately, because of insufficient registrants at two sites, we were unable to perform all the statistical analyses on the data that we had initially planned. We were able, however, to compare summer session students with the students who attended FSHN 285 during the regular sessions in 1990, using data from anonymous in-class questionnaires (return rate consistently 60-70%). The summer session students were older in years, were academically more advanced, and reported a wider variety of academic majors than did the regular session students. The majority (70%) of the students in all sessions were female, were not FSHN majors and were using the course to meet the UH-Manoa natural science core requirement. There was also a statistically significant trend across 1990: as the year progressed, the reported number of previous science courses completed before FSHN 285 decreased, perhaps indicative of the increase in enrollment of non-majors.

Information about nutrition-related habits was collected from all 1990 classes by means of an anonymous, voluntary questionnaire. There were no reported differences between spring, summer, and winter students with respect to current eating practices, eating episodes/day and eating styles. Most students reported that they knew they were eating a healthful diet, or that they wanted to now how to eat appropriately...both responses being indicative of a concern with adequacy or healthfulness of intake. In addition, the majority of the students stated that they ate 3-4 times a day and described their diet as "omnivorous."

Between 40-50% of all the students who completed the questionnaire reported that they were satisfied, within 5 lbs, with their current body weight; another 40-50% of the students wanted to lost at least 5 lbs; and the remaining 10% wanted to gain at least 5 lbs. Over 50% of the students never or seldom used vitamin/mineral supplements; the remainder were evenly divided between answers of "usually yes", "every day" and "only when not well." Similarly, reported alcohol usage did not differ between the three classes. The vast majority (over 80%) of the students reported seldom or never using alcohol. Most of the other students recorded 1-2 episodes of alcohol use each week. Finally, there are consistently about 20% of the students who report binge/purge behaviors, indicative of the eating disorder, bulimia. A few, about 6% of the respondents, reported engaging in these abusive behaviors as often as once each day.

Summer session students did differ from regular session students, in 1990, on two measures of dietary habits. More summer session students reported that they were, themselves, responsible for the majority of their food preparation when compared to the regular session student. In addition, the summer students relied more heavily on popular media than on friends or parents for nutrition information; the regular session students relied more heavily on friends and parents.

In order to determine the degree of success of the pilot class and to assess the feasibility of future FSHN 285 offerings on HITS, we examined the distribution of examination scores for

regular and summer session students. There were no significant differences among the examination scores or among the final grade distributions across 1990. Thus, we considered the HITS class to be as effective as the non-HITS classes for teaching the information in FSHN 285, and we agreed that the interactive TV class should continue to be offered the following summer. We were, however, unable to draw any conclusions regarding learning styles between receive sites, because as mentioned above, the distribution of students across sites made valid statistical analyses impossible.

5.0 RESEARCH CONTINUED: SUMMER SESSION 1991

Because of scheduling difficulties in summer 1991, FSHN 285 was taught as a four-day-a-week, six-week course through the College of Continuing Education and Community Service (CCECS). Five remote sites were included: UH/Hilo, Maui Community College, Leeward Community College/Oahu, Kapiolani Community College/Oahu, and Kauai Community College. This arrangement precluded using a balanced design of site and mode of delivery, as had been attempted the previous summer. Instead we took the opportunity to address a different set of research objectives. First, because CCECS requires all instructors to prepare a packet of information for the students, we were able to investigate the feasibility of using this delivery mode to distribute previously FAXed or mailed printed material for the FSHN 285 class. Second, because a non-HITS FSHN 285 was being taught the hour before the scheduled HITS class by the same instructor (DG), we were able to collect extensive data and later compare distance learners and in-class learners with respect to demographics, nutrition knowledge and nutrition-related behaviors. Furthermore, by including completion of the several questionnaires in the students "extra credit" points, we were able to collect information on individual students, rather than anonymously, as had been done previously.

Preliminary analyses of the data indicate that subtle differences exist between the total groups of students who took FSHN 285 in summer 1990 and summer 1991. For example, although there were no significant differences in age or gender distributions, the students of summer 1991 were less advanced academically and had taken fewer science courses than had the students of summer 1990. However, we have documented significant increases in nutrition knowledge in both HITS and non-HITS summer 1991 classes, as measured by a 30-question pre/post test. Current data analyses are focused on whether this knowledge change is a general one, or if certain nutrition topics are better learned than others. and if HITS or non-HITS delivery increases particular knowledge better. In addition, a 39-item eating behavior checklist, derived from the U.S. Dietary Guidelines (3), was administered to all summer 1991 FSHN 285 students. Thus, we will be able to investigate relationships between reported dietary behavior and nutrition knowledge. Furthermore, we will be able to relate these changes to appropriate demographic variables in both the HITS and non-HITS classes.

We have learned several important pieces of information from the Summer 1991 HITS class, despite the fact that enrollment in the televised class did not meet our initial expectations. First, we confirmed that it is feasible to collect a wide variety of data from a large number of students (n = 82) in a conventional classroom setting (n = 75) and from a smaller number (n = 8) in interactive television classroom settings, scattered across 5 remote sites. In addition, we discovered that using a pre-published packet of information was a less complicated and more reliable means of disseminating information to all students. It was especially more effective for the HITS students at remote sites. We have also documented that learning can be just as effective when the instructor has no students in the studio and must teach only to students at remote sites, as it is in a conventional classroom setting where the students have direct access to the instructor. Lastly, we have had the opportunity to experiment with developing supporting educational materials for presentation of identical nutrition information in two very different types of classroom setting.

6.0 THE FUTURE OF FSHN 285 ON HITS

We are planning to offer FSHN 285 again as a HITS class in Summer 1992. Our current proposal is to combine a large on-site class with several remote site classrooms, both on-O'ahu and off-O'ahu. We will continue to collect demographic information from all students, and will again administer pre- and post-tests of nutrition knowledge and food-related behaviors. In addition, we hope to create a balanced design to determine if learning is significantly effected by mode of delivery and/or mode of access to the instructor outside of regularly scheduled class time. Finally, we will be monitoring the students' classroom behaviors in order to correlate the behaviors with learning, as measured by scores on exams and assignments, as well as by reported change in dietary behaviors.

7.0 FSHN 285: BEYOND HITS

We have videotaped each lecture transmitted via HITS during the past two summers and plan to do the same for summer 1992. These videotapes have already served a number of purposes. Of course, they allow immediate feedback to the instructor with respect to correctness of lecture content and appropriateness of delivery. In addition, we now have access to a complete series of FSHN 285 lectures which we plan to update at least once each year.

Several of the FSHN 285 videos have been copied and distributed to individuals or institutions interested in the possibilities of televised interactive classroom programming. In particular, one of us (DG) is involved in an articulation process, financed in part by funds from the Agricultural Development in the American Pacific (ADAP) Project. We are currently discussing plans to develop four courses at Northern Marianas College (NMC), a community college on Saipan, CNMI, similar to courses already being taught in the FSHN department at UH-Manoa. Five of the 1990 tapes were delivered to NMC to demonstrate the technology, because the college is interested in developing an interactive television system on Saipan. Furthermore, the complete set of 1992 tapes will be later made available to the instructor at NMC who will be teaching the FSHN 285 class there. These tapes will help the instructor update her nutrition knowledge. The most recent set of tapes may eventually be used each year as supplementary material for the students at NMC when the class is being taught there.

8.0 FUTURE RESEARCH CONCERNS AND QUESTIONS

We have identified one problem that we must address more aggressively: we have had limited success in attracting large numbers of students to the FSHN 285/HITS class at the remote sites (n = 7, 1990; n = 8, 1991). Thus, we need to try new strategies for publicizing the class and for identifying if larger audiences exist and how to reach them. We believe that offering the class as a CCECS course is one solution, because one of the implicit goals of CCECS is outreach to those students who have been traditionally underserved by higher education (4). We also have begun identifying special target audiences, such as secondary health education, home economics, and science teachers, who may be interested in making their knowledge of human nutrition as current as possible (5).

The primary goal of any research that we conduct with the FSHN 285/HITS classes is to identify the combinations of informational content, delivery, and supporting materials and services that produce the most effective learning environments for the students, especially at the remote sites. In order to achieve this goal, we will continue to explore the limits of HITS in Hawai'i and to investigate appropriate and innovative uses of the televised videos throughout the American Pacific.

Instructional Telecommunications In Alaska: Ten Years Later

Barry Willis, Director
Statewide Distance Education
University of Alaska System
Anchorage, Alaska USA

ABSTRACT

In the past 10 years, Alaska has been heavily involved in the planning and implementation of instructional telecommunication systems. Early efforts focused on developing technical infrastructure and ended abruptly in the mid-1980's with the drop in the price of oil and resulting budget reductions. While the mid/late 1980's focused on re-thinking the technical assumptions leading to early instructional system implementation, current efforts focus on more complete needs assessment prior to technical decision making.

In 1981, a focus of the PTC Conference was entitled "The Alaska Case Study" (1). The intent of the case study was to highlight the trials and tribulations that a State (by analogy, a small Country) might face when accelerating telecommunication development in a multi-cultural, climatically harsh, and sparsely populated setting.

In Alaska, 1981 was a time of great hope, anticipation, and expectation. By any standard, the state was well off with abundant oil wealth providing 85 percent of the state's income and contributing billions to its treasury. A few years earlier, Alaska had chosen to use some of its anticipated oil wealth to extend educational opportunity to all corners of the state using a sophisticated telecommunication delivery system. In the enthusiasm of the moment, however, and despite the protestations of those urging caution and planning, a series of decisions were made emphasizing equipment acquisition at the expense of a thoughtful and thorough needs assessment. The result was a technological "solution" in search of an instructional "problem," setting the stage for a 10 year cycle of expectation, frustration, and regeneration.

BACKGROUND

In the early 1970's, Alaska entered a period of experimentation utilizing the Applied Technology Satellite (ATS) system (2). The ATS-1 experiment in educational broadcasting began in 1971 with the delivery of audio and data transmission to 26 communities throughout the state. The system, using three and four meter earth stations, proved successful despite the failure of the delivery system's video capability. In fact some believe that the failure of the video component was beneficial because it encouraged users to explore the instructional uses of audio (2).

In 1975, the ATS-6 experiment began and focused on the distance delivery of video programming to 16 communities and proved that video could be delivered through small earth stations at high latitudes from a satellite in geostationary orbit.

This was Alaska's introduction to instructional television and raised rural Alaska expectations to the point that the Legislature appropriated funds for a rural television demonstration project (TVDP) in 1976. This demonstration continued through 1980 as a mix of educational services during the day and network television in the evening.

The University of Alaska's (UA) formal

involvement in instructional telecommunication for distance delivery began in February of 1979 with the establishment of a committee, charged with assessing needs and exploring distance delivery options (3). It is both interesting and ironic, however, that early in this planning document, it is evident that the decision had already been made to use satellite-based television as the primary delivery system, with audio conferencing intended to complement and provide an interactive system component. The remainder of the report dealt with management and implementation issues.

The focus on "solutions" not "problems," typified the early efforts of educational administrators in Alaska throughout the late 1970's and early 1980's and culminated in the creation of the Learn/Alaska Network (LAN), a joint UA and Department of Education (DOE) enterprise.

The LAN statewide instructional television/audio system appeared to work quite well for the first two years, although by 1983 questions started to arise concerning the instructional effectiveness of the system. Rather than slow system development and evaluate the instructional progress to date, however, all effort was put into continued system development and strengthening the technical infrastructure.

DECLINING REVENUE

By 1985 it had become increasingly apparent that the state's oil wealth was diminishing due to a decrease in the per barrel price of oil. Declining revenues resulted in close scrutiny of all state-sponsored programs, including the LAN instructional telecommunication network. Within the university alone, for example, impending budget cuts necessitated a 30 percent cut in the UA systemwide budget in the course of one fiscal year. As a result of intense scrutiny, legislative, administrative, and faculty support for the instructional telecommunication system declined. Not surprisingly, internal budget cutting resulted in various proposals for downsizing the instructional telecommunication system. This review process continued until June 1987 at which time it was announced that the LAN was being dismantled. Oversight of a vastly reduced television delivery component was reassigned to one branch of the university while an expanded audio conferencing capability was shifted to another university unit. The DOE became a system user, relinquishing management oversight.

In terms of instructional telecommunication, late 1987 through 1988 was a time of reassessment with educational administrators, legislators, and involved faculty...not to mention students, left scratching their heads, wondering what had become of a system that had appeared, at one time, to be so promising.

In retrospect, some would suggest this period of confusion, frustration, and question, not to mention the absence of technological funding, was the best thing that ever happened to instructional telecommunication in Alaska and led to an evolution in the way educational administrators view technological decision making.

Although the system budget was dramatically reduced in 1987, much equipment and infrastructure remained. More importantly, those involved in the early development of the system, as well as those watching from the sidelines, matured in their thinking as to how an instructional telecommunication system should develop. While talk of planning had always been popular, it was not until the LAN experiment concluded that administrators and faculty alike, understood that effective needs assessment planning took more than talk. It required focused action.

By the late 1980's each major UA unit had developed a distance education capability established to identify and meet the specific needs of the educational constituencies they were charged to serve. Rather than falsely assume one system could meet the needs of all learners, different approaches were used focusing on identifying specific learner needs, multi-cultural characteristics, and educational goals. These efforts resulted in various approaches to instructional

telecommunication delivery and focused on the concomitant provision of support services as instructional telecommunication systems were tested and implemented.

While, the urban center's of Anchorage, Fairbanks, and Juneau found, for example, that instructional television programming, relying on pre-packaged telecourses, could be quite effective, the rural campuses sought more individualized approaches to instruction focusing on interactive technology such as audio and computer conferencing.

At the same time, it became evident that the "rural" learner in one village might have totally different educational needs and desires from an equally rural learner living several miles away. As such, more emphasis was placed on needs assessments, village-based facilitation, and on-site visits by faculty. Increased face-to-face interaction encouraged educators to experience, first hand, the needs and realities of village life, as opposed to long distance assessments based on secondary information and questionable assumptions.

AT PRESENT...

During Spring 1991 alone, the UA offered over 190 different distance delivered courses throughout Alaska. Interactive television, for example, combining one-way video and two-way audio is being used to deliver a graduate level Masters of Public Administration curriculum to military sites statewide. The same system, relying on satellite delivery, is used to provide instruction to more traditional learners, as well as Alaska's prison system.

Initiated by the University of Alaska Anchorage and the University of Alaska Southeast, the "LiveNet" system relies heavily on cooperative programming and technical support as well as very competitive transponder rates (i.e. $100 per hour) through a local commercial carrier. In addition to the public administration curriculum, courses in education, history, geometry, literature and Native issues are being delivered to specific sites statewide.

Pre-packaged telecourses, especially popular in Alaska's more urban areas since the late 70's, continue to fill an important niche, when supported by interactive audio conferencing, facsimile, and strong print components. The University of Alaska Anchorage, for example, often delivers over 20 telecourses per semester to students throughout southcentral Alaska.

Audio conferencing remains a pivotal component of Alaska's distance education efforts. With over 250 established audio sites statewide and relying on central, regional, and remotely controlled audio bridging facilities in Anchorage, Fairbanks, Juneau, Bethel, Nome, and Kotzebue, the University of Alaska Fairbanks, alone, offers over 80 courses per semester to over 100 sites. As with "LiveNet," many of these courses use an integrated delivery approach incorporating print, facsimile, and electronic mail.

INCREASING INTERACTION

The importance of "student-student" interaction remains a critical distance delivery component. To cost effectively link class participants in 265 communities spread over 1,530,700 sq. km., an extensive electronic mail system is in place and centrally managed. And to ensure student participation, regardless of local facilities, both the UA and DOE distribute "lap top" computers with internal modems to students participating in specially designated courses.

While a major benefit of audio conferencing has long been its ease of use, relative cost effectiveness, interactive capabilities, and inherent spontaneity, a major disadvantage has been the lack of an interactive visual component to promote "teacher-student" and "student-student" manipulation of graphic images. This limitation has been especially evident in math, science, and laboratory courses. To fill this "visual gap," various experiments and pilot studies are underway utilizing different multipoint-to-multipoint interactive digital graphics (IDG) technologies such as Optel, Scanaware, and Bell Canada.

A costly disadvantage of past voice/data distribution systems in Alaska has been the need to incorporate two lines per site, one each for audio and data delivery. Recently, however, the University's computer network, through its "Alaska Telegraphics Project," has developed a single-line solution in which the IDG data stream "piggy backs" on the same phone line used for audio conferencing. This is especially significant given the patchwork of phone systems linking Alaskan communities.

Additional attention is being placed on long term distance education planning in the university as it moves towards systemwide course delivery. Towards this end, a statewide study was recently conducted to identify, prioritize, and provide alternative methods for dealing with the myriad policy and procedural issues arising from systemwide course delivery. This project, nearing completion, will be used by the university's chief academic officers to set direction and ensure that the distance delivery resources of the university are marshalled to meet specific academic needs.

Alaska's university system is not alone in its emphasis on distance education. The DOE is an active member of the grant sponsored Pacific Northwest Star School Partnership and is working with 35 school districts in Alaska in the installation and use of satellite delivered educational programs and services. By spring of 1992, 81 school sites will be equipped with the satellite and data receive equipment funded through the grant and will be utilizing the services and courses it has made possible. An additional 32 sites, investing in satellite systems prior to the grant, will make a total of 113 Alaska schools with satellite receive capabilities.

In addition, the DOE continues to produce live interactive video programs relying on satellite delivery to bring experts to students statewide. This same network is used by the DOE for overnight tapefeeds of instructional video materials.

Both the DOE and university system have found that faculty development and inservice training are critical to the long-term effectiveness of distance education efforts. Towards this end, various mentoring networks, workshops, and support services are in place to ensure that the distance delivery of instruction remains an effective and viable educational tool throughout Alaska.

SUMMARY

During the early 1980's the development of instructional telecommunication in Alaska was characterized by an emphasis on developing technical infrastructure and purchasing hardware. In contrast, the mid/late 1980's focused on review, retrenchment, and questioning of the foundational elements leading to the original technological assumptions. The late 1980's through 1991 have focused on identifying needs, establishing goals, and operationalizing the premise that instructional telecommunication requires a detailed understanding of the academic needs the technical system is designed to meet...prior to development and implementation.

Abstract

Facing a declining rural population and a concurrent reduction in schools serving rural students, Saskatchewan explores curriculum augmentation using telecommunications delivery strategies in secondary schools. A pilot project is described which tests a teacher-directed classroom production model and point-to-multipoint satellite delivery of secondary courses from three originating classrooms to widely dispersed receive schools. The pilot has exposed front-line educators to the logistical and pedagogical implications of this particular method of distance delivery to secondary schools.

Introduction

"Rural Saskatchewan is mourning the disappearance of schools from villages and hamlets everywhere, says Bob Thompson, head of the province's trustees association. When the school closes it is almost like the final nail in the coffin for many communities" Marud (1991)

Closure of rural schools is only one of the many problems that plague Saskatchewan's rural communities. Dropping commodity and livestock prices coupled with rising costs in every other sector have soured the rural economy for all but the mega-farmers. A declining, aging rural population stands a lonely vigil as the young leave the family farms for the city to seek a stable income and a school for their children. The local school, curling rink, equipment dealer, and grocery store constitute the final bastion of service to the young farmer, and when the school goes so does the support structure and interest in the local community. For a decade now farm children have faced a half to a full hour bus ride to the nearest local school in order to maintain a classroom population capable of supporting a reasonable breadth of curriculum. Now these more or less centralized schools are disappearing and with them the rural town infrastructure. This phenomenon is not unique to Saskatchewan, but is characteristic of schools in the rest of rural Canada and the United States.

More than 50 rural Saskatchewan schools have closed in the past five years and now more than half of the province's 200,000 students attend urban schools. Yet this has been one of the better half-decades considering that in 1940 Saskatchewan had 5,000 schools. These numbers dwindled rapidly throughout the next 50 years. In 1950, 4,000 schools remained, declining to 2,000 in 1960, 1,008 in 1970, 927 in 1980, and 850 in 1990.

Educators, business, and the public are engaged in a life or death search for a solution to overcome the huge education and training problems facing all sectors of society. In many of the strategic plans developing in North America and elsewhere, hope is pinned on a technological situation. Rapid advance in technology has catapulted us from the industrial age to the information age in two generations, resulting in technology based systems replacing existing systems in all aspects of life outside the school. The education system, particularly the K-12 system, is one of the last institutions to succumb to technology. Strategists are staking their reputations on articulation of technological systems to be not only the cause but also the solution to the educational ills facing us.

Nowhere is the potential greater for a technological solution than in rural areas of Saskatchewan and other remote jurisdictions characterized by sparsity of population and great geographic distances. New and emerging

communications technologies have the capacity to support new modes of learning in rural as well as urban settings. Technologies of communication and learning are converging in what has been described as "digital fusion" resulting in powerful interactive multimedia learning systems that are not "place bound" as are the traditional institutions of learning. It is now apparent that a learner can receive just as effective an education in remote areas as is possible in an urban area. The people of Saskatchewan have a long tradition of providing education where it is needed. The pilot projects described in this paper provide an overview of a strategy for revitalizing the curricula for schools in rural areas.

Saskatchewan

One of ten provinces of Canada, Saskatchewan is situated between Manitoba on the east and Alberta on the west, Northwest Territories on the north and the United States on the south. Figure 1 shows Saskatchewan as it is located on the North American continent. It is an interior province sharing with Alberta the distinction of having no boundary adjoining salt water. Saskatchewan has a population of 1,000, 000 (1990) and a geographical area of 652,000 sq. km. (252, 000 sq. mi.) including 178,000 sq. km. forested land and 81,631 sq. km. of inland water. Population density is about 1.5 per sq. km. (4 per sq. mi.) and is concentrated in the southern third of the province. Climate is continental, with cold winters and hot summers. The topography ranges from semi-arid rolling plains in the south, through the central grasslands (grain belt), to rugged Canadian Shield rock, swamp and forest in the northern half of the province. Agriculture is the largest single industry with farm receipts making up $4.1 billion (1986) of a $17.4 billion (1986) g oss domestic product. Other principal industries include manufacturing, mining, meat processing, petroleum refining, fishing, forestry and electricity production.

Elementary and secondary education in Saskatchewan is carried out by a system of Protestant and Roman Catholic schools. In 1989, 863 elementary and secondary schools served 203.866 students. Post-secondary institutions include seven regional community colleges with a non-credit enrollment of 86,000 students and two universities located in the largest cities, Saskatoon and Regina, serving 20,000 students. Four technical institutes in four separate locations across the province have 7,500 full-time and 21,000 part-time students.

On the Fringe - Distance Education at the Secondary Level

Once relegated to evening hours at the kitchen table, distance education at the secondary level is poised on the brink of a quiet revolution. No longer the poor cousin at the face-to-face instructional banquet, distance education is venturing out of the shadows and into the limelight.

Distance education is not new to the secondary scene. The Saskatchewan Government Correspondence School has been in operation for over sixty years, serving up high school credits to a diverse audience of shut-ins, adult high school completers, and students in school. Over 6,000 clients a year currently access an extensive inventory of print-based, independent learning packages. What is new to distance education is the proliferation of alternative delivery systems and the multi-sensory dynamics and enhanced teacher-pupil interaction that telecommunications technologies bring to traditional correspondence study. Concurrently, there is a perceptible change in attitude among educators, motivated by a complex set of economic and demographic circumstances, toward the integration of distance education methodologies into mainstream classroom practice. The realities confronting rural school administrators today have provoked thoughtful consideration of instructional technologies to help meet the needs of their students.

Figure 1
Saskatchewan is a prairie province located in the central part of North America

For many, however, investigating the potential of distance education is like travelling in foreign territory. Obstacles of varying shapes and sizes are strewn in the path of the educator newly exploring the terrain and a tantalizing array of technological innovations transforms the landscape. As Connick (1991) suggests:

> Technology fundamentally changes the concept and possibilities of access, quality

> and productivity because it reduces or eliminates traditional barriers of time, distance, cost, limited instructional space, limited instructional and support personnel, limited learning options, differing learning styles and pace, [and] unequal student preparation. (p. 2)

A thought-provoking notion, yet perplexing in its very appeal. The question confronting educators and administrators today is just how--by what mode of transportation--does a small, rural high school increase access to a broader range of resources and cross the barriers of time, distance, and cost? From itinerant classroom teacher to politician and policy maker, the need to forge new partnerships and develop alternative strategies for the equitable distribution of educational resources challenges the boundaries drawn by geographic location and tradition. As Connick stated:

> Dealing with fundamental shifts in educational power and allocation of resources threatens the traditional and comfortable. (p. 3)

No one technology; no one mode of delivery is a panacea. Volkswagons, Cadillacs, and Jeeps travel our highways achieving the same fundamental purpose, albeit in a myriad of designs appropriate to the driver's needs and budget. Distance education offers a similar proliferation of vehicles, from computer-assisted instruction, to audio and video teleconferencing, audiographics, electronic bulletin boards, and more. The technology exists. Barker, Frisbie, and Patrick (1989) conclude:

> The desired end result in distance education has been to provide an educational opportunity equal to that provided in traditional classroom teaching. A major factor in the growing interest in distance education is the ability to conduct live, real-time instruction between teacher and student(s) made possible by technology. This ability to simulate, as close as possible, a traditional classroom teaching/learning experience permitting live teacher/student exchanges and student/student exchanges--irrespective of geographical distance--is changing the scope and definition of distance education. (p. 22)

The authors suggest that the significant advantage of what they call "telecommunicated distance education" is the capacity to electronically bridge the geographic distance between small groups of students. They continue:

> Telecommunicated distance education projects are not focused on an individualized instructional model as is the case with correspondence-based distance education. Instead, the focus is on small groups or clusters of students at different locations networked together for real-time audio interaction with the instructor and with each other...The prospect of student-to-student exchanges not only increases the likelihood of socialization between students but also fosters the potential for peer tutoring and small group study. (p. 24)

Distance education in many high schools is still reserved for the kitchen table or, at best, a fortuitous gap in a student's time table. The student, ill-equipped for independent study and isolated in the experience, is in danger of becoming yet another statistic in the ranks of attrition. Communities cling tenaciously to tradition: a teacher planted firmly in front of a classroom of students, dispensing knowledge. Reality echoes with the footsteps of too few students to support the system. Teachers, threatened by technology, retrench and resist. Administrators struggle to maintain the status quo.

Despite the obstacles, the quiet revolution has begun. While the collective vision and the monetary muscle to move distance education from the isolated fringe to mainstream education has not yet fully emerged, the early adopters of change are at work.

> It is time to build the virtual classroom that provides the familiar interactivity between the learners and their teachers but without the constraints of physical reality. Distance education will bring knowledge to the learner, wherever he or she may be, whenever he or she can engage it. Technology will provide the means; innovative, proactive educators will provide the impetus. (Lever, 1991, p. 15)

Setting the Stage for Mainstream Distance Education

Saskatchewan has its innovative, proactive educators who are hungry for the knowledge, tools, and experience with which to operationalize the principles of distance education. The post-secondary sector in the province has, over the past decade, delved extensively into the ways and means of utilizing telecommunications technologies to reach beyond institutional walls. The University of Saskatchewan led the way during the early 1980's with trials in satellite-assisted delivery of credit courses. Early experiments spawned the formation of the Saskatchewan Tele-learning Association (STELLA), a consortium of institutions banding together to increase access to learning opportunities for place-bound learners. STELLA and its pioneering programmers forged the way for the implementation of a full-scale provincial satellite and fibre optic network known as the Saskatchewan Communications Network (SCN).

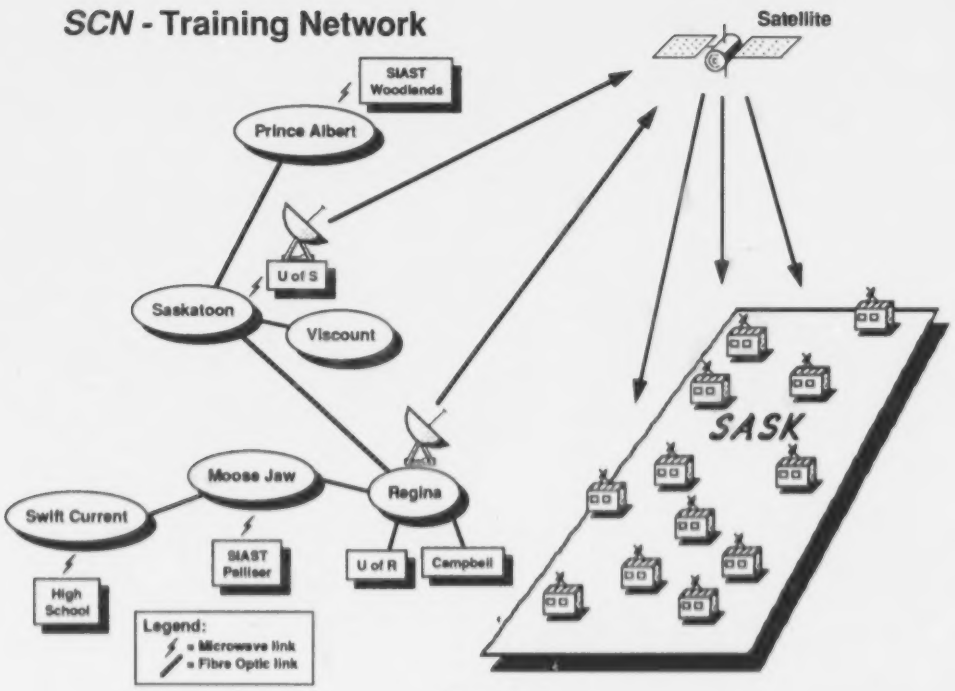

Figure 2

Saskatchewan Communications Network (SCN) provincial training network configuration

The evolution of SCN and its forerunner, STELLA, is described in the following papers: Brown, 1990a, and Brown, 1990b.

SCN comprises two distinct networks: the SCN Cable Network, an educational television channel distributed to cable subscribers, and the SCN Training Network, a narrowcast network dedicated to distance education and training. The Training Network's primary mode of delivery is a one-way video and two-way audio configuration. In cooperation with the province's Regional Colleges and post-secondary institutions, the Training Network transmits credit courses to 54 centres across the province. See Figure 2. During the 1990-91 academic year, 1,100 hours of instruction were delivered to almost 2,000 students. Network volume and student access continues to grow.

Telecommunicated Distance Education Enters the Secondary Arena

Experimental activities are beginning to percolate within the secondary sector. The innovators are acquiring a knowledge base through hands-on experience. Educators are critically assessing the pedagogical practices and instructional strategies that must shape and direct technical interventions. In 1989, the Eastend School Division began to gain recognition for an imaginative and aggressive approach to equitable access to resources. Outfitted with satellite receive hardware, the division's four high schools participated in early trials of "video on demand" technology, the precursor to Super-Man, the Switched Urban Programming for Educational Resources - Metropolitan Area Network project launched by Graham Bradley, Director of Research and Development, Saskatchewan Telecommunications. For a full description of the "forward and store" information delivery concept of Super-Man technology, see Brown and Oliver, 1990.

The second project that the Eastend School Division initiated was a small group, individualized distance learning project managed by facilitating teachers working in close collaboration with subject matter experts from the Correspondence School. The model shows promise. The team teaching approach bodes well for student success. Managing the group process and each student's progress requires a unique set of classroom management skills. Of equal importance is the investiture of independent study skills in students unaccustomed to managing their own learning. Gary Luke, Director of Eastend School Division, writes:

> We were not long in developing a policy of roles, expectations and structures to be employed in distance learning classrooms in the Eastend School Division. We have adopted a team teaching approach. The teacher in the classroom is responsible for the student's success. The teacher in the

classroom is teamed with other teachers miles away who have expertise in the subject areas chosen by students. There is a definite structure; a time when assignments are turned in as in a regular classroom; a time for instruction, although over the phone; a time for group discussion, a time to formulate questions; and regular quizzes and tests, as in a regular classroom. The only difference is that there are more people with expertise available to the student and a variety of subjects are being handled in the same class period--and the students are becoming somewhat technologically literate. (excerpt from personal speaking notes)

While students strengthen independent learning abilities and maintain group affiliation needs, the telephone and facsimile provide the vital link with experts at a distance. The facilitating teacher contextualizes and directs pedagogical practice. Luke concludes that the team teaching approach to "small groups of similar abilities" has been a successful method of implementing and enhancing distance education practice.

The Eston-Elrose School Division is experimenting with another mode of delivery: two-way video and audio using compressed video technology to link teachers and students in two high schools within the school division. Each classroom is outfitted with a television camera, microphones, and a key pad device which controls camera movement. A teacher located in Kyle teaches Geometry/Trigonometry to a class in Elrose and a reciprocal course in Calculus originates from Elrose. One of the primary objectives of the point-to-point delivery mode is to facilitate the efficient distribution of teaching expertise within the school unit, utilizing human resources among the four high schools to accommodate small group needs through distance learning. The project is in its first semester of operation and, according to school administrators, shows promise in fulfilling long-term teacher resourcing goals.

The balance of this paper will discuss a major pilot project that was launched by the Saskatchewan Communications Network and the Saskatchewan Government Correspondence School during the 1990-91 school year. It was a pilot that would test a teacher-directed classroom production model and point-to-multipoint satellite delivery of secondary courses from three originating classrooms to widely dispersed receive schools.

Interactive Televised Instruction - A Pilot Project

Denise, a Grade Eleven Algebra student, is stuck on an equation. She's asked her teacher, Mr. McLeod, for help. "Let me have a look at your assignment, Denise." He's able to spot her problem immediately and show her where she's gone wrong. A few minutes later, he discusses the same problem with the entire class.

This scene takes place daily in schools across the country; the difference with this one is that Denise and Mr. McLeod are over 300 kilometres apart. They discussed the problem by telephone and Denise's assignment travelled back and forth between their facsimile machines. When Mr. McLeod presented the problem to the class, some of his students were seated in front of him while the rest of his class watched him on their television monitors. Telecommunications technology brought them all together.

The pilot project was designed to transmit live, interactive instruction via satellite using a one-way video, two-way audio system configuration. During the first semester of the pilot, courses originated from production classrooms at Campbell Collegiate in Regina, Swift Current Comprehensive High School in Swift Current, and Viscount Central School in Viscount. Classes were transmitted via satellite to schools in La Loche, Sandy Bay, Plenty, Oungre, Rabbit Lake, Burstall, Bateman, and Kinistino. The distance from Oungre in the south of the province to the predominantly native community of LaLoche in the north is approximately 850 kilometres or 528 miles--Oungre is situated just north of the 49th parallel and LaLoche at the 57th parallel--a distance representing not only geographic separation but diverse cultural and regional differences as well.

Instructional Configuration

The Correspondence School affixed the acronym ITI to the project--Interactive Televised Instruction--intended to reflect not only the principal mode of delivery but the capacity for real-time, teacher-pupil interaction. With funding assistance from SCN, the Correspondence School undertook the complex task of managing the instructional components of the project. A comprehensive set of objectives was outlined, including the following:

- reinforce, explain, illustrate, and expand upon print materials
- develop a teaching tool to disseminate information, elicit action or reaction, and utilize critical and creative thinking and problem solving skills
- accommodate a wider variety of learning styles (visual and auditory)
- promote interactive and resource-based learning by providing motivation, background information and direction for follow-up activities
- consciously incorporate instructional strategies that would promote development of common essential learnings and gender equity
- accommodate large groups at a few different places, or small groups, even

individuals, at various sites throughout the province
* improve cross-cultural understanding and appreciation
* increase student appreciation of technology as a medium for learning
* foster the image of the Correspondence School as an up-to-date, viable, learning institution. (Eger, 1990)

The Correspondence School solicited applications from potential receive schools. In order to participate in the pilot, schools were required to install the appropriate hardware to receive the signal, incorporate Correspondence School policy guidelines, provide a facilitating teacher, attend planning sessions, and pay tuition fees on behalf of their students. In addition to coordinating the receive schools, the Correspondence School, in consultation with the production schools and receive sites, selected the courses for delivery, provided instructional design and team teaching support, set and marked exams, and conducted formative and summative evaluations of the pilot.

Three courses were chosen for first semester delivery: Algebra, French, and Accounting. Geometry/Trigonometry, French, and Biology were chosen for the second semester. In each course, the production school's tele-teacher taught his or her own on-site class in conjunction with live, interactive sessions with remote classes. Students at a distance viewed the teacher on a television monitor and could call in by telephone to ask questions and respond to the teacher. Homework problems, assignments, and quizzes travelled between the teacher and students by facsimile machine. The facilitating teacher at each receive site managed the group process and guided students in their studies, as well as maintained the instructional liaisons with the tele-teacher and Correspondence School support staff. The Correspondence School's independent study packages provided the curriculum and print support.

Technical Configuration

The delivery system required the establishment of a one-way video, two-way audio teleconferencing and facsimile network originating from the three production classrooms in Swift Current, Viscount, and Regina. Each classroom was equipped with a portable studio production kit enabling teachers to deliver live, interactive instruction to receiving schools. The production kit, designed by Jim Sax of Video One Systems Ltd in Saskatoon, contained three single-chip cameras, a six-video input switcher, a three-channel wireless receiver with three high band VHF wireless microphones, a standard industrial video cassette recorder, a frame synchronizing time base corrector with standard broadcast video level output, and an 11" colour monitor. The hardware configuration was built into a custom-designed aluminum shell casing.

The hardware configuration was designed to be teacher operated. A general objective of the pilot was to test the feasibility of a low-end production system--a system requiring minimal cost and production expertise and a minimum of obtrusive hardware and personnel. Randy McLeod, tele-teacher from Campbell Collegiate, assisted by Dave Zimmer of Saskatchewan Telecommunications' Research and Development department, began to explore ways of improving the hardware configuration. The most innovative enhancement was the addition of a remote controlled, infra-red switcher which replaced the original push-button switcher. This enabled the teacher to remote control camera selection from anywhere in the classroom, negating the need to rely on an assistant or to return physically to the control panel each time a different camera shot was required. An Elmo Visual Presenter was a further important addition to the configuration to improve graphics and overhead transparency transmission, as well as display student assignments and working diagrams. Other enhancements included a second display monitor, an additional video cassette recorder to enable both record and play-back, and a fourth camera.

A combination of fibre optic and microwave links were established to transmit signals from the production classrooms to satellite uplinks in Regina and Saskatoon. SCN offered school boards affordable hardware lease option packages to outfit individual receive sites with Ku-band satellite receiving equipment and to provide on-going maintenance and technical support.

Technical Evaluation

An interim technical evaluation during the first semester of delivery revealed three problem areas: audio configuration, unexpected down time, and training. A weakness in the audio configuration at the production sites was problematic. Hand-held microphones for student responses proved inadequate. Students were reluctant to use them and in-class responses were frequently missed by distant viewers. Audio levels were also inconsistent. VU meters were added to each production kit to ensure accurate on-site monitoring and adjustment of audio levels. An enhanced audio configuration is being tested in which ceiling mounted microphones are positioned to pick up student responses.

While some down time occurred due to problems with encoder/decoder devices in the fibre optic/microwave links, the majority of down time occurred as a result of inadequate communication and scheduling procedures and policies. While well established and fully

operational procedures were in place for post-secondary network delivery, new procedures had to be implemented for the secondary sector. Down time occurred, on occasion, as these procedures were implemented and adapted.

As has been demonstrated in the delivery of post-secondary courses, one of the most important support services continues to be the provision of training for individuals at receiving sites. In many instances, satellite receivers were installed just prior to course delivery. This resulted in insufficient time for people on site to become completely conversant with the equipment or for SCN to train personnel. As individuals became more adept with the hardware and gained experience in tuning to the correct satellite transponder and audio sub-carrier, operator errors decreased.

Instructional Evaluation

A comprehensive survey of pilot project participants was conducted by the Correspondence School upon completion of the first year of the project. The pilot tested the mettle of all involved as students, teachers, administrators, and technicians grappled with the technical and instructional implementation of the project. While the frustrations of start-up technical, administrative, and communication problems were evident in the survey, the role of the teacher was clearly the focus. The tele-teacher's role is perceived as multi-faceted and a critical success factor.

> The instructor is the key to success. The process can be intimidating. The instructor must have the confidence and will to control the situation and not have the situation control the individual. (SGCS Survey)

Calvert (1986) concluded that "...the introduction of any form of mediating technology requires an instructor to learn new skills to use the technology and compensate for missing cues" (p. 101). Instructional style and immediacy behaviours appear to have a direct bearing on student perceptions of a televised mode of delivery. (Hackman and Walker, 1990) Anecdotal comments in response to the Correspondence School survey addressed the role of the tele-teacher in the areas of motivational tactics, immediacy skills, pacing, and interaction.

Participants saw the tele-teacher's role as motivational, one which provided the spark or incentive for students to work and progress. Motivation appeared to be closely related to performance and interpersonal skills: "Make the broadcast more fun." Participants wanted teachers' television presentations to be exciting, dynamic, and interesting. The teacher requires "the ability to personalize the delivery" and is expected to "promote student participation and interaction." The teacher was also seen as a pacing mechanism, a means of keeping students on track and a means of reducing the isolation of the distance learning experience. Clearly, the teacher who teaches on television must possess a number of attributes which can readily be communicated through the eye of the camera.

Conclusion

The pilot project has afforded a learning experience for all involved. Technically, this mode of delivery is eminently feasible. The foundation of a network infrastructure comparable to that of the post-secondary sector has been implemented. The pilot has exposed front-line educators to the logistical and pedagogical implications of this particular method of distance delivery. Much has been gained; much more can be learned. As teachers acquire the requisite skills and experience, instruction will improve. As students develop a repertoire of independent study skills, learning will improve. As distance education becomes an integral part of the classroom experience, in whatever mode it most appropriately manifests itself, greater equity of access will be achieved.

A parent responding to the Correspondence School survey said it this way:

> I have dreamed for years of a system such as this being available in Saskatchewan, enabling any student in any school large or small to have the opportunity to take any subject offered.

That is the dream. We have the capacity to make the dream a reality.

Experimental International Language Teaching Between Japan and Australia Using 64/128 kbs Compressed Video via ISDN

Shigeru Wakamatsu* and Geoff Arger**
* National Institute of Multimedia Education
Chiba, Japan
** The University of New England
Armidale, NSW 2351, Australia

1. ABSTRACT

Language teaching between Japan and Australia using 64/128 kbs videoconferencing via international ISDN has been successfully undertaken. The trials took place in March 1991. The parties involved in the experiment were the National Institute of Multimedia Education, the University of the Air, the University of New England, Sony Corporation and Telecom Australia.

2. INTRODUCTION

In past few years, a videoconferencing system using compressed video technology with a low bit rate of 64 kbs or 128 kbs has been developed. The significance of this low speed is that it is adaptable to the basic rate interface services of ISDN. It has been developed to the stage that it is possible now to use it for interaction throughout the world.
The low bit rate videoconferencing system is increasing in popularity because of its complete interactivity in voice and picture at the highest cost efficiency, that of the cost of a standard phone call. The system was in great demand during the recent Persian Gulf War. From an educational aspect, this videoconferencing system was thought to have the potential to assist two-way teaching at a distance.

In 1988, the National Institute of Multimedia Education,Japan started to examine the educational use of the system with "INVITE 64" via NTT's ISDN services of INS-NET64, in co-operation with KDD, VIDEOCOM International Incorp. together with the University of the Air, Japan(1). As a result, it was thought that the low bit rate videoconferencing system may have an application in interactive teaching at a distance. It was particularly thought to be useful in small sized classroom teaching,group intervieving, seminar, or learning guidance. Problems were obvious in the quality of voice and motion picture but it was thought these could be improved by technologically and pedagogically development. This experiment took the initiative in world educational use of the low bit rate videoconferencing system.

The University of New England in NSW recently become one of the first Australian tertiary education institutions to install a videoconferencing system. Having already undertaken trials earlier in the use of video point-to-point links via Telecom's Iterra satellite system, the UNE commissioned Telecom to establish a trial demonstration of a 2 mbs and 384 kbs videoconferencing link in October 1989. Although participating students reported little quality difference between the two speeds, the cost difference was substantial. So, under a three year contract, Telecom was commissioned to install the 384 kbs ISDN based videoconferencing system beginning 1990. The system's core was Telecom's CLI Rembrant II/06 codec, along with a Summit system 2000 multiplexer, and a Jtec Macrospan. The system has been used currently for about 2~3 hours pere day for administrative purposes and some teaching. Inter-campus lectures have been conducted, and overseas links have been established(2).

By 1991 rapid progress of compression technology, led to new versions of low transmission rate videoconferencing system. This included a version of an acceptable picture quality at 56 kbs which has become available at a much lover price than earlier. The circumstance led us to establish trials in both Japan and Australia. The objectives of the 1991 experiment were to evaluate the acceptability of the latest 64/128 kbs videoconferencing system for Japanese and Australian distance education,as well as to determine whether Australia and Japan had the potential to assist foreign language teaching in the other country.

3. EXPERIMENTAL

The trials took place in early March 1991.

The parties involved in the experiment were the National Institute of Multimedia Education, the University of the Air, the University of New England, Sony Corporation and Telecom Australia.

3.1 SYSTEM

Tokyo site: Videoconferencing room, Sony Corp.Minatoku, Tokyo which had installed the Sony videoconferencing system including
PCS-L2000(CLI Rembrandt)codec
RCS-S1100 system controller
VID-P10 presentation apparatus

963

Armidale site: Distance Education Centre, the University of New England which had installed

- Telecom's CLI Rembrandt II/06 codec
- Summit System 2000 multiplexer
- Jtec Macrospan
- AC 1200 echo cancellor
- Dataplex modem

Each of the sites also had video equipment including a 27 inch colour monitor and a 14 inch self view colour monitor from Sony; a Sony Miller fluidmount camera; an Elmo visual presenter(Armidale only); a Sony video recorder; and an Audio Text omnidirectional microphone(Armidale only).

3.2 STUDENTS PARTICIPATION

Tokyo site: fourteen students of the University of the Air
Armidale site: sixteen students of New England Girls's School

3.3 TEACHER PARTICIPATION

Japanese language from Tokyo to Armidale: Assoc. Prof. Masako Hiraga and Assoc. Prof. Yoko Fujii of the University of the Air
English language from Armidale to Tokyo: Mr. Graham Patterson and Mrs. Ruth Nicholls of the University of New England

3.4 COORDINATION

Tokyo site: Prof. Shigeru Wakamatsu and Visiting Assoc. Prof. Geoff Arger of the National Institute of Multimedia Education
Armidale site: Mr. Stan Tonkins of Telecom seconded to the University of New England

3.5 SYSTEM ORGANIZATION

Tokyo site: Mr. Ryuji Kitada of Sony Corporation
Armidale site: Mr. Stan Tonkins of Australian Telecom

3.6 SESSION SCHEDULE

The first week was at 64 kbs and the second week at 128 kbs. There were three separate sessions at the same speed to give the evaluation credibility. Each group contained eight students.

- The first week: March 3,4,5, 1991
- The second week: March 11,14,15, 1991

3.7 PROGRAM

11:00~11:30 English language session from Armidale to Tokyo
11:30~11:45 Completion of the evaluation sheet
11:45~12:15 Japanese language session from Tokyo to Armidale
12:15~12:30 Completion of the evaluation sheet

Both sessions were often prolonged to around forty five minutes by exited interaction between teacher and student.

SA A U D SD
1.The teacher's voice was clear
2.The teacher spoke too quickly
3.I could see a clear picture of the teacher
4.The screen was large enough
5.It was easy to ask questions
6.A lot of discussion took place
7.I enjoyed the lesson
8.I understood the lesson
9.I would like more lessons like this one
10.It was just like being in a traditional classroom
11.I did not feel nervous
12.I would recommend this type of lesson to others
13.The room was suitable for this type of lesson

Strongly Agree (SA)=5; Agree (A)=4; Uncertain (U)=3;
Disagree (D)=2; Strngly Disagree (SD)=1

4. EVALUATION

4.1 STUDENTS'S RESPONSES TO THE EVALUATION STATEMENTS

The evaluation was organised using the same instrument initially developed by UNE. Japanese students's mean scores of the evaluation statements throughout the three sessions each is presented by Figure 1. Figure 2 shows the overall comparison between the mean scores of the responses of Australian and Japanese students to the evaluation statements throughout six sessions of 64/128 kbs.

4.2 STUDENTS'S RESPONSES TO THE OPEN ENDED QUESTIONS

(1) What were the good things about this lesson?

Japanese students liked being able to learn directly from foreign teacher (78%,week 2). Australian students comments were extremely positive. It is clear that this small group of students enjoyed the experience of being involved in the teaching trial. Perhaps the following comment summarises the feelings of the Australian students.

"I really like being taught from Japan. It was good fun and I think if there was more teaching like this foreign languages would be easier to learn."

(2) What could be changed to improve this lesson?

Japanese students:

a) The teacher's voice could have been more clear(week 1, 74%; week 2, 52%).
b) Would have preferred to speak without hand microphone(week 2, 21%).
c) Picture could have been more clear (week1, 17%; week 2, 12%).
d) Delay of audio could be reduced(week 1, 9%; week 2, 16%).

Australian students:

There were only two aspects of the teaching trial that several students felt could be improved. These were the seating and a greater confidence about being involved in discussion. Some students said the chairs were a bit uncomfortable and that "it is easier to concentrate when you feel comfortable". Although the Australian students indicated there was a reasonable amount of discussion, some indicated that they wanted to say things but felt uncertain as to whether they could really speak out freely.

(3) Do you think lessons like this one are valuable in foreign language teaching?

Japanese students:

Most of students said "Yes, they are valuable"(week 1, 58%; week 2, 94%).

Australian students:

The students indicated that the lessons were both valuable and enjoyable. A comment from one of the open-ended responses indicates the nature of student views. "I think we have all enjoyed these lessons.You can certainly learn a foreign language from thousands of miles away if you have this sort of television".

4.3 TEACHERS'S RESPONSES

Responses by Japanese teachers to the open ended questions were as follows.

(1) What were the good things about this lesson?

Teacher A: The layout of camera, monitor, etc. was good easy to manage. "Show & tell worked well as always.

(2) What could be changed to improve this lesson?

Teacher B: The voice quality. I heard echo very often. The time lag of the sound also could be improved.

(3) Is this type of instruction particularly suited to foreign language teaching?

Teacher A: I think it is suited more to lecture type than to interactive type of instruction. It does give students a sense of "performance" and good motivation.
Teacher B: Not particularly. Especially I don't think this type of instruction is suited to drill type of language teaching.

(4) What other subject areas is this type of instruction suited to?

Teacher A: As stated above, it is suited to lectures.
Teacher B: It is suited to cultural or anthropological subjects, international communication, cultural introductions and so on.

(5) Any other comments?

Teacher A: The three TV sessions have created a nice feeling of sharing between the students and me, which might have been difficult by postal correspondence.
Teacher B: I noticed that the participants, including the teacher shoud realize that they have to wait for the time delay after they spoke and that it is very hard to have a quick question and answer type of conversation.

5. CONCLUSION

The worlds first international video lesson using ISDN was very successful. There are a number of general observations that can be made regarding the data collected during the Tokyo-Armidale video conference link. However it seems appropriate to point out that only a small number of students were involved in the teaching trial and that the novelty of the link may have influenced the perceptions of participants. The statistical tests carried out on the data should be considered as indicative of trends, rather than conclusive outcomes.

5.1 RATING SCALE RESULTS

The following points can be made regarding the overall comparison between the responses of Australian and Japanese students.

(1) The Australian students tended to rate the items more highly than Japanese students. AS a consequence of this, there were a number of significant differences in the mean scores.

(2) Based on the mean scores, both groups of students rated the same three items most positively. These items were "I would like more lessons like this", "I enjoyed the lesson" and "I would recommend these lessons to others".

(3) The responses of Japanese students tend to indicate they did not find the teacher's voice particularly clear, the room they were in was not particularly suitable and they did not believe the instructional experience was like being in a traditional classroom.

(4) Both groups of students tended to the week 2 experience more positively than week 1. This was more marked in the Australian data.

5.2 RESPONSES TO THE OPEN ENDED QUESTIONS

Finally, responses to the open ended questions by students of both countries were quite positive. This teaching technique should create a sense of closeness by the interaction between teacher and students, nevertheless there is an inevitable "delay of sound" caused by satellite transmission connecting the two countries.

Additionally, a further pedagogical examination should be conducted regarding this technique particularly on its application to lecture type of instruction as well as to the interactive type.

ACKNOWLEDGEMENT

The authors wish to thank Assoc. Prof. Masako Hiraga and Assoc. Prof. Yoko Fujii of The University of the Air, Mr. Stan Tonkins, Mrs. Ruth Nichols, Mr. Graham Patterson of The University of New England, together with Mrs. Kumi Fujimori of The New England Girls' School for their eager cooperation.
The authors also deeply appreciate Mr. Ryuji Kitada and Mr. Yoshihiko Kawakami of Sony Corporation's helpful collaboration.

SATELLITE PROGRAM DISTRIBUTION IN THE PACIFIC

Veronica M. Ahern
Albert Shuldiner
Nixon, Hargrave, Devans & Doyle
Washington, D.C.

ABSTRACT

Recent domestic and regional satellite systems in the Pacific region have created opportunities for dramatic growth of cable programming. Proposals for additional satellite capacity hold the promise of much greater opportunities for programmers. The ability of programmers to exploit these newly created opportunities, however, will depend on the development of terrestrial policies designed to permit expanded use of satellites.

974

SATELLITE PROGRAM DISTRIBUTION IN THE PACIFIC

Veronica M. Ahern
Albert Shuldiner
Nixon, Hargrave, Devans & Doyle
Washington, D.C.

In the United States, it is generally accepted that the use of satellites for distribution of video programming was the key element in the growth and development of cable television systems. Cable News Network, Home Box Office, Turner Network Television and a host of other programming sources owe their success, in large part, to satellite distribution. It is natural, therefore, for successful programming companies to seek to expand their markets into the Pacific region using satellite distribution.

Until recently, a lack of satellite facilities, high prices for transponder capacity and the need to use relatively large receiving antennas has hindered the development of distribution channels along the lines of these domestic United States ventures. In this paper, we will explore the recent growth in the sources of existing and planned satellite capacity, the impact this has already had on the growth of cable programming outlets and some of the remaining obstacles which must be overcome before we will see a robust market for cable programming.

I. Existing Satellite Capacity

Traditionally, there have been three sources for satellite capacity in the Pacific: INTELSAT, Indonesia's regional PALAPA satellite system and Australia's AUSSAT. Although INTELSAT operates 4 satellites in the Pacific region, the high cost of INTELSAT circuits and the need to use relatively large receiving antennas, has limited

the incentives for cable programmers to exploit this capacity for distribution. CNN has been a notable exception to this rule, using INTELSAT space segment to broadcast its programming to the Pacific market for the past four years. The PALAPA system's two satellites have 24 C-band transponders and have provided Indonesian and regional service on a limited basis, but, until recently, had failed to attract significant attention due to the need to use relatively large and expensive receiving antennas. AUSSAT's satellites have provided extensive television coverage but are limited to Australia and New Zealand.

The recent introduction of new satellite capacity in the Western Pacific has dramatically changed the picture for cable programmers. The launch of the Japanese direct broadcast satellites and the AsiaSat 1 satellite focused attention on the demand for sophisticated and diverse programming throughout East Asia and the Pacific. Although the failure of the Superbird satellites was a

significant set back for the Japanese direct broadcast satellite industry, Japan Communications Satellite Co. (JCSat) has successfully introduced services on its two JCSats. The JCSats provide 32 Ku-band transponders covering the main Japanese islands. Located at 150°E. and 154°E., these satellites have been operating at full capacity due to additional traffic picked-up after the 1990 in-orbit failure of Superbird A. Space Communications Corp., owner of the Superbird satellites, plans to launch two replacements in 1992 which will introduce additional capacity for broadcasting.

The launch of AsiaSat 1 in 1991 has had an even more dramatic impact on public perception of satellite distribution of programming. AsiaSat 1's two beams cover China and East Asia stretching west to Pakistan and the Middle East. Up to 12 of the 24 C-band transponders on the satellite are available for Hutchison Whampoa's HutchVision STAR TV regional television service. STAR TV

commenced service in August 1991 with its twenty-four hour a day Prime Sports channel. STAR TV added MTV Asia in September and a Mandarin Chinese-language channel in October. Most recently, STAR TV added a twenty-four hour a day English language news program in conjunction with the BBC. The introduction of these new programming sources, has sparked renewed interest in the traditional sources of satellite capacity as well. Indonesia's PALAPA B2P satellite has recently been chosen for distribution of ESPN, and CNN has moved to PALAPA from INTELSAT. Most recently, PALAPA announced an arrangement with Hong Kong-based Business News Network for broadcast of an all business and financial news station. With its coverage of Southeast Asia, parts of China, the Philippines and Indonesia, the PALAPA satellite provides a significant complement to the service provided via AsiaSat 1.

II. PROPOSED SATELLITE SYSTEMS

The successful implementation of even a small number of the proposed satellite systems for domestic, regional and international service in the Pacific and East Asia will create even more incentives for cable programming distribution in this region. The announced proposals include the following:

- Unicom Satellite Corp.

  Unicom has two separate proposals for entering the satellite market in the Pacific. Under the first scenario, Unicom will operate two satellites in orbital positions assigned to the Republic of Tonga's Tongasat system. Unicom has proposed a 1994 launch of the first of these satellites for Pacific and international service. A second satellite for domestic and regional service in Asia is proposed for 1995. Each satellite will carry 12 C-band 36 MHz

transponders capable of servicing 3 meter antennas and 6 Ku-band 72 MHz transponders operated as 12 36 MHz transponders capable of servicing 1.8 meter antennas.

Unicom has also applied to the Federal Communications Commission for authorization to assume McCaw Space Technologies, Inc.'s conditional authority for a U.S. authorized separate international satellite system serving the Pacific and Indian Ocean regions. Unicom proposes to convert McCaw's authorization for two satellites over the Pacific and Indian Oceans into two paired "lightsats" at 170° E. and 70° E.

- PanAmSat

  The Federal Communications Commission has granted PanAmSat's application for its fourth

satellite, PAS IV, to be located at 192° W. PanAmSat plans to launch the hybrid satellite in the second quarter of 1994. With up to 48 transponders proposed, some at high power, this satellite will offer trans-Pacific service to small receiving antennas. PanAmSat also plans to launch a second Pacific region satellite, PAS V, for operation at 194°W.

- South Korean Domsats

  The government of South Korea has recently entered into a contract for construction of two satellites which will comprise the country's first domestic satellite system. Each satellite will contain 12 Ku-band, 12-watt transponders for domestic communications and 3 120-watt transponders for direct broadcast television service.

9 32

- THAISAT

  Thailand has proposed to launch its first domestic satellites in 1993. Each of the two initial satellites will carry ten C-band transponders and two Ku-band transponders.

- MEASAT

  Bina Riang Pte. Ltd. of Malaysia has announced a 1994 launch date for the Malaysian East Asia Satellites. The MEASAT system will be composed of two satellites based on the same design adopted for THAISAT.

- PacStar

  PacStar, a regional satellite system proposed by Pacific Satellite, Inc., is scheduled for launch in late 1993. The first two planned

satellites each will include a yet to be determined number of C- and Ku-band transponders, with EIRP levels higher than INTELSAT, AsiaSat, and PALAPA. PacStar plans to provide service to the east and west rim of the Pacific basin and the south Pacific islands. High power spot exams would provide service to the more populous South Pacific islands and Papua New Guinea.

- Columbia Communications

  Columbia Communications has the right to use the C-band capacity (12 36MHz transponders) on NASA's Tracking and Data Relay Service Satellite (TDRSS) located at 174°W. Although it provides only limited capacity, the TDRSS paired downlinks can provide coverage to Northeast Asia and the Northwestern United States.

- AUSSAT and Telecom/OTC

  With the restructuring of the Australian telecommunications entities, it is unclear what role satellites will play in the future for Australia and New Zealand. The launch of the AUSSAT "b" series in 1992 will offer new satellite capacity. It remains to be seen what path will be followed, however, as AUSSAT's new owner, Optus Communications, redirects the company's efforts towards broad-based competition with Telecom/OTC. Similarly, the desire of Telecom/OTC to enter the satellite business is unknown at this time.

Although there are a number of proposed satellite systems that have been announced, it remains unclear whether video distribution will be a major source of business for these satellites. The experience in the United States has

demonstrated that the growth of domestic systems has encouraged video distribution, particularly because satellites are an extremely efficient vehicle for multipoint delivery. Moreover, because video signals use significant amounts of transponder capacity, video distributors should be attractive customers for these systems. In conjunction with this discussion of satellite capacity, outline below are terrestrial issues which may become more important to broadcasters as distribution systems in the Pacific region develop.

III. TERRESTRIAL CONSIDERATIONS

With the growth of distribution options, programmers will need, more than ever, to address the terrestrial barriers to distribution which still exist. Traditionally, many Asian and Pacific countries have sought, for either political or social reasons, to restrict the distribution of information. The introduction of

satellite-based broadcasting has already challenged these attempts but has given some governments renewed determination to continue terrestrial restrictions on programming.

The need to coordinate terrestrial and satellite policies was illustrated by recent controversies in Japan and South Korea. The introduction of satellite broadcasting for Japan has troubled South Korea which received spill-over signals. Charging Japan with cultural imperialism, South Korea has pressured the Japanese broadcasters to modify the satellite footprint to reduce the strength of the signal received in South Korea. Similarly, Japan has objected to the reception throughout the Japanese islands of BBC programming from AsiaSat 1. The introduction of new domestic and regional satellite systems will tend to increase these claims as countries struggle to retain their cultural and social independence in light of the increasing internationalization of the distribution of information.

Various approaches have been adopted to prevent unwanted reception of satellite signals. Malaysia, for example, has renewed its ban on TV Receive Only (TVRO) antennas. Japan continues to restrict small DBS receive antennas. However, the introduction of smaller antennas and higher-powered satellite signals reduces the effectiveness of these efforts to restrict reception and make it more likely that an increasing number of illegal receive antennas will become available in these countries.

Even if distributors overcome these social and political problems, financial barriers to distribution may present more formidable challenges for broadcasters. Lack of compatibility between satellite systems has already resulted in an inability to receive multiple satellite signals. For example, to receive both AsiaSat and JCSAT programming, a subscriber would need separate antennas and tuners. The additional cost of equipment, when combined with subscription fees, may place most programming beyond the reach of viewers.

Similar concerns are raised by the issue of signal scrambling. Failure to scramble the AsiaSat signal has created a disincentive for programmers to broadcast using this satellite. Yet, introduction of incompatible scrambling systems may exacerbate the already confusing pattern of broadcasting. The introduction of new satellite systems can only lead to more confusion. Hence, a growing awareness in the future that more attention will need to be devoted to coordination of satellite and terrestrial policies will enhance the ability of this industry to grow.

IV. CONCLUSION

The growth in popularity of satellite broadcasting has focused much attention on the potential for growth in this market to satisfy the large consumer demand. New satellite proposals promise to meet the projected demands but the growth of opportunities will continue to raise challenges for programming distributors.

COMSAT'S ROLE IN THE PACIFIC:
THE ADVANTAGES OF THE GLOBAL NETWORK

a Speech by

Betty C. Alewine
President, COMSAT World Systems

Pacific Telecommunications Council Conference
January 13, 1991

Good morning ladies and gentlemen. For the first few moments of my speech today, I'm going to talk about "it". Now what is "it"?

It was praised for its role in liberating Kuwait. It helped spread the seeds of democracy in what used to be the Soviet Union. Two years ago, it received rave notices for drawing the world's attention to Tiananmen Square. It even helped tear down the Berlin Wall.

I am, of course, talking about the global communications network. While it has played a part in historical political change, it has also contributed significantly to the "economic miracle" of the Pacific Rim. That's why I am here today and delighted to participate in a discussion of the global network and COMSAT's role in bringing its advantages to this region.

Over the past two decades, the nations of the Pacific have forged the fastest industrial revolution the world has ever seen. Just since 1985, these countries have enjoyed the highest economic growth rates in the world, ranging from 4 percent in Japan to 10 percent in Thailand. And the miracle is far from over. Some say it is accelerating and predict that by the year 2000, the combined economies of the Pacific will reach $13 trillion, twice the size of post-1992 Europe.

Many factors have contributed to this remarkable economic performance. Among the most important are the declining costs and improving quality of international telecommunications. For countries depending on exports for growth, efficient and reliable communication with trading partners is essential. Taking note of the success of Japan, Korea, Hong Kong and Singapore, governments in the rest of Asia have begun to act on the idea that the country with the best infrastructure and access to the global network will attract the most foreign investment, manufacturing and financial institutions. No wonder modernization of telecommunications has become a national priority in Thailand, the Philippines, Indonesia, and Malaysia.

The tremendous growth in demand for telecommunications has attracted all kinds of international service providers to the region, each striving to deliver the best quality at the lowest

price. Recognizing the value of competition to the end-user, governments are deregulating telecommunications markets. By increasing competition, they want to further accelerate the growth in services that are so desperately needed.

Their efforts are paying off. Intense competition is driving down prices and expanding choices for both consumers and business users. Today, international users have a lot to choose from. In addition to the global network of INTELSAT, on which COMSAT provides services to and from the United States, there are regional satellite systems and fiber optic cables.

To get an idea of how important the Pacific Region is to COMSAT, consider these trade statistics: Trade between North America and the rest of the Pacific Rim was worth $20 billion in 1970. By 1990, it had increased more than ten-fold to $275 billion. To emphasize the opportunity this represents for U.S. firms, the former governor of California, George Deukmajian once said, "There is a $3 trillion market our there, and it's growing at a rate of $3 billion a week."

That volume of business has to be supported by the kind of efficient, reliable and affordable communications between the U.S. and the Pacific that COMSAT can provide.

Our international business service (IBS) in the Pacific has been growing at a rate of about 25 percent annually since 1988. In spite of alternative transmission options, growth remains strong. Even as I speak, we are in the process of implementing 24 IBS circuits worldwide. Ten are in the Pacific. These new circuits will serve customers in Australia, New Zealand, Guam, Hong Kong, Singapore, Malaysia, and the People's Republic of China.

The broadcast side of our business is equally exciting. International satellites are uniquely qualified to support increasingly sophisticated requirements for satellite news gathering and program distribution. In 1991, the number of occasional-use hours leased in the Pacific increased by 600 percent, in part because of the Persian Gulf War.

Full-time leases have also increased in the region because market conditions have changed. In Japan, for example, broadcasters, previously covered by one pooled lease, now each have their own 24-hour leases. They have all installed customer-premise antennas, so individual leases are more convenient.

But the size and diversity of the market isn't the only thing that's important to us about the Pacific. Here, we can put to work the full range of services and capabilities that distinguish COMSAT from the competition.

You may be expecting me to elaborate on this point by reciting COMSAT's technological achievements that have made

satellite communications the robust business it is today. True, we still exploit all the latest technological innovations to ensure satellites a position in the networks of the future. But COMSAT is no longer the technology-driven company it was when it started out in the 1960s.

Then the company was armed with a good idea, the technology to make it real, and the determination to awaken the market. Today, the market has its own momentum. Customers want to move information, whether it's voice, data or video. They don't care how they send and receive it -- by satellite or cable -- as long as their service is cost-effective and reliable, and there when they need it.

Recognizing this fundamental change in the market, COMSAT has changed, too -- changed the way we manage and operate our business. Today, the requirements of our customers drive our business. Technology and the regulatory environment are, of course, important factors in what we are able to do, but neither is the driving force. Our job is to provide service on the INTELSAT global network to and from the United States. The way we convert our customers' needs into services on that network, or into satellite investments for the future will determine our success in the competitive marketplace.

Focusing first and foremost on our customer needs is the only way we can meet the competition head on. This focus demands that we manage and operate our business to deliver consistently high quality services that are affordable, flexible, easy to use and reliable. It permeates every single facet of our business -- sales and marketing, new service development, operations and engineering, technical services, pricing and billing.

Let me explain from a management perspective how this has changed COMSAT. Let's start with affordability. Price may not be the only factor in a customer's decision, but in a competitive market, we don't expect to get past the front door without a competitively-priced service.

From the beginning, COMSAT has continually passed on to its customers the benefits of economies of scale inherent in newer satellites and the savings made possible by digital technology. Market forces also affect our pricing.

Earlier this month, for example, we lowered our rates on international digital-switched voice services by as much as 58 percent. This, of course, depends on the duration of the contract and the volume of business in each of four region, one of which is the Pacific. With this new tariff, we are quite competitive with fiber optics cable to many Pacific locations. We are also ready to compete with the new lines scheduled of the future. The message to our customers is clear: We are going to

compete aggressively for your business today and for a strong share in future growth.

We have also extended a promotional tariff for our IBS customers in the Pacific Region, offering a discount to those who make the most efficient use of satellite capacity.

And, last year, we lowered occasional-use television rates to enhance this increasingly popular service. Rates on the first ten minutes on primary and major path satellites have been reduced by 12 percent. Rates on each additional minute have been lowered by the same amount.

With our focus on customer requirements, we also began about five years ago to alter our approach to sales and marketing. Everyone -- let me repeat, everyone -- in COMSAT World Systems is part of our sales force, directly or indirectly. We have instituted an account management organization so that each customer has a single point of contact. You make one phone call, and the account manager takes it from there, coordinating the technical and operating resources needed to solve your problem.

The account managers are the ears and eyes of our corporation. What they learn from our customers translates into improvements in services as well as plans for new satellites.

We augment individual contact with special meetings. For example, each year COMSAT hosts a User-Provider Meeting for our broadcast customers. The meeting is an annual opportunity for customers to talk openly about their problems, not only with COMSAT managers, but also with representatives of other INTELSAT signatories. We started the User-Provider meetings five years ago with 20 people sitting around a table. In 1991, 150 participants attended. It has evolved into an annual institution.

The success of the User-Provider meetings for our broadcast customers led us to undertake a similar effort for customers on the pure voice and data side of the business. The first conference of this type was held in December, and we plan another in October 1992.

Regional meetings are also essential. Some of you may have attended the Pacific briefing held jointly by our marketing, sales, and operations staff last September here in Hawaii. That meeting focused on the particular concerns of carriers serving the Pacific Islands. The main topic was digital services. As a result of the discussions, digital implementation went more smoothly for these customers in the fourth quarter. And we ended up with three new contracts for long-term service.

We incorporate what we learn into the development of new

services. VSATs are an excellent example. Given the huge popularity of VSATs in the United States, and the availability of higher-powered satellites to transmit to small antennas, it seems only a matter of time before the international VSAT business will take off, too. Recognizing this market potential, COMSAT introduced a VSAT tariff in December.

I am also pleased to announce we have just filed with the FCC to start a digital audio distribution service in February. This new service caters to the emerging international direct-to-cable audio market. The potential of digital audio is exciting. Imagine receiving hundreds of CD-quality programs from around the world, live, via satellite, through cables into your home. So that our customers can test-market the service, COMSAT will offer promotional rates for up to six months of trail use.

We continually adapt our existing services. Five years ago, a customer had few choices in the kinds of leases that were available. Today, we offer a complete menu of services -- long-term, medium-term, short-term, and occasional-use.

In 1988, we established a technical service department which provides the operating expertise to solve client problems identified by sales and marketing. At the Seoul Olympics, for example, COMSAT technical service and sales staff worked on-site, in coordination with KTA and INTELSAT, to support our network and other customers. Building on the first-hand experience gained spending long hours in the international broadcast center in Seoul, we are well along in our plans for this year's winter and summer Olympics in Albertville and Barcelona. A COMSAT team of sales and technical managers will once again provide on-site support in cooperation with the host signatories.

Then there is responsiveness to the unexpected. On December 7, 1991, a Japanese television network wanted to broadcast the Pearl Harbor Commemoration ceremonies held not far from where we sit today. Unfortunately, all normal satellite channels between Hawaii and Japan had already been booked. We at COMSAT understood the importance of the event being broadcast, and solved the problem by beaming the ceremonies on an available channel to the U.S. and then beaming that signal to Japan on another satellite. Through this creative solution, we were able to give Japanese viewers instantaneous access to what they wanted to see.

Another service that exemplifies our flexibility is cable restoration. Although cable operators compete with us on heavily used routes, we also consider them good customers. Even heavily-armored fiber cables sometimes fail. When that happens, COMSAT, through INTELSAT, quickly restores traffic usually within an hour of the outage. In 1991, alone, we restored cable traffic on 14 separate occasions amounting to 191 days of cable restoration

service. That's half a year.

We have also made our services easier to use. In 1989, we inaugurated a computerized ordering system called COMSAT Television Scheduling Service, or CTVS. Occasional-use customers can access instant information on earth station and satellite availability in the INTELSAT network. They also find up-to-date information on earth station capabilities, satellite configurations, and international broadcast rates. Today, more than half our normal business inquiries for occasional-use services come through CTVS. And we are continually upgrading the system's capabilities. In the near future, we will add a "bulletin board" feature to announce new satellites, rates, special events and other news.

Lastly, how have the changes at COMSAT affected the way we do business through the INTELSAT organization?

In my view, there is no effective substitute for the global network that years of successful cooperation among diverse interests have achieved. Together, the signatories of INTELSAT have built a great foundation. With that foundation and the additions we make to the network in the future, each signatory is able to offer top quality service to its customers.

Most INTELSAT signatories face the same market forces we do. National governments are deregulating many businesses. Some are moving more quickly than others. But the direction is clear. Governments are trying to create regulatory frameworks that allow market forces to function more freely for the benefit of the consumer.

Whether you believe that regulation protects or hinders, we all must win business today in the marketplace, and we must win it competitively.

Perhaps the most critical issue within INTELSAT today is that of satellite capacity -- how much is needed, where, when? This is a business decision. Our approach begins with the customer focus I have just described. COMSAT and INTELSAT will make sure our customers' requirements are well reflected in the services we introduce and the investments we make in new satellites, such as the INTELSAT VII series.

The INTELSAT VIIs, scheduled for deployment in 1993, are the first satellites designed specifically for the Pacific market. And we are excited about its capabilities such as enhanced coverage, power and connectivity, plus the ability to work well with small antennas.

Even before the VIIs are launched, we are working with INTELSAT to prepare for the post-1995 era. At INTELSAT's

December Board of Governors meeting, we approved the issuance of an RFP for follow-on satellites. We are also considering alternative designs specifically targeted toward markets that are best suited to use satellites. This is especially important in the Pacific, where geography is so conducive to satellite communications.

Today, routine news events are transmitted instantaneously throughout the Pacific. Stock markets in Tokyo, Taipei and Hong Kong rely on rapid data transfer. Everybody, it seems, has his or her own fax machine. Personal overseas communications have never been easier or more affordable. Whether it's a Persian Gulf soldier using digital voice service to phone home during the Gulf War or a sports fan thrilling to an Olympic event half a world away, satellite communications have changed all our lives.

In closing, I have to tell you, it's wonderful to be here in Hawaii, away from the pressures of my office. It's great to look out over the water and see nothing but, well, water. For a minute or so, we feel peaceful, separated. But when you think about it, even though we're here on an island in the middle of the Pacific Ocean, there are no islands anymore.

What's most thrilling about satellite communications is that our customers and users can take advantage of amazing technological achievements without thinking twice. All of us today will phone home, click on television, or transmit a fax. We are really just next door to our loved ones and business associates.

Thanks to the global communications network, we are all linked together. Almost wherever we go, in the Pacific or around the world, we're becoming one big community. The challenge for COMSAT is to make sure that billions of people can be part of that community. I guarantee that we will continue to do just that.

Thank you very much.

An Exercise in Privatization: The Making of Telekom Malaysia

by:

Baharuddin Aziz, Ph.D
Senior Lecturer
(Telecommunication & Film)
School of Communication
MARA Institute of Technology
Shah Alam, MALAYSIA

1. ABSTRACT

The privatization of Malaysian government-owned and operated public utilities has been a major aspect of the development agenda since the early 1980's. It was generally perceived by policy makers as the sine qua nom of the country's economic growth and future development. Among the services initially earmarked for privatization were the transport and telecommunication sectors. This article takes a retrospective look at the Malaysian government's privatization policy with respect to the formation of Telekom Malaysia and explores the telecommunication scenario vis-a-vis the biggest public-listing exercise in Malaysia's corporate history.

2. INTRODUCTION

An advertisement which regularly appears in *Utusan Malaysia*, a leading Malay-language daily, features a *tabib* (practicioner of traditional Malay medicine and other means of sex therapy) publicizing his services which purport to guarantee enhancement of men's sex life and general health. This particular advertisement would seem ordinary except that it

carries the picture of the *tabib* clutching a cordless phone close to his ear. One can easily get this picture of a high-tech traditional medicine man at work. Blessed with this new gadget, men from around the world, especially those afflicted with problems of a sexual nature, can now contact him almost instantaneously.

The above example serves to illustrate the important role modern telecommunication plays in the day-to-day affairs of Malaysians both in their private and public life. Even street hawkers nowadays take orders from their regular customers with the aid of mobile phone sets. And it is not uncommon especially for businessmen to be equipped with hand and/or car phones.

Indeed, with each passing day, new innovations accompanied by a good measure of excitement seem to color Malaysian telecommunication. Notwithstanding the availability of new and improved value-added services such as MAYCIS (Malaysian Circuit Switched Data Network) and MAYPAC (Malaysian Packet Switched Public Data Network), Telekom Malaysia's data communication services to commercial enterprises, *Telita* (videotex transmission), itemized customer billing and mobile telephony, last year (1991) witnessed events promising even bigger strides in the country's telecommunication development. Among them are:

i) the signing of the memorandum of understanding (MOU) held on the island of Langkawi which will pave the way for the launching of Malaysia's own geosynchronous satellites in 1994. The satellites, known as Measat (or Malaysia East Asia Satellites) and costing U.S$250 million, are to be owned and operated by Binariang Sendirian Berhad, a Kuala Lumpur based company. Built by America's Hughes Communications International Inc., the satellites are expected to be launched in 1994 off Kourou in French

Guyana by Arianespace of France;[1]

ii) the launching of the second phase of Telekom Malaysia's pilot ISDN (Integrated Services Digital Network) project. Initially to cover the populous Klang Valley in Peninsular Malaysia, ISDN systems are expected to be operational on a commercial basis in 1993. With the availability of ISDN -- where digitized voice, data, text and images can be communicated via a single line -- Malaysia is poised to become the third country in Asia after Japan and Singapore to provide such sophisticated circuitry;[2]

iii) the completion and launching of a submarine optic-fibre cable link between Kuantan on the east coast of Peninsula Malaysia and Kota Kinabalu in East Malaysia. This optical-fibre link is expected to enhance the quality of telephone and broadcast transmission links between East and West Malaysia and support new services.[3]

The events, each a milestone in the development and expansion of telecommunication infrastructure and services in Malaysia, were largely viewed as being the manifestation of the deregulation and privatization policies adopted by the government in the early eighties in so far as the telecommunication sector is concerned. Deregulation of the telecommunications environment had also provided the impetus for entry of locally incorporated as well as foreign-based companies to compete for a slice of certain telecommunication services like pay and credit-card phones, mobile telephony, and paging systems. Competition among the telcos has generally enhanced their productivity apart from sensitizing their staff to the importance of maintaining high-level customer satisfaction.

Rapid advancement in state-of-the-art telecommunications technology in the last two decades also dictated that the Malaysian government revamp the administrative structures and management function of Jabatan Telekom

Malaysia (JTM), Telekom Malaysia's predecessor. JTM had been the government department in charge of providing telecommunication infrastructure and services nationwide. Encumbered with administrative procedures and regulations, it was generally felt by policy makers that, as a government department, JTM would be in no position to provide a viable network let alone run a profit oriented telecommunication service for the country.

Besides the rapid advancement in telecommunication technology, there were other conducive factors responsible for the privatization of telecommunication services in Malaysia. These will be discussed in the following section.

3. PRIVATIZATION: THE BEGINNING

The thrust for the privatization of government owned and operated public services had largely come from Malaysian Prime Minister Dr. Mahathir Mohamad when he assumed the mantle of leadership in 1981 from former Prime Minister Hussein Onn. Dr. Mahathir initiated a series of policy changes -- often viewed at that time as drastic by some and with skepticism by his detractors -- viz. his Look East policy, emphasis on heavy industries, and, of course, privatization. Although critics had expressed reservations saying that "nepotism and corruption" can easily rear their ugly heads if privatization is not executed according to the book and done openly, it is generally felt that the majority of Malaysians do not want privatization stopped altogether as many consider their state-owned and run utilities inefficient.[4]

Ailing government corporations and obligations on the government's part to finance and provide certain public services strained the country's

finances. The corporatization and, later, privatization of these government entities were recognized as possible options to relieve the government of its financial burden and resuscitate some of its financially-strapped corporations and utility providers. Futhermore, the onslaught of recession in 1983 convinced the Mahathir Administration that the private sector should be accorded a bigger role in the provision of social services and amenities and hence reduce government expenditure on such services.

The Cabinet entrusted the Economic Planning Unit (EPU) of the Prime Minister's Department with the task of coming out with a comprehensive national privatization masterplan, one in which the government envisages should:".....enhance the role of the private sector in the economy while at the same time creating new opportunities for the public, in particular the employees of the privatised projects as well as the Bumiputera community to own wealth through the purchase of shares in these projects".[5]

3.1 **Privatization: The role of the EPU**

Privatization, by the end of the 1970's was becoming an international catch-cry and Malaysia, which did not lose time in recognizing it as an instrument for spurring economic growth, co-opted it into its development agenda. The Economic Planning Unit (EPU) of the Prime Minister's Department set to work out the best possible privatization formula that took cognizance of the country's development goals and priorities. Based on an analysis of two EPU publications focusing on implementation guidelines of the policy,[6] privatization's major guiding principle can be summarized as follows: provision of strategic services in an efficient, profitable manner but without sacrificing public needs and jeopardizing the interests of the ruling political party.

Identification by the EPU of potential candidates for privatization got underway in 1982. Among the earliest to be identified were the Malayan Railway, the Port Klang Container Terminal, National Padi and Rice Board's rice milling complexes and the Royal Malaysian Navy Dockyard located in Lumut. This was followed by moves to corporatize and then privatize the National Electricity Board, the Telecoms and Postal Departments. Up till the end of 1991 and since the formal implementation of the privatization policy in 1983, 37 projects have been privatized, 27 of which were once government entities but now taken over by private companies either through outright management buy-outs or by sale of equity or assets to the public. The government earned U.S$437 million through sales of its interests in entities which it had owned and, more important, was financially relieved of some U.S$3 billion when it no longer has to fund infrastrusture development and operating expenses.

The EPU subscribes to two other basic types of privatization implementation methodology: "Build-Operate-Transfer" (BOT) and "Build-Operate" (BO). The BOT concept requires interested companies to submit proposals. If approved, the company constructs the facility with its own funds and is allowed to collect revenues from users over a specific period of time. The construction of highways and collection of toll is an example of this. The BO scheme is largely similar to BOT but the company concerned does not transfer its assets or facility to the government. An example of BO is Sistem Televisyen Malaysia Berhad (STMB). Granted a license by the Ministry of Telecommunications, Post and Energy in 1985, it now operates a private commercial TV station (TV-3) nationwide. STMB's ownership, however, is closely linked to the investment arm of UMNO or United Malays National Organization, the major component of *Barisan Nasional*, the ruling

coalition, as well as to other organizations linked to the other leading political parties in the coalition.

Besides recommending government entities for possible privatization to the Cabinet, the EPU also reviews proposals from various private companies keen to take over state-owned and operated entities. The process, as illustrated in Figure 1 (see next page), also involves the appointment of consultants to undertake a feasibility study once a proposal is submitted via the EPU to the Cabinet. Based on the respective consultant's appraisal and recommendations, the Cabinet would then seek passages of legal amendments to existing statutes like the Pensions Act of 1980, the Telecommunications Act of 1950 and the Electricity Act of 1949 in order to facilitate the smooth transfer of government assets to private companies established under the Companies Act of 1965.

Proposals to buy out or take over the running of state-owned services must take cognizance of the objectives of Malaysia's privatization policy, viz.:

a) relieve the financial and administrative burden of government;

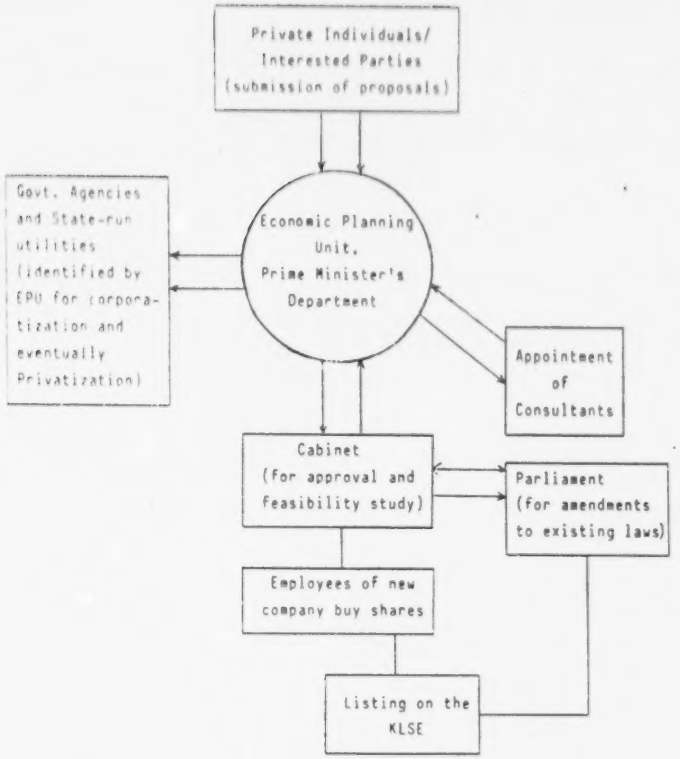
b) improve efficiency and productivity;

c) facilitate economic growth;

d) reduce the size and presence of the public sector in the economy; and

e) help meet the national economic policy targets.[7]

Reflective of the policy objective mentioned in (e), privatization also is seen as an instrument to enhance *Bumiputera* (indigenous) equity stake and participation in the corporate sector. Apart from this, employees of newly-



Steps in the Privatization Process

1. Identification by the EPU of state-owned and run utilities and services for possible privatization: Proposals submitted by interested parties to the EPU.
2. Analysis, Review and Recommendations by EPU to the Cabinet.
3. Cabinet approval; appointment of consultants
4. Cabinet proposes new laws and amendments to existing statutes for passage by Parliament.
5. New company/corporation set up under the Companies Act of 1965 to take over ownership/management of state-owned and operated agencies/utilities.
6. Sale of shares to Employees.
7. Prospectus and sale of shares to the public.
8. Listing on KLSE.

Fig. 1: Major Entities and Steps in the Privatization Process

privatized entities are expected to gain from higher remuneration and benefits concomitant to the implementation of various incentive schemes which otherwise are not usually found in government departments and agencies. They can own a part of the company through such schemes as the Employee Shares Ownership Plan (ESOP) and Management Employee Buy-Outs (MEBOs) as prescribed in the privatization masterplan.

As for foreign ownership, certain conditions apply, particularly in terms of the value and amount of equity held in a company, which must not be in the majority. Foreign ownership is allowed only if its:

a) expertise is needed to upgrade efficiency and such expertise is not available;

b) participation is necessary to promote the export market;

c) purchase of shares will help supplement the supply of local capital; and

d) participation will enhance global linkages and international exposure.[8]

The next section looks at the biggest transfer exercise of public assets and services to a largely government-owned company as well as the largest public listing exercise in Malaysia's corporate history. It also offers a brief assessment of Telekom Malaysia's performance besides exploring the company's prospects in the near future.

4. TELEKOM MALAYSIA: PERFORMANCE AND PROSPECTS

The Malaysian telecommunication environment was poised to enter a new era of growth and expansion when, in 1987, the government transferred JTM's assets and operations to a corporation known as Syarikat Telekom Malaysia (STM).[9] The transfer not only heightened public

expectations at home but also attracted the attention of foreign investors. Malaysians, not unlike the foreign investors, expected an overall improvement to their telecommunication services, albeit, shorter waiting periods for telephone installations and repairs.

Apart from this, an important pre-requisite to more foreign investments into the country is an efficiently-run and up-to-date telecommunication infrastructure and related services. The desire to enhance connectivity to the transnational corporate structure and to keep pace with modern information and communication technology spelled the creation of a carrier unshackled by cumbersome government procedures. Hence, the move to inevitably privatize JTM.

4.1 Floatation of Telekom Malaysia Shares

Three years following JTM's "corporatization", the new company, STM, was ready to have its shares listed on the Kuala Lumpur Stock Exchange (KLSE).[10] A total of 470.5 million new ordinary shares -- representing 23.8% of the corporation's issued and paid-up capital -- were floated in September 1990. The issue price was M$5.00, or approximately $U.S1.80 per share, which was thought to be rather high for an introductory issue. At the end of the day, the sale of its shares was oversubscribed by only 1.03 times, a figure far below what industry analysts had expected. Hesitations were largely attributed to uncertainties in the Middle East (Iraq's invasion of Kuwait) and Malaysians typically saving up for incidental end-of-year expenses.

In line with the government's policy of enhancing indigenous equity stake, Telekom Malaysia reserved slightly more than 30% of the issued shares to *Bumiputera*-related institutions and individuals. Five-percent

were allocated to foreigners while another 15% were meant for its employees and eligible employees of JTM. Through what was known as "pink forms", employees, nearly all of whom had opted to serve with Telekom Malaysia, were privileged to purchase their company's shares. Almost all did but some resold them hoping to make quick gains when Telekom Malaysia share price fetched U.S$2.40 per unit on the KL bourse. This unforseen behaviour on the part of the employees later led the Economic Planning Unit to co-opt the Employees Share Ownership Plan (ESOP) into its privatization policy. ESOP involves the setting up of a trust to hold shares for employees. With such a scheme, employees can only sell their shares when they leave the company or when they retire.

Based on Telekom Malaysia's 1990 Annual Report, the government of Malaysia, through a body corporate established under the Minister of Finance (Inc.) Act, 1957, holds the majority or 76% (slightly worth more than one-half billion U.S. dollars) of Telekom Malaysia shares. Individuals from Malaysia own 3.3% of the total share value (or U.S. $24.5 million) and foreigners, including Singaporeans, 3.7% or U.S.$27.3 million (see Appendix 1).

4.2 Telekom Malaysia's Performance: An Overview

If profits are any measure of Telekom Malaysia's performance, then the telecommunication behemoth is, indeed, a success story. Telekom Malaysia has in the last three years been viewed as a national phenomenon: the flagship of the government's privatization policy. Figure 2 indicates the extent of Telekom Malaysia's steady gains in its pre-tax profits since corporatization in 1987. Since then, the government has, as an incentive, not taxed Telekom Malaysia's earnings and this, analysts say, remains an

important stabilizing factor of the company's share price on the KLSE. Telekom Malaysia's share price rose to a high of U.S$4.50 in May, 1991

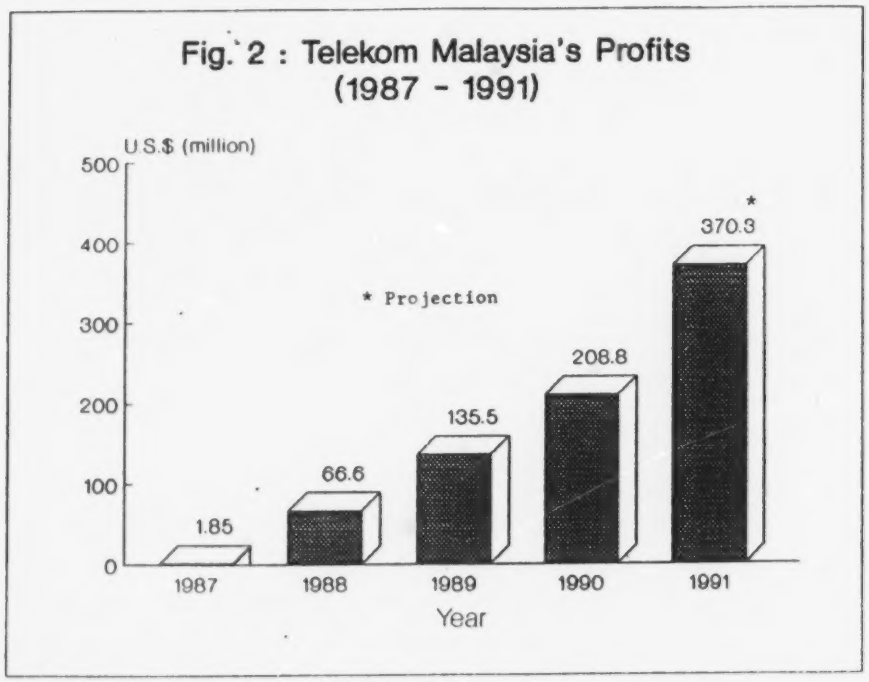


Fig. 2 : Telekom Malaysia's Profits (1987 - 1991)

only to ease off at U.S.$3.70 at the end of the year, far below that of U.S.$7.40, a price stock marketeers predicted the shares could fetch but never did. Nonetheless, the company expects to achieve an unprecedented pre-tax profit of U.S$370 million for 1991.[11]

Apart from making available an array of sophisticated digitized data communication services as well as domestic and international toll-free dailing, waiting period for phone installation has also been cut from six

months to roughly two weeks since the company's inception in 1987. Telephone density per 100 inhabitants, too, has risen from 6.8 in 1982 to 9.2 in 1991. With steady increases in line installations, the company expects to increase density to 25 by the year 2000, thereby inching Malaysia closer to the ratio achieved by developed countries. Hopefully, services, especially that of residential telephones, will be equitably spread nationwide. Presently, telephone density and various other value added services are concentrated in major cities. Those in rural areas (where density is two per 100 inhabitants) often complain of difficulties of access to good, working telephones. Despite the shortcomings, it is, however, heartening to note that Telekom Malaysia is allocating U.S.$630 million to expand and upgrade rural telephony during the Sixth Malaysia Plan period (1991 - 1995). And over the same period, too, about U.S.$3.70 billion worth of capital investment will be made mostly by Telekom Malaysia to upgrade and maintain telecommunication infrastructure in Malaysia, making it one of the fastest and largest growth market for telecommunication equipment in the Asia-Pacific region.[12]

5. CONCLUSION

We are said to be entering the Information Age -- an era characterized by the synergy of tele-communication technologies and computers continually transforming the manner, speed and volume by which data, voice and images are communicated across the globe. The rapid advancement in communication and information technology especially in the last two decades had necessitated a re-examination of telecommunication policies both in developed and developing countries and the fine-tuning of regulatory frameworks governing their use.

In Malaysia, apart from the rapid advancement in telecommunication technology, other factors have spurred the privatization of the country's telecommunication services, viz.:

i) the need to enhance connectivity to the transnational corporate structure and the global marketplace,

ii) the government's own need to relieve itself of the burden of expenditure on public utilities, and

iii) the need to enhance indigenous ownership of the country's corporate wealth.

One of the bigger challenges facing Telekom Malaysia is ensuring proper balance between an efficiently-run, profit-oriented company and commitment to social needs and public interest. As for the former, Telekom Malaysia has proven itself reasonably well judging from:

i) steady increases in profits made since its inception in 1987,

ii) its shares are viewed by industry analysts as growth utility stock, and

iii) its ability to settle outstanding loans.

As for meeting social needs, much is left to be desired. Rural telecommunication is in dire need of improvement let alone expansion. Much of the advanced services are urban-centered, mostly catering to the needs of the mercantile community. In the educational sector, it is felt that Telekom Malaysia should chart a more visible and active role toward enhancing education via use of its own array of telemedia delivery systems. Academicians in the country feel that the new video teleconferencing facility which Telekom Malaysia plans to introduce will cater more to the needs of the corporate world. What is needed then is closer cooperation between

Telekom Malaysia and institutions of higher learning and strategic planning that would enhance distance learning and telelectures through the videoconferencing mode.

In their study of ASEAN's telecommunication policies and trends in infrastructure development, Hukill and Jussawalla (1991) felt that network expansion in the country is bound to put pressure on traditional culture as westernization gets the better of Malay/Muslim values and as such could prove destabilizing to Malaysia's multiracial polity.[13] While this may be a legitimate concern, but this writer, reverting to the story of the *tabib* with which he began this paper, is inclined to believe that what is important is the harmonious blending of modern technology and the utilization of new information and communication technologies to also suit local needs and values. The case of the *tabib* (traditional Malay medicine man) serves to illustrate this point.

With expanded networks and the globalization of telemedia delivery systems, Telekom Malaysia should cooperate more closely with the local entertainment and cultural industry and assume a catalytic role to balance out the flow of entertainment, knowledge and information-based products -- which has long been in favor of the developed Western countries -- at least within the Asia Pacific region.

All said, the telecommunications sector in Malaysia is certainly poised for further expansion as the nation's economy continues to show signs of stable growth. Telekom Malaysia is expected to assume an important pivotal role in the nation's economic growth and in tandem with the nation's aspirations of becoming a significant player in the international marketplace and achieving developed country status by the year 2020.

The Need for a Universal Response to Disaster Relief

Prepared for the Pacific Telecommunications Conference
January 15, 1992

Louis Bransford
Bert Cowlan

Abstract

If society is to deal adequately with the tyranny of disaster, there is an urgent need to find and test new technologies which can survive both the forces of nature unleashed or those disasters assisted or produced by man-made means. The need for information: more, better, accurate, reliable, timely, available, affordable, arises time and again in the deliberations of organizations concerned with disaster communications. Most existing telecommunications systems are subject to vulnerabilities of size, survivability, affordability, portability and ease of use in a disaster situation. Some require external power sources; some are too large to be quickly put in place; and some need time-consuming governmental approval to be deployed. In most instances, throughout the developing world, these large, cumbersome packages are too expensive to be stockpiled where most apt to be needed. The new technological movement predicated on widely disbursed personal communication units fills a need in disaster communication and is the subject of this paper.

Introduction

Cyclones, hurricanes, typhoons, floods, tidal waves, earthquakes, forest fires, mud slides, volcanic eruptions, tsunamis, drought, tornadoes, water pollution: these constitute a litany of natural disasters that has plagued the earth from its genesis. Add to this ship, plane and train wrecks; nuclear accidents and war; acid rain and other man-made catastrophes from which no nation is safe.

Many of the disasters enumerated above are common to this part of the world in which we are gathered. As this is being written, Guam is still recovering from a typhoon that struck with 150 mile-an-hour winds.

A few months ago, speaking to the General Assembly of the United Nations, President Bailey Olter of the Federated States of Micronesia spoke eloquently of the island nations' fear of global warming and a subsequent rise in the sea level which would

literally wipe out the low-lying atolls which constitute many of the countries of the Pacific Basin.

The thousands of small islands, far from each other and prone to natural disasters, that dot the vast expanse of the Pacific Ocean, have strongly expressed their point of view towards improved disaster communications.

> "A communication system can be an instrument of great influence...no one should question the need for a reliable telecommunication service. Links between our islands are virtual lifelines."
>
> Ratu Sir Kamisese Mara
> Prime Minister, Fiji

The Role of Communications

Disasters throughout the world are compounded when communications systems and services are either non-existent or disrupted. The need to communicate: to warn people of impending disaster, to coordinate and manage relief operations, to report to the relief agencies and the general public, requires universal, flexible, portable, efficient and affordable technology.

When disasters build up slowly there are, fortunately, tools to detect them. However, when disaster strikes with the speed of a typhoon, a volcanic eruption, or an earthquake, the need for assistance is immediate. In either case, especially in the developing world, which has the least means to detect and manage disasters, the most urgent need by those mandated to provide assistance and relief is for information. (What has happened? What is needed? Where is it needed? What roads or airfields or ports or supplies are left passable and intact? What information needs to be shared? With whom?)

The world's response to disaster has been generous regardless of political divisions, diversity, or disagreements. The best of intentions have often gone begging because communications systems, the nerve center of disaster warning, assistance, management and relief, are often a first victim. Power stations fail and power lines go down. Large satellite antennas often are inoperative in gale force winds. Personnel cannot reach their duty stations. Today, there is no universal, affordable and reliable communications system that can be activated on short notice.

The United Nations and the Relief Agencies

Leading relief agencies, such as the United Nations Disaster Relief Organization (UNDRO) or the International League of Red Cross/Red Crescent Societies, or the host of other governmental, nongovernmental and private voluntary organizations, all eager and able to help, lack information and emergency communications service. The literature of disaster relief abounds with too many well-meaning efforts, which have resulted in personnel and supplies being sent to the wrong place or of the wrong kind for the needs of the specific area or never arriving because directions were never made clear. Portable communications, unencumbered by terrestrial mishaps presents a viable

alternative. The movement to personal communications technology throughout the world could mimic the successful usage of cellular telephones, as the only means of effective communications, during the San Francisco earthquake.

One measure of the world's concern and its search for solutions has been through the establishment of the "International Decade for Natural Disaster Reduction."[1] Various high level councils and advisory committees, the UN and its agencies, the intergovernmental, nongovernmental and private voluntary organizations are meeting regularly to seek new and better ways to deal with disaster. The need to find new technologies which can survive both the forces of nature unleashed or those disasters assisted or produced by man-made means is paramount.

The concept of personal communications units distributed widely by satellite again surfaces as a technological solution. Currently these units only exist in limited regions of the world. Cellular expansion, dependent on terrestrial distribution, will be slow to reach parts of the world that are so often devastated by disaster.

The demand for information: more, better, accurate, reliable, timely, available and affordable, arises time and again in the deliberations of the UN and other agencies concerned with disaster communications. Various telecommunications systems have been examined: most existing systems are subject to vulnerabilities of size, survivability, affordability, portability and ease of use in a disaster situation; some require external power sources; some are too large to be quickly put in place; some need time-consuming governmental approval to be deployed and, in most instances in the developing world, they are too expensive to be stockpiled where they are most apt to be needed.

The Declaration of Tampere

An international group of experts in communications and disaster management, including key leaders from within the United Nations system, met for a global Conference on Disaster Communications in Tampere, Finland, in May of 1991. The Conference issued "The Tampere Declaration on Disaster Communications."[2] Among the major recommendations of that Declaration, which has been distributed throughout the UN system and to governments, intergovernmental organizations and nongovernmental organizations, worldwide, were:

> "...There is an urgent need to improve international cooperation in communications and enhance national communications capabilities in order to reduce loss of life, damage to property and livelihoods, and damage to

---

[1]Resolution adopted by the General Assembly, A/RES/44/236, 20 March, 1990.

[2] The "Declaration of Tampere," produced by the Conference on Disaster Communications, Tampere, Finland, May 20-22, 1991. Convened by the United Nations Disaster Relief Organization (UNDRO), the International Telecommunications Union (ITU) and the International Institute of Communications (IIC).

the environment caused by disasters.

> "...The Tampere Conference stresses that improved flows of international information through telecommunication technologies, including satellite and broadcasting, can assist in the prediction, monitoring and early warning necessary to prevent some of the consequences and reduce the impact of such disasters once they have occurred. There is an urgent need to improve the nature, scope and quality of information being transmitted internationally, including its validity, significance, accuracy and timeliness."

Universal Network Access: The Future Technology

For years there have been dreams of a worldwide "personal communicator;" a highly portable, easily transportable, battery and/or solar-powered universal network access system; a device capable of connecting anyone, anywhere with anyone, anywhere.

There is one technology, close at hand, which meets the need. IRIDIUM, developed by Motorola, is a satellite-based communication system which can provide personal communications to meet the needs of the disaster assistance community. The system will provide handheld, pocket-size, subscriber units, for communications anywhere, at anytime and will be of special value for use in regions lacking standard or reliable telephone services, whether those services simply do not exist at all or whether conventional services have been rendered inoperative because of a disaster. The IRIDIUM system is scheduled to initiate service in 1996, with full operation planned for 1997.

The IRIDIUM System

The two critical elements of the IRIDIUM system are the space segment: a satellite constellation of 77 low-earth orbit satellites in seven different polar orbits, and the IRIDIUM user terminals which provide: two-way voice, data, facsimile, RadioDetermination Satellite Service (RDSS) positioning and location, and paging. These terminals are handheld and resemble ordinary telephones, similar to those in the now familiar cellular telephone systems. They are lightweight and battery-powered. For IRIDIUM, or any universal system to succeed, however, countries worldwide must agree on spectrum allocations for its use, to ensure that anyone anywhere in the world can reach anyone else in the world simply by dialing direct.

During the Loma Prieta earthquake in California, virtually all of the disaster-relief agencies noted that the disaster-assistance and relief effort was held together by cellular telephony.[3] The highly developed, fixed communications infrastructure did

---

[3] "A Review of the Effectiveness of Communications During and Shortly After the Loma Prieta, California Earthquake."

not perform adequately. A system capable of providing global network access could easily tie into those cellular systems that survive the catastrophe as well as operate on its own, from handheld communicator to handheld communicator. It is anticipated that the IRIDIUM telephones will be in the hands of many private and institutional users worldwide. Additional units should be stockpiled by those charged with disaster relief and assistance, such as, in the developing countries, the United Nations Development Program's resident representatives.

The World Administrative Radio Conference

Industry recognizes the technology is available today, but there are challenges to make it come to fruition. If an IRIDIUM-like system is to achieve its full potential, action must be taken at a World Administrative Radio Conference (WARC) scheduled to take place, under the auspices of the International Telecommunication Union (a UN Agency) from the 3rd of February to the 3rd of March, 1992. A WARC allocates worldwide frequencies through a process of negotiation amongst all member countries of the ITU, a one country/one vote body.

Nations have the opportunity to choose. Does an IRIDIUM-like system represent the best use of these scarce frequencies? If decision-makers agree, they can influence their national governments' telecommunications policies and petition for telecommunications services that can serve the disaster community.

The timing is perfect. The International Decade for Natural Disaster Reduction mandates the use of technology for disaster relief. The technology is waiting, but it's not going to be easy: there is general agreement that the challenges are political, not technical. Will the countries represented at the WARC make the commitment to telecommunications technology that offers such great promise to disaster relief? Can the world wait for the next WARC to bring the issue of disaster communications to the negotiating table? Can the world afford to prolong human suffering?

The Experts' View

The community of disaster communications experts has made its needs clear. It did so as far back as 1979,[4] and as recent as at Tampere and other conferences.[5] [6]

Now, it must press its case at other international venues. Disaster respects no national boundaries; it can strike anyone, anywhere, and at any time. Advanced communications technology may not prevent disasters, but can minimize the tyranny disasters impose upon the peoples of the world.

CONCURRENT RAINFALL RATE, BEACON AND TV CHANNEL ATTENUATION, AND SKY NOISE TEMPERATURE MEASUREMENTS IN PAPUA NEW GUINEA.

G.H. Bryant, L.L. Watai and R. Tia,Jnr

Department of Electrical and Communication Engineering ,The Papua New Guinea University of Technology

Lae, Papua New Guinea

1. ABSTRACT

A low cost, less complex system for measurement of propagation path attenuation of satellite signals in the Ku-band using standard equipment is reported. Propagation attenuation on AUSSAT beacon and TV channel 14 BMAC signals is measured against sky noise temperature and rainfall rate. The low level beacon at 12.74975 GHz carries PCM data on a phase modulated carrier with a peak deviation of 32KHz. The carrier remains constant for long periods but at unpredictable times during telemetry activities, the levels change. A second method designed to avoid this problem is used where the carrier is extracted from the FM BMAC signal on channel 14 which carries the Australian ABC television service at 12.629GHz. The third approach involves using a Ku-band radiometer to measure directly the expected transmission losses from the satellite by monitoring the sky noise temperature. This paper describes the experimental arrangement and presents some of the results obtained to date.

2. INTRODUCTION

Rain in the lower atmosphere is one of the major causes of signal loss on satellite transmission. Considerable work has been carried out in analysing this problem in the temperate regions (1). The CCIR and other slant-path propagation prediction models are well tested against temperate data accumulated over many years. In tropical regions, investigations have been much more limited. Based on only scant experimental data, there is some evidence these propagation models are not sufficiently accurate for regions of severe rainfall rates such as the tropics. In order to evaluate the theories and model-revisions that attempt to take account of tropical regions, it is necessary to have measurements from such regions. In recent years, a few tropical experiments (2) at Ku-band have been designed mostly using radiometers but also in some cases with beacon monitoring from a suitable satellite. However, this is one of only two experiments of this kind in existence in this region of the Pacific (2). Measurement data from this project will help rectify this data gap and provide results against which to test any propagation model proposed for the tropical regions.

It is desirable to make measurements in a range of elevation angles because the significant differences between tropical and temperate conditions relate to the size and number of individual raincells (3). For instance, at near vertical incidences during intense tropical rain, the entire beam may be filled by one raincell, giving maximum attenuation (1). However, beams at low elevation angles may pass through a number of cells, but because the horizontal extend of a cell is relatively small (1,4), it would be only partially filled, resulting in less signal attenuation.

It may not always be possible to choose a satellite with the preferred elevation angles, especially when other factors, such as a suitable beacon carrier frequency and EIRP are to be considered. It therefore becomes important, if the amount of tropical data available is to be increased rapidly for further Pacific installation that use should be made of satellites with less ideal signal formats, such as television or data carriers. This has been the approach at Lae in Papua New Guinea.

A second aspect of this kind of experimentation is that in many Pacific countries, there is a need to minimise costs and to avoid complexity. By using standard equipment where possible, by careful conditioning of the data before storing, through the use of well tried and popular software such as the Lotus spreadsheet, it is possible to meet these challenges.

This paper describes the design of the experiment,gives an outline of the spreadsheet software and presents results to date. It is hoped that the relative simplicity of the instrumentation and the minimal software development will encourage others to join in the gathering of this vital data on tropical propagation.

3. SYSTEM DESCRIPTION

Located 7 degrees South and 147 degrees East, Lae is classified as between the M and P zones (5) on the CCIR rain climatic regional map. The AUSSAT satellite is at 161 degrees East. The elevation angle from Lae to AUSSAT is 73 degrees. So far this is the highest elevation angle anywhere in the world. The monitoring station is looking almost straight up at the satellite and any rain affecting transmission will be directly overhead.

The satellite is not beamed directly at PNG and it's full strength received level is quite low. In order to achieve the highest possible signal to noise ratio two different techniques are used to measure the down link attenuation. The first method uses a beacon carrier in a bandwidth of 300Hz. The other uses the TV carrier in a bandwidth of 300KHz. These carriers have EIRPs of 0dBW and 31dBW, with corresponding C/N of 26.6dB and 27.6dB respectively. The methods are scalar in nature with no phase lock requirements so that the detection thresholds are effectively at the noise level.

In the first technique, the beacon signal is measured. It is much lower in level than the TV signal and requires very narrow band filtering in order to detect it at all. The beacon carries telemetry, selectable in four modes by ground control. In normal operation the common mode beacon frequency of 12.74975GHz is selected for continuous teleme-

try. This results in a constant carrier level when measured over all attainable integration times and allows the use of a narrow band filter (300Hz) to minimise noise. The nominal beacon received frequency has a regular +/- 30KHz variation and it's level is approximately 30dB down on that of the unmodulated video carrier. It is required to measure fades of up to 15dB and therefore a signal to noise ratio of at least this figure is necessary. In practice, a dynamic range of 20dB has been achieved. To achieve the required 20dB, the total sweep is no more than 10KHz, the spectrum analyser IF bandwidth 300Hz and the video bandwidth less than 10Hz. If the carrier varies due to modulation mode switching, it becomes necessary to extend the bandwidth to at least 100KHz to include the sidebands centred at +/- 32KHz. That would reduce the C/N power ratio at Lae to 1.37dB, against the minimum acceptable range of 10dB (by the Contractor, INTELSAT).

To measure the beacon carrier in a 300Hz bandwidth, the filter must track its frequency drift which is as much as 15KHz an hour due to local oscillator drift in the LNC. The commom mode beacon at the LNC output also shows a diurnal drift of about 0.5MHz. A Tektronic 2710 tracking spectrum analyser with a sweep time of 30 seconds holds the response of the drifting signal at the screen centre and updates the peak reading every sweep. During a deep fade when C/N is 0dB, the tracking assumes an "idle" mode and will resume tracking when the signal returns, provided the response has not in the meantime drifted off the screen. Fades are unlikely to exceed 10 minutes and since a one hour drift is almost 15KHz, tracking will be recovered even in worst fading, provided the sweep scan is about 10KHz. In practice it was found that during a storm the drift rate increases and tracking loss can occur. The analyser has a video output comprising a voltage which is proportional to the peak vertical deflection of the trace. This voltage, which is proportional to a reference level in dBm, is the one converted by the interface A/D in the BBC-B microcomputer.

Beacon measurement provides a reliable method of monitoring downlink attenuation, but there is always a possibility that carrier level may change due to modulation schedules. For this reason, and to increase reliability through redundancy, the second method of carrier detection in the TV channel runs concurrently with direct beacon measurements.

The second method involves monitoring the FM BMAC TV signal on channel 14 which carries the Australian ABCTV service at 12.629GHz. Because of the very low signal strength, detection thresholds, in the full FM bandwidth of 25MHz, are effectively at noise level. To reduce the effects of noise on the signal, measurements can be done only in a narrower bandwidth. To achieve this it must be certain that the signal will remain within the measurement channel while measurements are made. Tests on the BMAC signal have revealed that by making measurements only during a precise time interval of the frame synchronization period, the noise can be limited by filtering and yet be certain that there is a full power signal within the measured bandwidth. It was found that it is possible to recover accurately the peak pulse levels in an IF bandwidth of 300KHz. A Takada Riken spectrum analyser with a sweep time of 10 seconds is used to monitor continuously the TV signal strength in a narrow (300KHz) channel. At least one sample is taken per sweep. During the frame synchronization period, pulses of full power carrier level are detected and stored in a peak hold detector. This detector is updated every 10 seconds during the sweep. The output of the peak hold circuit is a DC level directly proportional to the received signal strength.

A third aspect of the experiment involves using a 11.6GHz COMSAT radiometer from INTELSAT under Contract INTEL-870, which directly measures the expected transmission losses from the satellite by monitoring the sky noise temperature. It is used as a backup and provides clear sky reference. Antenna temperature is sampled at the same rate as the beacon and TV channel to a resolution of 4 degrees Kelvin.

Propagation attenuation of the satellite beacon and TV signals is measured against rainfall rate and sky noise temperature.

The arrangement of the complete monitoring station is shown in Figure 1. The attenuation on the down link is monitored in 1dB intervals directly from the beacon and TV channel 14. As mentioned both the TV channel and beacon depend on conventional spectrum analysers with sweep times of 10 and 30 seconds respectively. The lower beacon rate is to reduce the amount of data collected whilst providing a level of backup redundancy against a channel breakdown or up link event. Two tipping bucket raingauges are used to measure rainfall rate. The gauges agree to within 5%. Pluviometer rainfall total for each month is compared with the accumulated recording of the bucket tips for the same month. They agree to within 6% but accuracy up to 10% is acceptable at high rainfall rates. No calibration correction has been done to the gauges because the maximum rainfall rate is about 200mm/hr which is their maximum rate of operation. Also, under the contract, INTELSAT requires 180mm/hr as the maximum in this work.

Data collection is done with a BBC-B microcomputer that has four resident A/D converters, an 8-bit parallel I/O port, and an RS432 serial interface to an IBM AT. The configuration and monitored ranges are as follows:

Beacon.....Clear sky (0dB) to -20dB, in 1dB steps: A/D 1.
Channel 14.....Clear sky (0dB) to -20dB, in 1dB steps: A/D 2.
Radiometer.....0 to 395K in 4K steps: (BCD) 8-bit USER port.
Raingauge 1.....0.5mm equivalent rainfall per tip: Port PB0.
Raingauge 2.....0.5mm equivalent rainfall per tip: Port PB1.

4. SOFTWARE

Simply making the measurements is only part of the experiment. The results of all three measurements, and the rainfall rate must be continually monitored and recorded. Computer software was specially developed to log all these measurements 24 hours a day and seven days a week. Under normal running conditions with no rain, a record is taken every 10 minutes with power and temperature levels compared to a 5 minute running average. (The 5 minute running average is done to reduce the data volume). If rain is detected through the tipping of a gauge or one of the power readings becomes different from the running average of power ratio by 1dB or more, the program automatically records the measurements every 10 seconds. The 10 second

sampling is usually considered the maximum for adequate event capture rate. It will continue recording at 10 second intervals until the reading becomes equal to the running average. Then it resumes recording every 10 minutes. A similar 5 minute running average on the radiometer output ensures that for a departure of 4 K from the average, recordings of all measurands revert to 10 second intervals.

Once data is collected by the logging computer, a further programme has been developed which transfers the data to an IBM AT for data processing and analysis using the LOTUS package.

5. RESULTS

5.1 10 Minute Data

Figure 2 shows an example of processed 10 minutes data. The 10 minute Beacon and TV Channel levels show a diurnal variation of the oder of +/- 1dB and this is superimposed on a longer term drift of 7-8 days. These results have been found by deleting all data from the record except that at the 10 minute intervals. A running average over 24 hours is then obtained and the 10 minute variations plotted relative to that. The effects of rain on the 10 minute data has been eliminated by replacing "rain damaged" 10 minute data with 10 minute data from the nearest quiet zone at the same time of day, e.g. 24 hours earlier. The 10 minute levels are then used as the zero reference for the calculation of event attenuations. This procedure is based on the assumption that the major part of those variations is due to satellite movement. Lae is at the edge of the beam pattern and the small daily satellite movements varies the strength of the signal monitored by a large amount due to the distance involved. The clear sky which is taken as reference is related to the 10 minute data. (However the true reference is obtained by adding the 10 minute and long term variation and then comparing with the radiometer. This is because the radiometer is the final check.)

There is sometimes a discontinuity in the 24 hour running average from week to week because the averaging in each block begins 12 hours into the data and ends 12 hours before the end. The first and last 12 hours appear constant on the longer term drift in Figure 2 because they are set equal to the start and finish average values respectively.

Most of the fluctuation details on the diurnal patterns are due to small rain cells occurring high up in the beam. The main problem here is that the beacon and the TV channel are always showing rain. Clear sky can not be seen and therefore establishing a reference becomes difficult. To overcome this, the radiometer data is used. The radiometer sky noise temperature measurement results are used to calculate the sky attenuation for attenuations less than 1.5dB. During an event the attenuation is greater than 1.5dB and clear sky reference is given by a linear interpolation between the -1.5dB levels at the edges of the event. The +/- 1.5dB is chosen because the diurnal variation is of the order of +/- 1.5dB and the small raincells high up in the beam, about +/- 1dB.

Figure 3 is another example which shows data recorded during the period of 3/3/91-10/3/91. It shows rain showers during the whole period. The longer term variations can also be observed.

5.2 Attenuation And Rainfall Exceedence

The event data is taken at 10 second intervals or at the rate of bucket tips. Otherwise under normal running conditions with no rain, a record is taken every 10 minutes, with signal and temperature levels compared to a 5 minute running average. If rain is detected or one of the results changes in level by 1dB or more, automatically, all parameters are recorded at 10 second intervals until the current reading equals the running average. This ensures that any fade greater than 1dB causes recordings at 10 second intervals.

Attenuation on the Beacon and TV Channel is derived by the difference from clear sky signal level and that during a rain event. For the radiometer, attenuation is obtained from the difference between the clear sky noise temperature and that during a rain event. Rain rate is found from the time between bucket tips. Figures 4 and 5 shows examples of monthly cumulative statistics on rainfall rate, beacon and TV channel attenuation calculated from the measurement data of February and March 1991. Attenuation and rainfall rate exceedence statistics for 9 months (Feb.-Oct.,1991) have been computed to date. These have been averaged for preliminary comparision with the 1 year CCIR model. This is done in Figure 6.

The raingauges agree well up to 135mm/hr. This is because gauge1 is adjusted for highest accuracy at low rainfall rates and gauge2 is most accurate at high rainfall rates. However, in practice, gauge2 is most reliable. Therefore the monthly rainfall rate data from gauge2 was used to compute the 9 month average rainfall rate exceedences statistic in Figure 6(b).

For attenuation exceedences, the TV channel is the most reliable because it is based on 10 second sampling on the spectrum analyser whereas the bandwidth limitations limit the beacon sampling to 30 second intervals. Therefore the 9 month average attenuation statistic in Figure 6(a) was obtained from the monthly TV Channel attenuation exceedences.

6. DISCUSSIONS

6.1 Event Data

The high angle of elevation ensure that most events cause the whole beam to be filled with rain. This is illustrated by Figure 7 which shows the TV Channel and rainfall rate. (The rain figures need to be multiplied by 10). The event in Figure 7 was recorded during stratiform rain conditions. It is interesting to note the degree of correlation in the fine details of the rainfall rate and TV Channel attenuation, and the overall coincidence of the patterns in these stratiform conditions as illustrated in Figure 7(b). This is an expanded section of the first part of Figure 7(a). The incidences of such coincidences is high at all times during "wet" stratiform conditions. Results to date do show the tendency for high rainfall and high attenuation to occur more frequently at night-time, whereas during the day time the tendency is for lighter rain and lower attenuation.

Figure 8 shows a typical example of convective "dry" season conditions. The nature of the rain is no longer stratiform and coincidence of attenuation and rainfall occurs only at the peaks. There are periods when rainfall occurs with no measured attenuation. This would prove that rain moves in columns. The rain gauges can therefore collect rain whilst most of the beam is free of rain. Alternatively, attenuation, usually low, will occur during periods when the rain gauges do not register. For part of the year, rain columns move from north to south across a beam that looks more or less north east. In PNG, it is possible to be in rain on one side of the road whilst the other side remains perfectly dry. It is therefore quite possible that most of the beam could be filled with rain whilst the raingauges collect no water.

6.2 Comparison of Exceedences with CCIR Model

When looking at Figure 6(a) it should be remembered the CCIR model gives good agreement with results from attenuation measurements taken over periods in excess of two years (7) whereas the data here refers to a period of only 9 months. The two model calculations use different slant path reduction factors. The improved model takes account of the effects of the high rainfall rate in the measurements (7) and shows good agreement with the measured results.

For rain rate exceedences, the measurements are compared with the CCIR regions M, N and P. None of these regional models gives good agreement with the measured results. There is a marked break in the slope at $R_{0.01}$, the rain intensity exceeded for 0.01 percent of the time. Again care must be exercised because $R_{0.01}$ refers to an average year and this is only a 9 month period. The break at $R_{0.01}$ has been found at other tropical sites and some coastal areas where large expanses of water or mountains are found (8). Lae is situated close to the sea and is surrounded by mountain ranges with heights up to 3,000-4,000 metres. Moupfouma has given an atlas of u values in a model for rainfall rate given by (8):

$$P(R \geq r) = \frac{a.\exp(-ur)}{r^b}$$

where $P(R \geq r)$ is the probability of the rain rate r exceeding any rain rate R and the constants a, b are found from the measured or estimated value of $R_{0.01}$.

Moupfouma states that higher values of u are sometimes required for $r > R_{0.01}$ and that these conditions are associated with mainly stratiform rainfall. In contrast, Lae has highly convective rainfall with rain column diameters considerably less than 4 km. The high elevation angle to the AUSSAT beacon has allowed single rain columns to be clearly distinguished. With $u = 0.35$ or 0.55 for rain exceedences less than or greater than $R_{0.01}$ respectively, the experimental results show good agreement with the Moupfouma model. The high rainfall rates, in excess of 150 mm/hr are not statistically significant, because there is only one event at 170mm/hr and at 200mm/hr respectively. This is evident by the horizontal line of exceedences in each case. As more data is collected, it is assumed that their mean level will approach the u_x curve. A second factor is that the tipping bucket rain gauges read about 10 percent low at the high rainfall rates. These considerations have been taken into account by adjusting the u_x curve to the upper rainfall limit of each event as represented by a horizontal line of data points.

The results of early propagation work at Lae have been reported by Harris and Milner (5). Average annual and worst monthly cumulative distribution of rain intensity were derived from pluviometer results collected over the period 1983-86. The annual average rainfall intensity distribution is shown in Figure 9 with the CCIR model and classification zones M and P. Some preliminary comparisons can be made with the Harris/Milner curve and that of Figure 6(b) which was obtained from this work. Although the curve in Figure 6(b) was calculated from only 9 months of data, it can be observed that there is agreement between the two curves for rain rates up to 90mm/hr. Above 90mm/hr the Harris/Milner curve drops off due to the limitations of their method (5). The curve in Figure 6(b) goes well up to 200mm/hr. However, as mentioned earlier, the high rainfall rates in axcess of 150 mm/hr are statistically insignificant. When the full year data becomes available, it is expected that Figure 6(b) will be refined and made more accurate.

7. CONCLUSION

An overview of the experimental work being carried out at Lae, Papua New Guinea, under Contract, INTEL-870, has been given together with results gathered over a period of 9 months. Until data from a full year of measurement becomes available, no substantive conclusions can be drawn from these results. However, the preliminary results do comfirm the findings of Harris and Milner which showed that PNG is between M and P zones on the CCIR rain climatic regional map.

The effect of tropical rainfall on signal propagation above 10GHz has been clearly demonstrated with preliminary attenuation figures from the beacon and TV receivers and radiometer.

The system and techniques described are not complex and could be reproduced anywhere. Standard equipment and well tried software are used to minimise cost. It is hoped that the relative simplicity of the instrumentation and the minimal software development will encourage others, especially in the Pacific, to join in the gathering of this vital data on tropical propagation.

WARCs AND FUTURE ISSUES

R.E. Butler

WORLD ADMINISTRATIVE RADIO CONFERENCE (WARC) 92

WARC 92 is the first conference for a general review of parts of the Radio Frequency Table (Article 8) of the Treaty Force Radio Regulations appended to the International Telecommunication Convention since the very general World Administrative Radio Conference (WARC) 1979. Within the competence of its agenda, each WARC establishes a revised framework for internaitonal and national arrangements for the planning and use of the spectrum.

In brief, WARCs provide the basis of supreme tests of international co-operation. In particular, they provided the necessary recognition to enable industry, system designers, planners, manufacturers and service innovators to proceed with confidence towards cost effective production, service adaptation, innovation, investment and operation, along with the necessary user qualify. These assume particular importance in the current era of globalisation, the search for world-wide compatability, the most effective investment and efficient use of the spectrum, servicing adequately the interests of all nations.

The 1980s saw an unprecedented and intense conference programme initiated from the last general review of the radio spectrum and allocation table at WARC 79. Then the accent was not merely on technology developments since the preceding comparable conference of 1959, but also on the issues of equitable and appropriate, equal access, taking account of the relevant provisions of the International Telecommunication Convention and ever increasing service and policy needs. Thus, WARC 79 led to a whole series of specialised service conferences to open up, plan and use more effectively additional radio spectrum for particular service objectives, albeit for fixed, mobile, broadcasting including HF (shortwave) broadcasting and a variety of satellite services.

Those conferences of the 1980s completed their tasks with varying degrees of success, and some limitations became evident. They left unresolved accommodations of a number of service needs like, for example, for public correspondence to aircraft as well as appropriate spectrum to permit the proper evolution of a variety of mobile service needs and advanced quality video services. Then, too, there has been the need to review the technical and other aspects to permit the rational evolution of satellite sound (audio) broadcasting which was also raised initially at the WARC 79, but which for both technical and other reasons in the climate of the decade, has not been settled.

The last of such service conferences which prompted the need for WARC 92 was in 1988.

Since then technology, opportunities, service needs and the telecommunication environment have been advancing and changing rapidly.

Digitalisation is also bringing significant quality improvements, greater band widths, enhanced reliability and stability for low powered and low cost service applications with growing service convergence between wireless (radio) and wired systems. All of these developments can bring unprecedented possibilities of portability, mobility and personal user convenience. They bring opportunities for multi-purpose use of spectrum and faciliites, albeit for satellite or terrestrial operations.

Thus, we have the opportunity to enter into the era of tetherless communications in which handsets, stations, terminals and a host of new communication systems and devices can be linked together by wireless means (terrestrial and space) bringing comparable quality but greater flexibility than conventional wired connetivity of the past. The traditional dependence upon wired connectivity is being radically reduced. Choice, flexibility and appropriate cost alternatives through wireless connectivity are not only feasible, but also realities, both in local loops and in regional and global two-way interactive communications.

Personal communication networks (PCN) technology has also arrived. It necessitates the appropriate spectrum for both terrestrial and satellite means - the latter, in particular, through the advent of low earth orbitting satellites (LEOs) in which the conference has the obligation to establish the necessary basic spectrum parameters to permit the realisation of appropriate service design, system engineering, production and adaptation to enable investment and the like to proceed confidently. Of course, the use of LEOs for particular purposes has been tried during the decade and, like most space applications, used for other government/experimental means. There comes a time when adaptation should proceed for general service applications. The time is ripe for the recognition of such systems, knowing that they would operate with simple hand-held units/terminals/handsets where related to:

- either slow bit rate data transmission and collection, with telemetry (very important for future environmental mangement needs), or

- more up-market solutions with composite voice and data systems providing access-type possibilities to and between public and private networks.

The 1988 World Administrative Telegraph and Telephone Conference (WATTC), Melbourne was a landmark in establishing the first set of integrated internaitonal telecommunication regulations for integrated international telecommunication service and networks through the introduction of the necessary framework provisions (in contrast to detailed service regulations). It provided the foundation for implementing the "networks of the 90s" and beyond.

WARC 92 can well be the 1990's watershed for the future of the ITU in the radio spectrum sector, providing a major test of the Union's flexibility to meet on a global basis service needs, permitting more appropriate sharing and use of the spectrum, resources, the emerging service opportunities and innovative technology opportunities.

In today's globalisation, decisions must be taken with a world-wide application perspective. Many realise the significance of the importance of economies of scale, technology transfer and the avoidance of technical interference with current and planned uses of the spectrum in the long term perspective. We need to maximise the opportunity of portability and mobility, which now extend well beyond national borders and, indeed, regions. These are the important and growing prerequisites for achieving efficiency and seemless interactive connectivity with appropriate access with wired systems and networks, private an dpublic, on a multi-country basis, subject to the respect of national sovereignty and the like.

Thus, at WARC 92 there is the responsibility: not merely to review the results of previous conferences and the particular issues needing more spectrum or improvement in the effective use of the spectrum, albeit as examples for mobile or HF (shortwave) broadcasting services; but also accent in the decisions for more efficient use of the spectrum which necessitates a departure from traditional separations and would lead also to more efficient deployment of investment and the like. Some services have already been able to achieve much towards such objectives, as in the case of single side-band technology, digitalisation or improved planning arrangements in order to absorb certain of the expanded service demand sover the decade.

There is the need to provide the frameworks for the future, both in regard to emerging service growth and for global allocations like, for example, the variety of possibilities, including earth orbitting satellites (LEOs) because of the unprecedented opportunity they provide for access services to complement or integrate with both mobile and fixed service networks, including in the areas which are unreachable at present by the classical fixed/mobile cellular-type networks, etc.

Then too, in the case of audio satellite broadcasting, it will be important to realise the significance of the new quality transmission possibilities and, in some cases, the appropriate opportunities for many countries to leap frog traditional technology applications and to ensure nationwide quality service. The evolution of this technology application necessitates a more flexible approach to the planning and access to the geostationary orbit/spectrum than the existing radio regulatory provisions for the broadcasting satellite

service. On the other hand, it is important that the arrangements for the introduction of such a service do not bring the same difficulties as has occurred in certain other broadcasting services like HF (shortwave) broadcasting services over four decades or more.

Whilst the WARC 92 is not yet considering specific spectrum allocation for the growing extension of local area networks (LANS) using wireless technology, it is likely that portability will lead to the need for certain harmonisation of spectrum use for such purposes. They offer tremendous economic and social opportunities and trade-offs across the board from the campus and the classroom to the home and the workplace. Some identification of the emerging national applications of spectrum use for LANS with existing service bands will be useful.

All of these developments and enhancements are with us. How we enable their effective application and widespread availability through the ITU frameworks with benefits to all communities will depend on the visionary inputs and related co-operation for the long term perspectives to the preparations and decision making at WARC 92.

COMMUNICATIONS SATELLITES FOR THE PACIFIC ISLANDS

William Cooperman
Dennis Connors
Charles Franz

Abstract

The paper identifies twenty-nine current or proposed telecommunications satellite systems that have the potential of providing services for the Pacific region. Eighteen geostationary satellite systems and eleven non-geostationary systems are described and systems that may be relevant to telecommunications needs of the Pacific islands are noted.

Communications Satellites For The Pacific Islands

INTRODUCTION

The Pacific island nations have long recognized the benefits that an efficient communications system could have on the economic and cultural well being of the region. Many studies and surveys have examined the potential for advancement of communications within the Pacific island nations. Especially relevant to the Pacific has been the advancement of satellite technology. With the vast amount of space between islands in the region and the general low density of population, satellite communications has been recognized as one of the most reliable and efficient technologies. Other prevalent technologies such as High Frequency radio (HF) serve a very useful function for the region. HF radio systems, however, have severe limitations concerning both reliability of service and the variety of services that can be offered.

INTELSAT, INMARSAT and PEACESAT have been three principal providers of satellite services for the Pacific island nations. These geostationary satellite systems have been able to offer full-disk footprints for the vast majority of the island nations and have provided services that have connected remote island communities to the rest of the world. Other providers such as AUSSAT and OTC International have been able to offer regional signals that provide useful services to island nations within the specific coverage patterns of their respective satellites.

Although satellites have been providing useful services for almost thirty years, the technology is far from stagnant. Recent advances will make possible the introduction of services that could only have been dreamed of just a generation ago. The Pacific islands may be able to take advantage of these new technologies in the next few years. Services such as rapid data transfers, inexpensive earth terminals and portable hand-held telephones are possible by the end of the decade. It is recognized that the ultimate cost of these services and the desires of the Pacific islanders to participate in the new services will be key to the adoption of advanced communications services; but a great potential exists in the near future.

The intent of this paper is to review current and proposed satellites that cover the Pacific island region. Each satellite has advantages and disadvantages depending on the specific needs of the user. Cost may be a factor in some proposals, coverage may be an issue in another proposal, and lack of a particular service may hinder the adoption of a particular satellite system. Some of the proposals could offer significant advantages such as economical infrastructures, availability of new services and cross-cultural or cross-island connections that are not now possible. It will be up to users to decide which service best fulfills their specific needs.

1035

The staff at NTIA decided that they needed to review all satellite systems that are either currently deployed or that are proposed for service to the Pacific to determine the feasibility of providing a long-term solution for PEACESAT. The purpose of this paper is to provide an overview of the current potential for satellite telecommunications in the Pacific without analyzing specific service needs. It is recognized that the Pacific islanders have various communications needs and that no one technology or satellite system can serve all those needs. It is also recognized that a combination of technology including high-frequency radio transmissions (short-wave), undersea cables[1], ground-based telephony service, large-scale telephony satellite services, and thin-route low-cost satellite systems are all appropriate for various uses in the Pacific island region.

Satellite Study

A detailed review of commercial satellite activity concluded that there are twenty-nine proposed satellite systems which could provide service to the Pacific region. These proposals include both geostationary and non-geostationary systems. However, the vast majority of the satellites currently in existence or proposed for the future, do not focus on the needs of the Pacific islands *per se*. While the Pacific islands may be within the footprint of a proposed satellite system, the main focus of service is usually on those nations along the Pacific Rim which are highly industrialized or which have very large populations. The vast spaces across the Pacific islands and the general sparsity of population do not usually make the Pacific islands an economic attraction to many telecommunications satellite system service providers.

This paper reviews each of the 29 current and proposed satellite systems which have the potential to serve the Pacific region. Information for this study has been obtained either directly from the system sponsors, through official filings at the U.S. Federal Communications Commission (FCC) or at the International Frequency Registration Board (IFRB) of the International Telecommunication Union.[2]

The review is divided into four sections:

Section A	An overview of projects using geostationary satellites.
Section B	An overview of systems that propose to use non-geostationary satellites employing low-earth orbits, high orbits or highly elliptical-orbits.
Section C	Detailed descriptions of eighteen geostationary satellite systems.
Section D	Detailed descriptions of eleven systems that have been proposed using low-earth, high or high elliptical-orbit satellites.

1033

SECTION A

Overview of Geostationary Satellite Projects

Geostationary satellites reviewed are located above the equator between 150° West longitude and 140° East longitude and have the potential to provide service to all the major Pacific island communities.[4] Satellites located within this arc can be viewed by earth terminals from anywhere in the Pacific islands. The satellites located directly east of this arc are domestic satellites serving the United States. West of this arc are satellites providing, or planning to provide, domestic or regional service to the Asian countries. These satellite systems, including ASIASAT, PALAPA, CHINASAT, INSAT, and the proposed THAISAT, KOREASAT and MEASAT systems, are located too far west to provide service to the Pacific Island Nations but are more fully described in the appendix.

INTELSAT is an international telecommunications satellite consortium that has the mission to provide worldwide service including the Pacific Ocean region. Through the use of global footprint pattern satellites, INTELSAT is able to provide coverage for the Pacific islands. Unfortunately, satellite technology needed to produce a global footprint required the use of very large and expensive earth stations. INTELSAT service has been valuable in providing worldwide coverage and coverage has become widespread. INTELSAT, however, has a stated policy that all users will pay fair market prices for services. Due to the relatively low economic activity in the Pacific islands, this policy does not allow many of the Pacific island nations to acquire more than one earth terminal for each country. The outer islands are limited to other communications technologies such as HF radio which do not have the same capacity, capability or reliability as satellite communications. INTELSAT is planning to assist the Pacific islands in the future with the launch of two INTELSAT VII series satellites over the Pacific in 1993 and 1994. The new satellites are designed to provide more signal power which will allow for much smaller and more affordable earth terminals. The support of very small aperture satellite (VSAT) technology by INTELSAT VII satellites should encourage the island communities to acquire more earth terminals for expanded telecommunications.

Another major provider of satellite services for the Pacific Ocean region has been the INMARSAT Organization. The INMARSAT system carries ship-to-shore and ship-to-ship services for the maritime community. Recently, however, the Organization adopted policies allowing it to provide mobile service to land-based individuals, including those in the Pacific. For instance, INMARSAT has made a specific commitment to the 70 residents of Pitcairn Island to provide telephone-like service to that island. INMARSAT, through its recently announced Project 21, is considering other low-cost mobile services, but it is not clear at this time what the availability

1036

The other four satellite services currently offered in the Pacific region are: AUSSAT A-3, COLUMBIA-TDRSS, STATSIONAR, and PACT. The AUSSAT A-3 satellite provides a footprint to the South Pacific and covers the Solomon islands, Fiji, Tonga, America Samoa, Western Samoa, Vanuatu, New Caledonia, the Cook Islands, Tuvalu and Nauru. Services provided include television, single-carrier-per-channel (SCPC) voice channels and data. The South Pacific service on the AUSSAT A-3 satellite is operating at full capacity and no further space is available. The COLUMBIA-TDRSS is a new satellite intended to provide coverage to the North Pacific and will offer voice, data, and video. COLUMBIA-TDRSS is not intended at this time to be connected to the Public Switched Telephone Network (PSTN). The STATSIONAR system consists of Russian satellites that include global coverage beams. Due to the political environment in the former Soviet Union, the current status of STATSIONAR service in the Pacific region is unknown. The last satellite system currently providing service is the Pacific Area Cooperative Telecommunications (PACT) system which is operated by OTC International and uses capacity on an INTELSAT satellite. PACT provides voice, facsimile and in-band data services to the Cook Islands, Nauru, Niue, Marshall Islands, Tuvalu, and Kiribati.

Our review also found 11 proposed geostationary satellite systems. Some of these satellite proposals call for more than one satellite in orbit. The following satellites propose voice, data and video services: ASIA-PACIFIC, PACSTAR, PACIFICOM, PANAMSAT, TONGASAT, and UNICOM. ASIASPACE is proposing a global coverage pattern for direct audio broadcasting. SAT/TRACS is proposing a global footprint for data, positioning and short messages. COLUMBIASAT is proposing a satellite where both the footprint and services are to be determined. FINANSAT has proposed transmitting primarily digital data among the United States, Asia and Australia. The Russian EXPRESS satellites will have a global footprint, but has not specified services.[5]

Eleven systems have been identified. ARIES, GLOBALSTAR, ELLIPSO, IRIDIUM, and ODYSSEY will offer voice, data and radiodetermination satellite service (RDSS). STARNET and ORBCOMM will offer data, short message services and RDSS. LEOSAT is a proposal for data transmission from "smart" cars. VITASAT is proposing a data service specifically for health and education uses in developing countries. GONETS is a digital data, electronic-mail, store-and-forward service provider. INMARSAT'S Project 21 is exploring the possible combination of low-earth, medium orbit and geostationary satellites into a single system to provide world-wide telecommunications.

1035

Global Coverage Beams - Operating

SATELLITE INFORMATION	COVERAGE	CURRENT SERVICE	STATUS
GEOSTATIONARY @ 177.5°E (INMARSAT II) @ 180° E (INTELSAT)	GLOBAL	Maritime and mobile service with data, facsimile and voice transmissions	Operational

INMARSAT

INMARSAT offers global coverage and has historically utilized a combination of INTELSAT capacity and its own satellites to provide worldwide coverage. INMARSAT launched a new satellite to serve the Pacific in December 1991. This satellite, INMARSAT II (F3) will replace the MARECS-A satellite which had provided Pacific service along with an INTELSAT satellite located at 180° E. INMARSAT has announced plans to offer two new communications services in the 1990's that may be of use to the Pacific islands. INMARSAT B service will provide higher facsimile rates but utilize less bandwidth and result in lower toll charges. It is mainly intended for maritime use. INMARSAT M service will also use less bandwidth and provide digital voice-coding techniques, but will use very portable, less expensive earth terminals the size of a briefcase. The type of INMARSAT services that are offered to ships at sea could become attractive to some islands in the future as costs decrease.

Although INMARSAT has typically been a provider of maritime services, it has expanded in recent years to provide mobile services. The technology used by INMARSAT has been relatively expensive, but with the adoption of new techniques it can be expected that the cost of services should decrease.

INMARSAT has also made a commitment to the tiny island of Pitcairn to provide its sole international telecommunications satellite service and may offer similar services to others in the future.

1035

terminals in six Pacific island nations (the Cook Islands, Kiribati, Marshall Islands, Nauru, Niue and Tuvalu), as well as sites in Australia and New Zealand. PACT is a Demand Assignment Multiple Access (DAMA) system using a global beam on INTELSAT's 174° E satellite. The system uses earth terminals varying in size from 4.5 meters to 30 meters to transmit switched voice, fax and in-band data. The PACT system will expand to fifteen terminals in 1992, with four additional terminals scheduled for the Cook Islands and one additional terminal in Kiribati. OTCI also hopes to expand the PACT communication services to include data network service, teleconferencing and a broadcast service. Under the PACT system, all users share satellite channels on a demand assigned basis. Access to the satellite is controlled from OTCI in Sydney, Australia, but OTCI cannot monitor phone calls. The Australian government and OTCI granted A$3.3 million for the upgrade of Pacific island hub terminals to utilize the PACT system. The PACT system provides for domestic service from outer islands at a tariff of A$.05 per minute, regional calls to other countries within the PACT network for A$.40 per minute and calls outside the PACT network at A$.20 per minute.

SATELLITE INFORMATION	COVERAGE	CURRENT SERVICE	STATUS
GEOSTATIONARY GOES-3 satellite 175° W S-band L-band	Global coverage	voice, data, facsimile; slow scan video; non-commercial use only	Operational in over 20 Pacific Island Nations

PEACESAT

The Pan-Pacific Education and Communication Experiments by Satellite (PEACESAT) program currently uses the NOAA GOES-3 satellite to distribute non-commercial communications, such as educational, medical and environmental programming, to over 20 Pacific island nations. The GOES system operates S-band and L-band frequencies different from those used by the other geostationary satellites.[6] Voice and data communications services are supported by the system, and include teleconferencing from multi-sites, data distribution, remote database access, facsimile and slow scan video. The system uses 3 meter antennas and earth terminals have a single transmit channel capability. PEACESAT is operated by the University of Hawaii and the satellite is supplied by the U.S. Department of Commerce at no cost to the Pacific Island users. The GOES-3 satellite is located at 175° W longitude and is expected to be in service through the end of 1994.

SYSTEM TYPE	COVERAGE	SERVICE	STATUS
GEOSTATIONARY To be determined	GLOBAL	Direct Audio Broadcast	No application on file yet.

ASIASPACE

Worldspace, Inc. has proposed a series of satellites to provide direct audio broadcasts to developing areas, including Africa, Asia and South America. The U.S. Federal Communications Commission has given Worldspace, Inc. an experimental license for the construction of a satellite to serve Africa, to be known as AFRISPACE. Contracts have been signed with International Technologies, Inc. for the construction of the satellite and a control center in the United States. It is Worldspace's plan to provide direct audio broadcasts on 36 channels in the L-band, with S-band broadcasts also possible. Receiving radios, known as Starmans, will cost approximately $50-100 each, use a very small (credit card size) antenna and can be solar powered. The satellite will be launched in late 1994 or early 1995 by China's Great Wall Industry. Contracts have been signed with several users for program distribution on AFRISPACE. ASIASPACE is planned to follow activation of AFRISPACE.

SYSTEM TYPE	COVERAGE	SERVICE	STATUS
GEOSTATIONARY @ 140° E, 155° W, 145° E	GLOBAL	Not specified	Advance notice to IFRB

EXPRESS

The Russian government has recently provided IFRB notice of a new 13 satellite system called EXPRESS. Each EXPRESS satellite will have a transponder which provides global coverage. Express 10 will be located at 140° E, EXPRESS 11 at 145°E, and EXPRESS 12 at 155° W, where it will provide coverage from eastern Russia to the middle of the United States. Each satellite will have global coverage in the C and Ku bands, though not on the same frequencies as used by Western commercial satellites.

transponders which can use the South Pacific Beam are fully booked and no capacity is available for additional services. The A-1 and A-2 satellites do not have a similar South Pacific beam; the B-1 and B-2 satellites scheduled to replace them in 1993 and 1994 also do not have a South Pacific beam. The AUSSAT A-3 satellite is expected to be in service until 1997.

South Pacific Coverage beams - Proposed

SYSTEM TYPE	COVERAGE	SERVICE	STATUS
GEOSTATIONARY @ 172° E	South Pacific	Voice, data, video	Application pending before FCC; no IFRB Publication

PACIFICOM

TRW's Space and Technology Group has applied to operate a satellite at 172° E with a second satellite planned to be collocated there as demand warrants. PACIFICOM proposes Ku-band U.S. gateway services between the western continental United States and selected Asian nations and C-band services between western North America and the nations of the South Pacific (including Australia and New Zealand) and Asia as well as foreign domestic and foreign regional satellite services. Specific services include Ku-band video and HDTV, data and voice networks, private computer networks, and video teleconferencing. C-band services include commercial television collection and distribution, and high speed data. PACIFICOM proposes to sell or lease capacity on a non-common carrier basis. At this time, TRW anticipates that a significant portion of the capacity will be sold or leased for international communications originating or terminating in the U.S. not interconnected to the public switched telephone network. The balance will be used by foreign domestic or foreign regional services desirous of relatively inexpensive capacity. Launch is proposed for 1994.

SYSTEM TYPE	COVERAGE	SERVICE	STATUS
GEOSTATIONARY @ 167.45 ° E	South Pacific beam in addition to ASEAN beam	Voice, data, video	IFRB registration

PACSTAR

Pacific Satellite Inc. proposes to launch two satellites, PACSTAR-1 to be located at 167.45°E and PACSTAR-2 at 175°W. PACSTAR-1 will have a combination of C-band and Ku-band

from Guam in the Northwest to American Samoa in the Southeast covering all islands in between) and the U.S. beam (west coast, Hawaii, southern Alaska). Ku-Band coverage is similar except that there is no Pacific beam.

PANAMSAT intends to offer a full range of services including:

Video	full and reduced bandwidth analog video, wideband high definition video and audio, satellite news gathering, compressed video, cross strapped video between areas. Broadcast quality television could be available with antennas as small as 4.6 meters (or even smaller in the C-Band spot beams).
Audio	SCPC-FM 15 kHz audio, SCPC-FM 7.5 kHz audio, subcarrier audio, digital audio.
Telephony	60 channel FDM/FM, 360 channel FDM/FM
VSAT	using hub stations and TDM/TDMA modulation. Could also be mesh configuration.
Spread Spectrum	Five MHz of the spacecraft bandwidth would be devoted to one-way and two-way data broadcast.

The FCC has granted PANAMSAT a waiver to begin construction in order to meet a projected launch date in the second quarter of 1994.

SYSTEM TYPE	COVERAGE	SERVICE	STATUS
GEOSTATIONARY @ 83.3° E, 130° E, 134° E, 142.5° E	Multiple spot beams, areas not specified	Voice, data, video	IFRB Registered; two locations sold to Unicom

TONGASAT

The Friendly Island Satellite Communications, Ltd., operator of TONGASAT, has six orbital slots registered with the IFRB, located at 83.3° E, 130° E, 134° E, 138° E, 142.5° E and 170.75° E. (This is reduced from the original TONGASAT proposal of 31 orbital slots.) TONGASAT has already agreed that Unicom Satellite Corporation will be able to place satellites at two of the orbital locations with the potential of UNICOM occupying all six slots (see UNICOM below). In addition to its agreement with UNICOM, Friendly Island is proceeding with the development of the TONGASAT satellite project. TONGASAT intends to provide C-and Ku-band service using global, regional and spot beams to provide for telephone, video conferencing, high speed data transfer and home TV reception. The TONGASAT system is intended to provide high power levels to the Pacific (38.9 dbw) which will support direct interconnection using 2-3

Unspecified Coverage or No Service Proposed to Pacific Islands

SYSTEM TYPE	COVERAGE	SERVICE	STATUS
GEOSTATIONARY @ 165° W	to be determined	To be determined	Being held pending completion of TDRSS project

COLUMBIASAT

Columbia Communications, operator of the Columbia-TDRSS systems, has a conditional authorization for a satellite proposed for 165°W. After completing implementation of service on the TDRSS satellites, Columbia intends to provide additional service in the Pacific using the COLUMBIASAT satellite. The original COLUMBIASAT coverage area included service among the United States, Japan, Hawaii and Alaska. Final design of the satellite, including coverage areas and number/type of transponders, has been delayed as Columbia has concentrated on acquiring and marketing the C-band transponders on the TDRSS satellites.

SYSTEM TYPE	COVERAGE	SERVICE	STATUS
GEOSTATIONARY @ 178° W	US, Far East, Australia; No Pacific island coverage proposed	Primarily digital data for corporation use	Conditional FCC authorization; IFRB coordination completed 3/91

FINANSAT

The Financial Satellite Corporation was granted a conditional authorization by the FCC in 1986 for a Pacific Ocean Region satellite at 178° W and an on-ground spare. FINANSAT intends to offer transponders for sale or lease primarily to financial and other business institutions on a non-common carrier basis. Each satellite would carry 24 C-Band transponders with 36 MHZ bandwidth. The FINANSAT Pacific satellite would have three beams directed at the western U.S., the Far East, and Australia. FINANSAT plans to support point-to-multipoint communications to receive only terminals at customer premises as small as 18 - 24 inches in diameter and transmit/receive service to terminals approximately three by five feet. FINANSAT believes its major market is to provide customized intracorporate digital data network operations primarily to banks and other financial institutions with many international locations. The company is currently seeking financing for its proposed system.

SECTION D

Low-Earth Orbit and Other Non-Geostationary Satellites

In the past two years, several organizations have proposed constructing systems of low-earth orbiting satellites or other non-geostationary satellites to provide telecommunications services. Low-earth orbiting satellites usually orbit at a height ranging between 400 to 800 miles, much closer to the earth than the 22,500 mile high location of geostationary satellites. The earth terminals used with the low-earth orbiting satellites require relatively little power, can be very small and can be easily transported. It is anticipated that earth terminals could be hand-held units the size of mobile radios and range in price from $200 to $2,000.

Since the satellites in these systems will be very close to the earth, each satellite will only cover a small portion of the earth's surface. Many satellites will, therefore, be required for a system that provides worldwide coverage. However, even a single low-earth orbit satellite in polar orbit will pass over the earth twice a day, even if service to that area is not intended. Low-earth orbit systems therefore have the potential of providing service to the Pacific basin, whether or not the Pacific is the intended service area.

Two types of systems have been proposed, systems using VHF frequencies or those which use the L-band frequencies.

- VHF based systems are designed to support only data transmission. Systems included in this category (GONETS, LEOSAT, ORBCOMM, STARNET, and VITASAT) are low-earth orbiting systems.

- L-band based systems are designed to support voice communications as well as data transmission. Systems included in this category (ARIES, GLOBALSTAR, and IRIDIUM) are low-earth orbiting systems.

  The ELLIPSO system proposes satellites in highly elliptical orbits.

  The ODYSSEY system will use satellites in high-orbit, approximately 10,239 km above the earth.

  INMARSAT has announced that it is considering a system which could combine geostationary, low-earth orbiting and/or high elliptical orbit satellites in a single system.

partners are Defense Systems (which has built more than 20 microsats for the U.S. Department of Defense), Microsat (which is developing the Orbital Express launch system for small satellites) and Pacific Communications (which developed specifications for Aussat's MSS system). User terminals are expected to cost about $1,500.

TYPE	SATELLITE CONFIGURATION	PROPOSED SERVICE	PROPOSED USER FREQUENCIES (MHz)	SATELLITE-GATEWAY LINKS
Highly Elliptical Orbit	24 Satellites 63° inclination 2903 Km apogee 426 Km perigee	Voice and data, RDSS	1610-1626.5 (U) 2483.5-2500 (D)	NA

ELLIPSO

Ellipsat Corporation has filed for a 24 satellite system that will use elliptical orbits to provide voice mail, RDSS and interconnection to terrestrial cellular services. Each satellite will weigh 175 Kg and will be in an orbit with an apogee 2903 Km and a perigee of 426 Km. Four orbits with six satellites in each orbit will be required for global coverage, though Ellipsat intends to start service for just the United States using nine satellites. The system plans to use 1610-1626.5 Mhz for uplinks, and 2483.5-2500 MHz for downlinks, with no C-band or intrasatellite links. ELLIPSO hand units will be available for satellite access. Add-on units will also be available to add ELLIPSO RF electronics to existing terrestrial cellular systems. The targeted user cost will approximate cellular system pricing, or about $.60 minute.

TYPE	SATELLITE CONFIGURATION	PROPOSED SERVICE	PROPOSED USER FREQUENCIES (MHz)	SATELLITE-GATEWAY LINKS
Low	48 Satellites 52° inclination 1389 Km high	Voice and data, RDSS	Plan A: 1610-1626.5 (U & D) See Note	C-band

Note: Globalstar has three alternative frequency plans. Plan B uses L-band for uplink, S-band downlink and C-band feeder links to gateways. Plan C uses L-band bidirectional to users and S-band bidirectional to gateways. (Plan A uses C-band feeder links between the satellite and the gateways.)

GLOBALSTAR

Loral Cellular Systems is a partnership between Loral Aerospace, a satellite manufacturer, and Qualcomm, a provider of two-way mobile satellite communications systems and digital cellular

1046

the development of the IRIDIUM system. User terminals are projected to cost between $3,000 for a full system down to $200-$300 for a paging or RDSS only unit. The IRIDIUM system is targeted at high-end users who can pay a usage charge of approximately $3 per minute. Motorola recently purchased the licenses for operating on the 1610-1626.5 MHz frequencies from the bankrupt Geostar Corporation and is asking the Federal Communications Commission to transfer the licenses from Geostar to Motorola.

TYPE	SATELLITE CONFIGURATION	PROPOSED SERVICE	PROPOSED USER FREQUENCIES (MHz)	SATELLITE-GATEWAY LINKS
Combination of types	To be determined	To be determined	To be determined	To be determined

INMARSAT PROJECT 21

INMARSAT has announced its "Project 21," which intends to provide INMARSAT service into the 21st century. Currently, Project 21 is not a firm proposal, but is an announcement of interest by INMARSAT. The goal of Project 21 is to provide global voice services to hand-held terminals by the end of the decade. These hand-held voice terminals would interface with terrestrial cellular systems. Targeted costs for the terminal would be $1,000 (US) with less than one dollar a minute for service charges. INMARSAT has indicated that it will consider using a combination of geostationary satellites as well as low-earth orbiting, or high earth orbit satellites. The INMARSAT Board of Governors has not endorsed the Project 21 concept, but has authorized INMARSAT to do technical research in this area.

TYPE	SATELLITE CONFIGURATION	PROPOSED SERVICE	PROPOSED USER FREQUENCIES (MHz)	SATELLITE-GATEWAY LINKS
High	12 Satellites 55° inclination 10,239 Km high	Voice and data, RDSS	1610-1626.5 (U) 2483.5-2500 (D)	Ku-band

ODYSSEY

TRW's ODYSSEY system will consist of 12 satellites in medium earth orbit, 5,600 nautical miles above the earth. The ODYSSEY system will provide voice, data and RDSS service and is designed to complement terrestrial cellular service. Four satellites will be in each of three planes inclined at 55°, and will orbit the earth once every 6 hours. Each satellite will have 19 spot beams and will be visible over the user's terminal for 1.5 hours. The system proposes to use the

TYPE	SATELLITE CONFIGURATION	PROPOSED SERVICE	PROPOSED USER FREQUENCIES (MHz)	SATELLITE-GATEWAY LINKS
Low	18 Satellites 40° inclination 970 Km high	Data from smart cars	148-149 (U) 137-138 (D)	NA

LEOSAT

LEOSAT Corporation has proposed a satellite system that will provide "smart car" low speed two-way data transmission, primarily from automobiles and trucks. Transmitters could be integrated into automobile components, fixed transmitters would be used for monitoring, and personal portable units could be used for individual use. Individual radios could cost less than $200. Contact time between a user terminal and the satellite system would be less than 16 minutes. The LEOSAT system would initially consist of two satellites, primarily to serve the United States. A world-wide system would eventually require 18 satellites. Satellites would be manufactured by DSI Microsat and placed in an orbit 970 Km above the earth, inclined at 40°. The system proposes to operate on the 148-149 MHz and 137-138 Mhz bands. LEOSAT has signed an agreement with Canadian Satellite Corporation to cooperate on implementing LEOSAT technology in Canada.

TYPE	SATELLITE CONFIGURATION	PROPOSED SERVICE	PROPOSED USER FREQUENCIES (MHz)	SATELLITE-GATEWAY LINKS
Low	20 Satellites 18 in 40°-60° inclination 2 in polar orbit	Data, short messages, RDSS	148-149.9 (U) 137-138 (D)	NA

ORBCOMM

Orbital Science's ORBCOMM system envisions 18 satellites with six satellites per plane, inclined at 40°-60°. An additional two satellites would be in a polar orbit to serve the North and South polar regions. ORBCOMM satellites would provide very short (no more than 30 characters) two-way data packets compatible with the X.25 packet protocol. Orbital Science also manufactures satellites and satellite launchers, and would construct the ORBCOMM satellites and launch them on its Pegasus launcher. The ORBCOMM system proposes to operate on the 148-149 MHz and 137-138 Mhz bands and also would have a 400 Mhz downlink to provide time and positioning information. Estimated cost of user terminals range from $50 for a basic terminal to $150 for

frequency plan uses 400.15-401 Mhz uplink, 137-138 Mhz downlink, and is compatible with the ORBCOMM FDMA system. The other frequency plan is to use 148-149.9 Mhz uplink, 400.15-401 Mhz downlink in order to be compatible with a spread spectrum system as proposed by Starsys. VITA currently is operating a prototype system using the UoSAT-3 low-earth satellite designed by the University of Surrey, England. This system is providing health, energy, and educational communications services to sites in Africa. The UoSAT system permits the transmission of from 50 to 250 pages of text twice a day. The next generation VITASAT will have the capacity of transmitting up to 350 pages of text. VITASAT is currently experimenting with terrestrial packet radio network telecommunications in developing countries which could be linked with VITASAT. Fixed and portable terminal assemblies will be manufactured by VITA and are expected to be sold for $5-7,000.

Endnotes

1. While many consider undersea submarine cables as alternatives to satellite communications, submarine cables across the Pacific have as their primary use the exchange of international traffic between the Americas and Asia. Submarine cables have and will continue to bypass the small island nations of the Pacific basin. A recent worldwide study of almost 500 submarine cables indicates that only four Pacific islands are connected by submarine cable: Hawaii, Guam, Fiji, and Papua New Guinea (Port Moresby). None of the current submarine cable projects under development, including the North Pacific Cable, TASMAN 2, TPC 4, Asia Pacific Cable, PacRim East, and TPC 5 will provide new service to unserved Pacific islands. *1990 World's Submarine Telephone Cable Systems,* NTIA-CR-91-42, October 1991.

2. The authors would like to acknowledge the assistance of the many individuals and satellite organizations who provided information for this study and to the staffs at the FCC and NTIA for their assistance in this project. Special thanks are due Charles Rush, Hal Kimball and Craig Moll of NTIA for their thoughtful guidance in the preparation of this paper.

3. For example, the PEACESAT system uses a GOES meteorological satellite system that has been modified for voice and data communications use.

4. For example, a satellite located at 150° West longitude would require an elevation angle of less than 6° above the horizon for an earth terminal in Belau. Likewise, a satellite located at 140° East longitude would require an elevation angle of 10° above the horizon for an earth terminal in French Polynesia.

5. After the breakup of the former Soviet Union, the Russian Republic assumed control of the Ministry of Communications and appears to be in control of the Soviet space program. Therefore, we have adopted the convention of referring to the satellite systems and activities of the former Soviet Union in this paper as Russian.

6. The terms S-band, L-band, C-band, Ku-band and Ka-band are commonly used to refer to general satellite frequencies. In common usage, frequencies in the L-band are in the 1500-1600 Mhz range, S-band frequencies around 2500 Mhz, C-band in the 3/6 Ghz range, Ku-band in the 10/14 Ghz area and Ka-band in the 18/30 Ghz range. However, the specific frequencies utilized will vary in different countries or areas of the world.

constructed by Hughes based on its H-376 satellite and launched in 1994 by Arianespace. The Malaysian partner is Bina Riang Pte. Ltd. The Philippine Long Distance Co. is one of six users signed up for the project. Malaysia has not started IFRB coordination for orbital locations for Measat.

Spinning New Legal and Regulatory Webs for Telecommunications Services in the Pacific: IVANS, Trade Agreements and the Uruguay Round

by

Jeffrey P. Cunard
Debevoise & Plimpton
Washington, D.C.

Pacific Telecommunications Council '92
Honolulu, Hawaii
January 15, 1992

I. Introduction: Development of a Multi-tier Legal and Regulatory Regime for the Telecommunications Services Sector

The theme of this Fourteenth Annual Conference of the Pacific Telecommunications Council focuses on telecommunications integration in the Pacific. The challenge, of course, is how to integrate while disintegration -- the emergence of competition within and between countries -- is more the order of the day. When the colonial powers controlled the provision of telecommunications services in the region, the web of interlocking relationships almost defined the concept of integration. Not much changed when governments, nationally-owned PTTs, or private monopolies assumed responsibility for the provision of services in the region.

Now, in some sense preceding or perhaps mirroring the transformation of the world's geopolitical order -- the disintegration of the East Bloc and the Soviet Union, the emergence of democratic regimes around the globe, a recasting of military and economic alliances -- is a transformation of the telecommunications sector. As we have heard throughout the PTC, monopoly is being replaced by competition, privatization efforts are well advanced, countries are lining up to position themselves as regional, if not international, hubs. Each country has come to understand that technologically advanced and economically competitive telecommunications services are critical to broader economic growth. Industry is attracted by high-quality, efficient and low-cost telecommunications services. With the customer having a greater role in directing the evolution of sector, the traditional monopolistic approach no longer has either vitality or viability.

Paralleling this remarkable transformation is an extraordinary metamorphosis in the rules of

the game. As we all know, historically international telecommunications services were provided -- some would say jointly provided -- by two monopolists that had a correspondent relationship. Beyond the contractual arrangements that constituted the legal framework for that relationship, there was little else in the way of law or regulation that structured the relations between two providers of international services. To be sure, there was some government involvement in oversight of a PTT's operations. The ITU always played the most important -- and critical -- technical role in achieving global interconnectivity and establishing principles, in the form of recommendations, to guide international providers.

Today, however, with the transformation of the sector we have an entirely new set of rules. The days of a sleepy, predictable legal regime -- like that of an essentially public utility approach to the provision of telecommunications -- are forever behind us. As a lawyer, I know this all too well. What we are witnessing is not just bounty for the legal profession, but the creation of a set of principles -- and innovative approaches toward the establishment of such principles -- that will guide international providers into the next century.

What I have in mind, of course, is the development of a multi-tier legal and regulatory regime in which governments and customers are as much players as traditional carriers. What I have in mind is an overlay on top of traditional correspondent relations. What I have in mind are 1) the new bilateral arrangements for the provision of international value-added network services ("IVANS"); 2) informal government-to-government consultations on telecommunications issues; 3) regional arrangements, including those of the European Community, the incipient North American Free Trade Area ("NAFTA") and the Asia-Pacific Economic Cooperation ("APEC") grouping, about which much has already been heard at this conference; and 4) of course, multilateral arrangements, particularly those that may (in our lifetime) emerge from the Uruguay Round. I'd like to talk about each of these developments in the Asia-Pacific context.

II. New Bilateral Arrangements for IVANS

The extraordinary amount of effort that has been put in establishing new arrangements for the provision of IVANS -- and the popularity and success of such efforts for providers of value-added services and users -- is well known to telecommunications "groupies." Given the novelty of these arrangements and

the importance that have had for regional trade and economic growth and integration, it is, at least for me, curiously that they seem to have -- by and large, and with a few notable exceptions -- escaped the focused attention of academics, legal scholars and political scientists.

I will not canvass in detail the IVANS agreements that have been reached globally or in the Pacific region except to note that their genesis was in this part of the world. That is not at all startling -- given the innovative thinking that has characterized both economic growth and the provision of telecommunications services in the Asia-Pacific, it should surprise no one that new arrangements started here, as well.

The purpose of IVANS arrangements, of course, is to permit the offering of value-added services internationally. They are intended to remove regulatory and technical obstacles to service provision and to mitigate or overcome discontinuities in national regulatory schemes. They are concerned with a host of isssues that have kept lawyers, service providers, users and government officials busy for years: the absence or presence of any requirements that a provider of IVANS interconnect with other such providers; whether government approval of operating agreements is required; whether and how providers of IVANS are licensed; the use of proprietary protocols in the offering of a service; and the pricing of underlying telecommunications services, including whether they can or should be priced on a volume-sensitive basis.

From the standpoint of policy-makers in this region, the provision of IVANS has provoked fundamental questions about the structure or arrangements by which telecommunications services are provided:

> Which services should be provided competitively and how are such services related to, or may be substitutes for, services that have been reserved to a monopoly?
>
> What is the impact of the provision of end-to-end services on the "jointly provided" model?
>
> Do IVANS increase use of network services by stimulating demand or do they wreak economic harm by encouraging bypass of the public switched network?
>
> And, perhaps most importantly, how should those administrations that supply the network be compensated by those who use it to provide IVANS?

At a more concrete level, as government officials, users, and carriers attempt to work out bilateral arrangements to facilitate the provision of IVANS they confront another set of questions. First, who will or may provide IVANS? Monopolists? Carriers? National providers of value-added or enhanced

services? A joint venture established to offer IVANS on an end-to-end basis? Users or others not generally regarded as being in the telecommunications business?

Second, how will IVANS be provided? From abroad or from a third country? On an end-to-end basis or on a jointly-provided basis? Via leased lines or on a switched or dial-up basis? Will the leased lines be provided over a network separate from a network of leased lines that previously had been used solely for intracorporate purposes?

Third, to whom will IVANS be provided? To the general public? To a particular industry sector? To members of a closed user group? To entities with which the IVANS provider has a business, contractual or corporate relationship?

Fourth, what services will providers of IVANS be permitted to offer? The full range of services that may be provided competitively in one, or both, of the countries entering into the agreement? Services set out on a detailed list or, rather, described more generally? All services but those that might cut too deeply into the revenues or traffic stream of the monopoly or established carriers?

Some of the most innovative approaches toward thinking about and answering these questions has been in this region, stimulated by officials from the United States, from Japan, from Hong Kong, the Republic of Korea and other countries. Let me make just a few observations.

First, in these bilateral arrangements, the "lowest common denominator" -- that is, the least liberal regulatory regime -- will prevail. One country usually will be reserving on, for example, the inclusion of a particular service in an IVANS arrangement to accommodate its more restrictive regulatory framework.

Second, the IVANS arrangements may, in some cases, reflect the fluidity in the sector: they establish a process by which the parties can review progress under the arrangement and attempt to seek greater liberalization in the future. This process can be regularized in the form of an annual review, it can be more informal, or it can be directed toward specific issues left outstanding by the negotiations.

Third, there are various types or models of arrangements, which can be illustrated by way of the various IVANS arrangements that the United States has with a few countries in Asia. The U.S.-Japan IVANS arrangement -- the very first in the world -- emerged from trade negotiations. It is highly detailed;

the negotiations were protracted; the arrangement grew in stages and has often been revisited, rewritten and recodified. I suspect that that will continue for the foreseeable future.

The issues on which the negotiators focused were far-reaching, raising each of the questions that I posed above. They included such difficult matters as defining intracorporate communications, and shared or joint use. Importantly, at least from the standpoint of regional integration, the U.S.-Japan arrangement contains a provision that addresses whether there is a need to conclude arrangements with third countries, for services traveling beyond, or being routed through, Japan.

Nonetheless, although the U.S.-Japan IVANS arrangement has done much to facilitate the offering of services between the two countries, it is far from perfect. The Japanese, for example, are not altogether persuaded that traffic coming from Japan, being routed through and processed in the United States, and then sent on to a third country, falls within the scope of the arrangement. This position, if it were to prevails, would seem inconsistent with the intent of the arrangement and would have serious consequences, in my view, for the extraterritorial exercise of jurisdiction by the Japanese to traffic beyond their borders.

After its initial agreement with the United States, Japan then rushed ahead to negotiate an IVANS arrangement with the United Kingdom. The U.S. had been trying to do so for some time, and within a few months after the Japan-U.K. arrangement, also concluded one with the United Kingdom. In some sense, the U.S.-U.K. arrangement is at the other end of the spectrum from that of the U.S.-Japan agreement in terms of simplicity, approach and scope. It is, in essence, not much more than a simple exchange of letters that says "what is permitted domestically is also permitted between our two countries."

The U.K.-Japan arrangement is somewhere in the middle -- but much closer to the U.S.-U.K. end of the spectrum. That arrangement is important, moreover, because it serves as a paradigm for many of the other arrangements in this part of the world. In particular, the Japan-U.K. arrangement contains a list of permitted services, which was not true of the U.S. agreements with either Japan or the U.K., which either excluded certain services or made reference to the domestic regimes, respectively.

The U.S.-Hong Kong agreement, for example, which was concluded about one year ago, was, in this respect, modeled to a certain extent on both the U.S. and the Japanese arrangements with the United

Kingdom. The U.S.-Hong Kong arrangement is relatively simple -- a couple of pages, plus an annex that lists the services that are "value-added." It was negotiated rather quickly, and also contains a provision for reviewing whether certain services should be included within the arrangement.

Japan has been pursuing IVANS arrangements in the Asia-Pacific region very aggressively. In the last year or so, it entered into an arrangement with Canada. It has been discussing such arrangements with Hong Kong and Australia for some time. It is anticipated that these are or will be similar to the arrangement with the United Kingdom.

Last summer, the United States also concluded an IVANS arrangement with the Republic of Korea. Much like the agreement with Japan, this arrangement also emerged from trade negotiations between the two countries. The arrangement is simple and straightforward, based on a model proffered by the Koreans. In the eyes of many, this arrangement is clearly intended to be transitional, pending the conclusion -- about one month from today -- of more comprehensive trade talks between the United States and Korea on market access in the telecommunications sector. And, after concluding an agreement with the United States, Korea did so with Japan.

With the strongest interest and support of the U.S. private sector, the U.S. Government continues to pursue arrangements to facilitate the provision of IVANS services both outside and within the region. U.S. industry sees substantial benefits from these arrangements. Between the United States and Japan, for example, almost twenty companies have IVANS licenses (under Japanese law). The new services are seen as good for industry in both countries. The arrangements increase traffic. They promote arrangements between and with other countries. They are the forum for a dialogue to remove barriers and to develop a common threshold of what constitutes an acceptable level of regulation for IVANS.

Specifically, U.S. industry is particularly keen on arrangements with Australia and Taiwan. In some situations even an exchange of letters stating that there is no obstacle to the provision of IVANS between the two countries, or letters along the lines of the U.S.-U.K. agreement, would suffice. It is fair to say that, having had a taste of a new legal regime for the provision of international services, at least U.S. businesses are eager for more, for a web of arrangements spanning the Pacific, and the globe.

We could find ourselves "hung up" on whether these arrangements are "trade" agreements or are more technical agreements to clarify the terms by which IVANS can be provided between any two (or more) countries. In the long run, the taxonomy matters less than that they are concluded and that they achieve their intended results.

III. Bilateral Consultations

Beyond the more formal discussions between countries that are intended to conclude in a document -- in an IVANS arrangement or agreement -- governments are now talking or consulting on telecommunications matters of mutual concern. These consultations may be no more than fact-finding discussions, or an informal exchange of views between government officials, or between private sector delegations. They have occurred, by way of example, between the United States and Taiwan, the United States and Singapore, and between Japan and Australia.

These discussions, whether exclusively at a governmental level, or with the involvement and participation of representatives from the private sector, are entirely complementary to the discussions that have taken place with regard to the offering of IVANS. They may even lead to IVANS agreements.

The portfolio of issues raised in these consultations can be far broader, however. They can be targeted at what are perceived as specific barriers -- such as volume-sensitive pricing -- or equipment attachment policies. They can be the forum for rendering advice on the corporatization of a telecommunications administration or on a new national telecommunications law. What is important, here, is that countries are talking at multiple levels. They are engaged in trying to achieve an "interconnectivity" of regulation to facilitate the provision of services internationally.

IV. NAFTA

Hudson Janisch has already given an excellent paper on the U.S.-Canada Free Trade Agreement ("FTA"), which presages the NAFTA. Although it is commonly thought that the NAFTA discussions are of concern principally to "The Americas," all three countries -- Canada, the United States and Mexico -- are, of course, very much countries of the Pacific Region. Moreover, the development of a free trade area in North America will have significant implications for the rest of the region, both in its own right

1033

and as a potential example -- or model -- of further regional agreements in the Americas and elsewhere in the region. And, to be candid, a NAFTA would be seen as a constructive "fall back" if the Uruguay Round ultimately fails.

The NAFTA discussions that are currently ongoing are intended to build upon -- and expand -- the Canada-U.S. FTA. That bilateral agreement, of course, only addresses the so-called "enhanced services" side of the telecommunications services sector. It took a surprisingly long time to negotiate, especially given that the two countries have very similar regulatory structures and concepts.

What the two countries define as "basic" services were specifically excluded from the FTA. Why? To protect domestic markets and, at least from the standpoint of the United States, to achieve some equity or fairness in the relationship. U.S. negotiators asked why the U.S. basic services market should be frozen open for the Canadians, when the Canadian market was not as open for the Americans?

This exclusion, I should point out parenthetically, is not without problems. There continue to be controversies, for example, over the routing of intra-Canadian or Canada-third country traffic through the lower-cost service providers of the far-more-competitive United States. This practice has been the subject of a decision last year by the Canadian Radio-television and Telecommunications Commission ("CRTC"). The CRTC issued a ruling that is intended to prohibit Canadian users from sending traffic through the United States, even where that might make sense from the standpoint of network architectures or cost. Inevitably, despite the purported exclusion of basic services from the FTA, this issue will be put squarely on the table for discussion between the two countries in the context of the NAFTA.

All this, however, is for today's discussion a precursor of what is promised for the NAFTA. The highest possible priority -- as you all know -- has been put on concluding the NAFTA discussions quickly and with the greatest possible benefits for all three countries. In the NAFTA discussions, all three parties have agreed that telecommunications services are of very high priority indeed. A separate working group for telecommunications issues has been established. Discussion papers and, now, draft texts have been exchanged. Recently, a consolidated paper was prepared by the negotiators. This document is a major step forward in the negotiations because it reflects a consensus view that the NAFTA arrangement should set out the

conditions for access to and use of telecommunications services.

To be sure, there are differences among the parties with regard to range of issues. The Mexicans have put on the table for discussion a list of the telecommunications barriers in their own market. They have, as well, identified barriers in the other markets, including that of the United States.

The texts that are being reviewed and negotiated build on the principles of market access that have been developed and fleshed out in the Uruguay Round. I will turn to these in a few minutes.

Again demonstrating the extent to which the development of an international telecommunications regime is no longer entirely the closed club that it once was, the private sectors from all three countries have been deeply and intimately involved in the NAFTA process. They have assisted in the identification of barriers in the other markets. They have advised their governments on what to seek -- and what to protect -- in the exercise of removing barriers. They have met -- and continue to meet -- with their private sector counterparts, to exchange views and to try to establish a common position on what would be desirable for the telecommunications segment of the NAFTA.

A monumentally critical issue is the extent to which "basic" services are "on the table" for discussion. Although, as mentioned, they were not part of the FTA, the Mexicans have not foreclosed the possibility that basic services would be included in the NAFTA. (They would insist, of course, that the monopoly on long distance telephone services that Telefonos de Mexico has until 1997 not be disturbed by market access in basic services.) The U.S. private sector, even including some of the carriers, seems to be much more willing to have basic services be part of the NAFTA negotiations than, for example, part of the Uruguay Round.

In this regard, for the first time, the private sector has laid out the various criteria for affording Mexicans and Canadians access to the U.S. basic services market on the basis of equity and reciprocity. In the eyes of the private sector, at least, meaningful market access on the part of the Canadians or Mexicans would include:

1) the ability to build, own and operate networks and services;

2) ensuring that new entrants are able to enter into interconnection and access arrangements with the incumbent provider of services on nondiscriminatory terms and conditions and at a

1051

price that is cost-based and under transparent processes;

3) that access charges, if any, be cost-based;

4) refraining from imposing conditions on licenses to provide "basic" services, such as the obligation to provide local services;

5) implementing and enforcing strict safeguards that prevent the incumbent from cross-subsidizing between competitive and non-competitive businesses;

6) adhering to fair terms and conditions for billing and for the termination of traffic;

7) requiring that there be non-discriminatory and cost-based access to all network services features, functions and capabilities of the incumbent provider; and

8) an equivalence in the level of interconnect and access charges among the three countries so that the opportunities to compete are economically comparable.

As I will note briefly below, the U.S., as part of the Uruguay Round, has tabled five principles that would, when satisfied, constitute openness in basic long-distance services. When the other "major telecommunications markets" bind themselves to these principles, then the U.S. would be prepared to grant full most-favored-nation treatment to such services.

For the NAFTA, these principles may signal the terms and conditions, which, if met by the Mexicans and Canadians, would frame the environment in which the U.S. would bind itself to market access and full national treatment. The U.S. will continue to insist on reciprocity in basic services. Whether the Canadians or the Mexicans will be willing to go along is still very much an open question, however.

Should there be market access for the provision of basic services among the three countries, it will be the most integrated region -- from a telecommunications perspective -- in the world. Ahead of Western Europe, which has drawn the line for market access at the provision of infrastructure and public switched telephony and telex. Nowhere else in the Asia-Pacific region (with the exception of the New Zealand regime and the position that that country has taken on the issue in the Uruguay Round negotiations) is there talk of permitting unlimited market access to a nation's market for basic telecommunications services.

Thus, for the rest of the region, a successful conclusion to the NAFTA may well be an historic and potentially very significant watershed. It will signal that it is possible to create a free trade area among disparate economies, including the sector in which we are most interested. It will pose a challenge to other

1062

trading blocs in the region. And, to the extent that telecommunications is the foundation for broader economic expansion, what will be the impact of the integrating influence of the telecommunications services component of the NAFTA on the competitiveness of other countries and subregional or regional units?

The thrust for market access, openness and competition in the telecommunications sector, ultimately to include basic telecommunications services, comes from the widespread realization that telecommunications is an extraordinarily important vehicle for regional growth, facilitating cross-border trade and economic integration. This is the understanding of participants in the NAFTA negotiations at all levels -- governmental and private sector.

At least from this private sector perspective, the NAFTA negotiations have been encouraging. Negotiators are making what looks to be real progress. They are engaged on the issues. There appears to be a genuine feeling of cooperation, coupled with firmness on points of principle. Substantial and formidable barriers are being discussed and, we hope, toppled.

V. A Long Time A'Coming or Will it be Worth the Wait?: The Uruguay Round

Finally, then, to turn to the longest running act around: the Uruguay Round. Will there be an agreement or not? The telecommunications component of the negotiations in the Group of Negotiations on Services ("GNS") is irrelevant for purposes of answering this question. Thus, all of what follows (like all that has gone on for the past four or five years) is as likely to be overtaken by events as not.

The real issue for cognoscenti of telecommunications and trade in services is whether all the time and resources, of governments and private sector advisors and interested parties, that has been put into crafting the telecommunications-specific provisions of the Uruguay Round has been worth the effort. It is too early to render definitive views on that question -- but, at the risk of being unduly provocative, I will venture some observations.

A. Structure of the Services Elements of the Uruguay Round

Let us briefly review the structure of the services elements of the Uruguay Round negotiations. The GNS has been negotiating a framework agreement on services, to culminate in a General Agreement on Trade in Services ("GATS"). The GATS will have has two fundamental operating principles.

1063

First, certain general obligations and disciplines apply to all services -- including telecommunications -- of a party (unless a party has taken a specific derogation thereto). Second, specific commitments, including market access and national treatment, are accorded all providers of services listed on "schedules" of a party.

Thus, the general principles of the GATS would apply to telecommunications services, as a sector, and to any of its sub-sectors, including the provision of value-added services. These principles include such important obligations as according service suppliers most-favored-nation ("MFN") treatment, ensuring transparency in laws and regulations applicable to such services, committing that domestic regulation (where specific sectoral commitments are undetaken) does not constitute a barrier to trade and is applied in a "reasonable, objective and impartial manner," and preventing monopolies from abusing their position when supplying services for which specific commitments have been made and that are outside the scope of their monopolies.

The most powerful principles would apply to a particular service sector only where a party has specifically -- and as a result of negotiations with other parties -- committed to doing so. The principle of market access, where applicable, would bar countries from limiting the number of service providers in a sector or from imposing any other restrictive measures (including foreign ownership limits) on foreign service suppliers. The national treatment principle prohibits discrimination in favor of a national service provider and against a foreign supplier. Additional commitments may be negotiated.

Much, then, turns on whether telecommunications services are listed on a country's schedule of commitments. Beyond the spare text of the framework agreement, therefore, the essence of the GNS negotiations is at the second layer: identifying and negotiating away barriers to market access on a sectoral basis. These negotiations, which are both protracted and intensely political, require negotiators to identify specific barriers and then engage in "horse trading" with their trading partners. Country A will agree to liberalize on value-added services, for example, in exchange for Country B's commitment to liberalize in that, or some other, sector or sub-sector. Other than the brute force of political pressure and the articulation of specific interests by industry, it is difficult to imagine how these sectors are evaluated -- and valued as to the opportunities that market access might present to foreign suppliers -- for purposes of this exercise.

1054

Countries have tabled some of their "offers" in the request/offer process that I have described. Three more rounds of the process are anticipated -- now extending through early March. To date, developed countries have, by and large, made offers for meaningful commitments in the telecommunications sector, particularly with respect to value-added services. Some developing countries have as well, in some cases conditioned by licensing or other restrictions. As the negotiations move forward, there are reasonable prospects for improving these offers, or convincing countries to put value-added services on their schedule of commitments.

The third tier of the GNS structure is the much talked-about "annex on telecommunications." There have been innumerable iterations of this annex and one cannot begin to chronicle the twists and permutations throughout its nearly two-year old life. The justification for an annex relies on the definition of "measures by Parties affecting trade in services" that appears in the very first sentence of the very first article of the draft GATS. Such "measures" would include measures with respect to "the access to and use of, in connection with the supply of a service, . . . public telecommunications transport networks and services." The latest draft of the annex states that it has the "objective of elaborating upon the provisions" of the framework agreement with respect to such measures. In short, the annex, then, is intended to put some meat on the bare bones of what is meant by service suppliers having access to and use of public telecommunications networks and services.

There always has been some uncertainty as to how the annex is meant to dovetail with the scheduled commitments of a party. The question, in some sense, is whether the annex was (or is) intended to be liberalizing in its own right, or whether liberalization, in the form of market access, only can come through negotiated commitments for particular service sectors.

The U.S. initially had hoped that the annex would be a powerful force for liberalization, on its own, supplementing and complementing the scheduled commitments as to which the annex applies. In fact, although there are some liberalizing elements in the annex, its basic utility in that regard has been, over time, rather diminished.

The GNS working group on the telecom annex has been chaired by Bob Tritt, of Canada.

1005

Those negotiating the annex have kept their eye on the ball: to deliver services within a country, or on a cross-border basis, requires that service suppliers have access to -- and are able to use -- the telecommunications networks and services of companies that are, by and large, monopolies or exclusive providers of service.

The telecom annex could apply to all would-be suppliers of services to a country. Therefore, it is not restricted only to service suppliers in the telecommunications sector, but to all entities using telecommunications services. To trigger the application of the annex, however, a country must list the service on its schedule of commitments. In other words, without a party committing to market access, a would-be supplier of a service cannot claim the rights and privileges of the annex.

Allow me to turn to two controversial, telecommunications-related issues that have been raised in the Uruguay Round negotiations. They are: 1) coverage of "basic" telecommunications services and 2) the need for or value of the telecommunications annex.

B. Whither "Basic" Services?

First, as most GATT aficionados well know, the issue of whether "basic" telecommunications services should be included within the GNS negotiations and, if so, on what terms, has been the subject of the fiercest controversy, one that has even made its way into the general press. The issue is whether, on the one hand, parties, in the GNS agreement, should commit to keeping open markets that are now competitive or, on the other hand, they should be permitted to exclude from the obligations of the framework agreement one of their own competitive sectors when other countries do not provide equivalent market access. The sector we are talking about, of course, is principally the U.S. basic services sector.

In general terms, there is probably more interest on the part of users in having basic services covered by the GNS than there has been or is on the part of carriers. U.S. domestic carriers in particular, with the concurrence of some in the U.S. Government, have been concerned that the U.S. should not freeze its basic services market open (by entering into the GNS) while that market is closed in virtually all of the trading partners of the United States. Only a few countries have, even to a limited extent, put basic services on the table. In this part of the world, two countries have done so, one conditionally.

1066

The decision of the U.S. to take a derogation from the MFN principle for basic services, therefore, met with considerable resistance and outcry, both from within and outside the United States. For many it was, at least, a conceptual stmbling block to the successful conclusion of the negotiations on the GATS.

In response to other countries, the U.S. has, as noted, above, tabled a proposal that is, in part, intended to break an impasse on telecommunications in the Uruguay Round. The U.S. would commit to extend MFN to both domestic and international long distance services, on the condition that the major trading partners would agree to open their own long distance telephone markets to international competition. The challenge to the "major telecommunications markets" is to meet the liberalizing conditions set by the United States within three years after entry into the force of the GATS, or January 1, 1996, whichever comes first.

Frankly, this conditional commitment by the United States has met with some degree of skepticism by other countries and by some in our own private sector. Given the conditions -- and the fact that all major markets would have to commit to them -- it is very unlikely that the challenge set by the United States could be met. In other words, to many observers it seems virtually certain that the U.S. derogation from MFN for basic services will remain in effect. Indeed, a country other than the United States has little incentive to open its market -- for purposes of trying to gain entry into the U.S. market -- unless the other major countries do so as well. The net result may well be one that could have been foreseen: other countries will now take derogations from MFN for their own basic services sector.

C. The Telecom Annex

Turning to the telecom annex, the current draft -- which is nearly final -- reflects a balance between users and regulators. The U.S. private sector had gone into the Uruguay Round hoping that the annex would be a Magna Carta, a Bill of Rights, for users of telecommunications services. The original text of the annex tabled by the United States listed in detail what comprised the critical components of access to and use of public telecommunications transport services:

-- the ability to resell or share telecommunications services to provide a permitted service;

-- the freedom to purchase or lease and attach customer premises equipment, restricted

1057

only by a "no-technical harm-to-the-network" standard;

-- the ability to interconnect leased circuits with a customer's, or another's, leased circuits, on a mutually negotiated basis;

-- the performance of switching, signaling, and processing functions in connection with such interconnection;

-- the interconnection of leased circuits with the public switched network on reasonable and non-discriminatory terms;

-- the ability of service suppliers and users to choose from among a menu of services, which will be priced at cost-based rates, and, in the case of leased lines, made available also on a flat-rate basis; and

-- the ability to move, store and process information within and across national borders.

This list of "rights" is formidable. It was too tough for many countries to swallow. They did not want to afford as much "access" as some in the United States had wanted, and firmly adhered to the view that regulators need the flexibility to adjust the regulatory environment in light of particular needs and economic circumstances.

Consequently, after much wrangling, the annex that has been negotiated represents a very substantial retreat from the original U.S. position. Although the fundamental structure of the document is not far-removed from what was tabled by the United States, several of the rights mentioned above have been omitted entirely. Others, of course, remain.

The real transformation is that the annex expressly sanctions imposing some conditions on access to and use of public telecommunications transport networks and services. Although the extent to which such conditions can be imposed is significantly limited by the text, some observers are doubtful that those textual restrictions actually will curtail regulatory fervor.

At bottom, therefore, some users, including would-be providers of value-added services, and carriers, are disappointed in what has been produced. A particular sore point, I should note, is that the annex, although ostensibly oriented toward access to and use of public telecommunications services, also would govern, in some respects, arrangements entirely between two suppliers of value-added services. It is somewhat of a stretch, of course, to say that regulating such arrangements has much to do with the terms of access to or use of public telecommunications services.

1065

The document is, as mentioned above, now roughly balanced between what users need and want and what regulators require. For some, however, it does not go far beyond the status quo. Some think that it simply codifies -- or freezes -- the status quo. Many, frankly, are of the view, that the annex may well become an irrelevancy for most markets, as the tide of liberalization and competition sweeps past it.

On reflection, the annex is a useful benchmark of the minimum conditions for opening up a country's telecommunications sector for service suppliers. The telecommunications world has, in many respects, moved beyond it, or soon will do so. As noted below, however, that does not mean that the negotiations over the annex, or the annex itself, have not been worth the effort and will not have utility for the future.

D. Overall Assessment of the Uruguay Round, and its Implications for the Asia-Pacific Region

After five years of negotiations, it may almost be taken as facetious that it is still "too early" to assess the impact of the Uruguay Round on the telecommunications services sector. Nonetheless, with the outcome of the Round still uncertain, much work to do on negotiating the scheduled commitments in the request/offer process, and with the final text of the annex still not in place, it is difficult to render definitive views. Of course, by far the most critical factor for coming to some conclusions about the negotiations is how countries will, over the next few years, interpret the texts and fulfill their commitments.

With these caveats, however, I believe that

it was better to have the Uruguay Round than not and that the effort has been worth it. The dialogue between and among countries on the importance of telecommunications services has been unparalleled and invaluable. Other than the ITU, there had not previously been the opportunity for sharing information and exploring points of commonality and differences, on a multilateral basis. The bilateral negotiations among countries, or that have taken place on a regional basis, are no substitute for meaningful interaction among the broadest range of nations of significantly different levels of economic development.

In this regard, the negotiations have been an important forum for a dialogue between developed and developing countries on the impact of telecommunications services on national economies; telecommunications can be an engine for growth and efficiency, and ought not to be seen as a threat to a

1063

country's economic sovereignty.

Newly industrializing countries also played an indispensable and constructive role throughout the negotiations. Here, I have in mind, at least from this region, the documentation provided by both Singapore and Korea and their role in the discussions.

The GATS process also has contributed to a better understanding of the regulatory regimes in countries and to the identification of real barriers to trade in telecommunications services. For service providers and other users -- for carriers, providers of value-added services, and suppliers of the whole range of services that are critically dependent on telecommunications -- there is inestimable value in such transparency.

For the Asia-Pacific region, the dimensions of any long-term benefits from the Uruguay Round are uncertain. Having had the dialogue, of course, brings benefits to service suppliers throughout the region. The process has also been aspirational: countries on the path toward liberalization have a much better appreciation for what might be expected of them. They have more of an incentive to afford market access to service suppliers knowing that to do so will give them some access to other markets. The annex, for example, establishes the principles of access to and use of public telecommunications services, and countries can move to implement those principles in their own regimes.

For the most developed countries, and those furthest along the path toward competition and liberalization, the Uruguay Round process will not mean much in terms of their domestic agenda. For others, it has helped to deflect more focused bilateral pressures. For yet others, it will contribute to a sense that some liberalization of the telecommunications sector makes sense.

For all countries in the region, it is certain that the Uruguay Round, along with the free trade arrangements, the bilateral consultations and the IVANS arrangements, constitute a continuing challenge for all players in the telecommunications sector. It is not technology alone that challenges us. Nor is it economic pressures from customers. Rather, the challenge for many of us as we look toward regional integration in the telecommunications sector is how to create and use the legal and trade regimes that are the new framework for international telecommunications services.

THE PACSTAR OPTION - PAPUA NEW GUINEA'S INVITATION

PRESENTATION BY RON ELIAS
MANAGING DIRECTOR, POST AND TELECOMMUNICATION CORPORATION
PAPUA NEW GUINEA

at the

REGIONAL PACIFIC SYSTEMS SESSION 3.24

of the

PACIFIC TELECOMMUNICATIONS COUNCIL MEETING
15 JANUARY, 1992

IT GIVES ME GREAT PLEASURE TO BE ABLE TO ADDRESS THIS PACIFIC TELECOMMUNICATIONS COUNCIL MEETING AND PROVIDE YOU WITH INFORMATION ON THE PAPUA NEW GUINEA (PNG) INITIATIVE TO LAUNCH THE PACSTAR ASIA-PACIFIC REGIONAL COMMUNICATIONS SATELLITE SYSTEM.

I FEEL PROUD THAT I CAN EXTEND TO YOU, MY FRIENDS OF THE ASIA-PACIFIC REGION, AN INVITATION TO JOIN WITH PAPUA NEW GUINEA AS WE REACH THE CLOSING STAGES OF THE PACSTAR-1 SATELLITE PROJECT. YOUR PARTICIPATION IN THE PROJECT AT THIS TIME PROVIDES YOU WITH IMMEDIATE ACCESS TO PROJECT ASSETS, WHICH ARE WELL DEVELOPED AND AT NO COST TO THE NEW PARTICIPANT. I AM OFFERING TO ASSIST YOU WITH THE REQUIREMENT ASSESSMENT OF THE PACSTAR SPACE SEGMENT AT NO UP-FRONT COSTS AND WITHOUT CREATING ANY OBLIGATION FOR FUTURE USE OF PACSTAR.

THE DESIGN WORK AND MARKETING IS NEARING COMPLETION. THE RESERVATION COST OF LAUNCHING PACSTAR-1 ON THE SPECIAL LAUNCH VEHICLE HAS ALREADY BEEN PAID. MY GOVERNMENT HAS TARGETED THE IMPLEMENTATION OF THE PACSTAR SYSTEM FOR THE END OF 1994. WORLD BANK HAS ASSESSED THE PROJECT AND IS NOW PROVIDING FUNDING FOR THE 'PRE-INVESTMENT' STUDY, AN IMPORTANT ELEMENT OF THE PROJECT FINANCING.

WHY SHOULD MY COUNTRY BE SO INTERESTED IN THIS PROJECT?

TELECOMMUNICATION NEEDS IN PAPUA NEW GUINEA HAVE INCREASED IN RECENT YEARS WITH THE DISCOVERY OF EXTENSIVE MINERAL AND NATURAL RESOURCES IN REMOTE AREAS OF THE COUNTRY. THIS HAS IMPROVED HEALTH AND EDUCATIONAL OPPORTUNITIES AND INCREASED THE NEED FOR HIGHER PRIORITIES TO BE PLACED ON LAW AND ORDER PROBLEMS BY EXPANDING OUR LAW ENFORCEMENT TRAINING PROGRAMMES.

AS HEAD OF THE POST AND TELECOMMUNICATION CORPORATION WHICH HAS RESPONSIBILITY FOR MEETING THESE OBLIGATIONS, I HAVE BEEN PERSONALLY INVOLVED IN OUR EFFORTS TO IDENTIFY COST EFFECTIVE SOLUTIONS FOR EACH OF THESE DIVERSE NATIONAL OBJECTIVES. OUR CONCLUSION IS THAT DISTANCE SENSITIVE COMMUNICATION SATELLITES PROVIDE THE BEST TRANSMISSION MEANS FOR US TO ECONOMICALLY EXPAND OUR NATIONAL TELECOMMUNICATION NETWORKS WHICH REACH THE MOST REMOTE AREAS OF OUR LARGE ISLAND AND INTERCONNECTS WITH MANY OF THE 700 SMALLER ISLANDS THAT COMPRISE THE SOVEREIGN STATE OF PAPUA NEW GUINEA.

WE USE SUBMARINE CABLES AS WELL AS INTELSAT. IN FACT, WE ARE A MEMBER COUNTRY OF INTELSAT AND WE HAVE SERVED ON THE INTELSAT BOARD OF GOVERNORS. WE INTEND TO CONTINUE TO USE INTELSAT FOR SELECTED TYPES OF SATELLITE SERVICES. WE ARE ALSO USING PALAPA TO SATISFY SOME OF OUR DOMESTIC NEEDS. OUR RECENT ANALYSIS OF EXISTING COMMUNICATION SATELLITE SYSTEMS DEMONSTRATES CLEARLY THAT NONE OF THESE SYSTEMS CAN MEET ALL OUR TELECOMMUNICATION NEEDS IN A COST EFFICIENT MANNER. NEITHER CAN ALL OUR NEEDS BE MET BY USING TRADITIONAL TERRESTRIAL METHODS. THE MESSAGE IS LOUD AND CLEAR --- WE NEED PACSTAR TO CATER FOR OUR INCREASING TELECOMMUNICATION REQUIREMENTS.

FOR THESE REASONS, PTC, HAVING THE SUPPORT OF GOVERNMENT AND THE MINISTRIES OF FOREIGN AFFAIRS AND COMMUNICATIONS AND FINANCE INITIATED THE PACSTAR PROJECT SEVERAL YEARS AGO. SINCE THEN WE HAVE BEEN WORKING WITH CARRIERS LIKE TRT AND PACIFIC TELECOM AND PRIVATE ENTREPRENEURS TO IMPLEMENT THE PACSTAR SYSTEM AS A COMMERCIAL AND PRIVATE SECTOR INITIATIVE. THIS APPROACH HAS BEEN USEFUL AS WE HAVE LEARNED DIFFICULT LESSONS - LESSONS THAT HAVE DELAYED OUR PROJECT AND, I SUGGEST THAT OTHERS ON THIS PANEL ARE JUST BEGINNING TO BE AWARE OF.

THE RESULT OF OUR EXPERIENCE TO THIS TIME IS THAT, ALTHOUGH WE ARE STILL CONTINUING WITH OUR OBJECTIVE OF PACSTAR AS A COMMERCIAL PRIVATE SECTOR PROGRAMME, WE ARE WILLING TO STOP AT THIS POINT AND RISK PROCEEDING WITH THE PROJECT ON OUR OWN. SO AS TO ENFORCE THE DEGREE OF RESPONSIBILITY THE PACSTAR PROGRAMME IS HELD BY MY GOVERNMENT, MY CORPORATION HAS RECENTLY INCREASED ITS OWNERSHIP IN THE PROJECT TO A CONTROLLING LEVEL. PAPUA NEW GUINEA IS NOW TAKING THE LEAD IN DEVELOPING THE PACSTAR SYSTEM.

OUR DEVELOPMENTAL PLANS FOR USE OF THE PACSTAR SYSTEM TO THE END OF THE PRESENT DECADE SHOWS MY COUNTRY REQUIREMENTS ARE FOR TWO OR THREE PACSTAR TRANSPONDERS.

FROM THE COMMENCEMENT OF THE PROJECT WE HAVE CONSIDERED THE SATELLITE COMMUNICATION NEEDS OF OTHER ISLAND NATIONS; REGIONAL AND DOMESTIC BROADCASTERS; AND WORKING WITH OUR COUNTERPARTS WE HAVE CONSIDERED THE SMALL EARTH STATION NEEDS OF MULTINATIONAL USERS IN THE MORE DEVELOPED COUNTRIES OF KOREA, HONG KONG, SINGAPORE AND MALAYSIA.

A STRONG MARKETING EFFORT HAS BEEN LAUNCHED TO INFORM OTHER DEVELOPING COUNTRIES AND RECENTLY INDUSTRIALISED NATIONS, WITH LARGER TRAFFIC POTENTIALS BUT INSUFFICIENT TO JUSTIFY A DEDICATED SATELLITE SYSTEM, TO CONSIDER USING THE PACSTAR SYSTEM.

WE HAVE SPECIALLY STRUCTURED THE PACSTAR SYSTEM TO ENCOURAGE YOUR PARTICIPATION IN THE PROJECT AND SUBSEQUENTLY YOUR USE OF THE SYSTEM. LET ME EXPLAIN THE SYSTEM TO YOU.

FIRST, THE PACSTAR SYSTEM CONSISTS OF TWO HIGH POWERED COMMUNICATION SATELLITES WHICH WILL WORK INTO LOW COST, EASILY INSTALLED AND MAINTAINED EARTH STATIONS. THESE EARTH STATION NETWORKS ARE THE OPTIMAL WAY TO COST EFFECTIVELY DEVELOP TELECOMMUNICATIONS INFRA-STRUCTURES. THIS ALSO APPLIES TO REMOVE AREAS WITH LOW DENSITY TELECOMMUNICATION NEEDS SUCH AS IS EVIDENT IN MOST OF THE PACIFIC ISLAND NATIONS.

THESE TECHNICAL AND ECONOMIC ADVANTAGES OF THE PACSTAR SPACE SEGMENT ALSO ALLOW ATTRACTIVE NEW OPPORTUNITIES FOR PROSPECTIVE USERS IN THE MORE DEVELOPED COUNTRIES WITHIN OUR REGION BY MAKING NEW GROWTH SERVICE APPLICATIONS AFFORDABLE FOR THE FIRST TIME. THESE NEW GROWTH SERVICES BENEFIT END USERS BY IMPROVING THE QUALITY AND AFFORDABILITY OF NON-TRADITIONAL TELECOMMUNICATION SERVICES.

SECOND, TO ENSURE THESE SPECIALISED COMMUNICATION REQUIREMENTS, TWO ORBITAL POSITIONS WERE SELECTED AND, AFTER INTENSIVE TECHNICAL ANALYSIS A COVERAGE WAS OBTAINED OF THE EAST AND WEST RIM OF THE PACIFIC BASIN, THE ASEAN NATIONS AND THE SOUTH PACIFIC INCLUDING NEW ZEALAND AND AUSTRALIA. THAT WAS IN 1985.

NOW IN 1992, IN THE PACIFIC REGION, THERE IS A SEVERE CONGESTION OF THE ORBITAL ARC SO THAT IT IS NO LONGER POSSIBLE FOR COUNTRIES TO SECURE SUITABLE ORBITAL SPECTRUM WITHOUT INCURRING SUBSTANTIAL EXPENSE, IF AT ALL. PACSTAR OFFERS THE PACIFIC ISLAND NATIONS A POSITIVE SOLUTION TO THIS PROBLEM BECAUSE, UNLIKE OTHER PACIFIC REGIONAL SATELLITE INITIATIVE, THESE TWO OPTIMAL ORBITAL POSITIONS LOCATED AT 167.45 EAST LONGITUDE AND 175 WEST LONGITUDE, WERE OBTAINED LONG BEFORE THE CURRENT SCARCITY OF PACIFIC ORBITAL POSITIONS BECAME EVIDENT.

FURTHER LET ME SAY, THE INTERNATIONAL CO-ORDINATION PROCESS WHICH GENERALLY TAKES UP TO THREE TO FOUR YEARS, HAS NEARLY BEEN COMPLETED. THIS MEANS THAT WHEN NEW SATELLITES OR THE RE-POSITIONING OF EXISTING SATELLITES BECOMES NECESSARY, THE COUNTRY CONCERNED ***MUST*** ENSURE THAT THESE DO NOT INTERFERE IN ANY WAY WITH THE TWO PACSTAR SATELLITES. THIS IS A TREMENDOUS ECONOMIC, TECHNOLOGICAL AND OPERATIONAL ADVANTAGE TO PAPUA NEW GUINEA AND TO ANY OTHER NATION THAT JOINS THE PACSTAR PROJECT.

THIRD, IN ADDITION TO THE TECHNICAL ADVANTAGES OF THE HIGH POWER OF THE PACSTAR TRANSPONDERS AND THE OPPORTUNITY TO USE THE PERFECTED ORBIT SPECTRUM, THE REVENUE POTENTIAL FOR TELECOMMUNICATION AUTHORITIES AND BROADCASTERS TAKING PART IN THE PACSTAR PROJECT IS EVIDENT. IN ADDITION, THE LOW COST EARTH STATIONS WHICH ARE USABLE WITH PACSTAR, AND NOT WITH ANY OTHER SATELLITE SYSTEM, GIVE TELECOMMUNICATION AUTHORITIES AND BROADCASTERS NEW BUSINESS OPPORTUNITIES IN EDUCATIONAL AND COMMERCIAL BROADCASTING. PACSTAR CREATES SIGNIFICANT NEW REVENUE OPPORTUNITIES FOR THOSE WHO PROCURE A PACSTAR SPACE AND CONTROL ACCESS TO THE EARTH STATION FACILITIES.

FINALLY, AND POSSIBLY THE MOST ATTRACTIVE FEATURE IS THAT PACSTAR IS NOW IN THE FINAL STAGE OF DEVELOPMENT. WE HAVE COMPLETED THE PACSTAR-1 SATELLITE PERFORMANCE SPECIFICATION AND HAVE SUBMITTED IT TO SEVERAL MANUFACTURERS. WE USE APRIL FIRST OF THIS YEAR AS THE TARGET DATE FOR PROCUREMENT UNDER A PRIORITY SCHEDULE SO THAT WE CAN ACHIEVE OUR LAUNCH DATE OF 1994.

THE BOTTOM LINE IS THAT PACSTAR-1 WILL BE IN ORBIT BY THE END OF 1994 AND COMMERCIALLY OPERATIONAL BY EARLY 1995. THE TECHNICAL WORK OF CUSTOMISING THE PACSTAR TRANSPONDERS AND THE CONFIGURATION OF THE PACSTAR-1 SATELLITE MUST BE ENTIRELY COMPLETED WITHIN THE NEXT FEW MONTHS.

I EXTEND TO YOU AN INVITATION TO JOIN US IN IMPLEMENTING THE PACSTAR PROJECT NOW AND CAPTURING AND SHARING THE BENEFITS WHICH WILL BE ENJOYED BY PAPUA NEW GUINEA, THAT IS, A CUSTOMISED TRANSPONDER AT COMPETITIVE PRICES, THE USE OF A WELL DEVELOPED SATELLITE AND LAUNCH VEHICLE, ACCESS TO PRIORITY ORBIT SPECTRUM RESOURCES, TECHNOLOGY TRANSFER BENEFITS AND LOTS MORE.

I LOOK FORWARD TO DISCUSSING THIS PROJECT WITH YOU DURING THE REMAINDER OF THE CONFERENCE --- THANK YOU.

THE IMPORTANCE OF OPEN MARKETS IN INTERNATIONAL TELECOMMUNICATIONS TRADE

REMARKS BY

ALLEN R. FRISCHKORN, JR.

PRESIDENT

TELECOMMUNICATIONS INDUSTRY ASSOCIATION

AT

THE 14th

PACIFIC TELECOMMUNICATIONS CONFERENCE

JANUARY 15, 1992

HONOLULU, HAWAII

1070

I very much appreciate the opportunity to appear here today to talk about the importance of open markets to worldwide trade in telecommunications. Obtaining greater access in foreign telecommunications equipment markets is one of the priorities of the Telecommunications Industry Association.

The Telecommunications Industry Association is a full service national trade association representing around 500 manufacturers and suppliers of telecommunications equipment. TIA member companies manufacture or supply virtually every product used in today's telecommunications network. Our members are competing for business in the world market for telecommunications products. Accordingly, they are very concerned about fair competition.

TIA and its member companies are committed to working for open telecommunications markets around the world. Telecommunications has been recognized as a necessary prerequisite to economic growth and, as such, is a critical ingredient for developing countries seeking to "jump start" their economies as well as for developed countries which are seeking to enhance their competitiveness in an increasingly global

EDSU

marketplace. To encourage telecommunications manufacturers around the world to produce the most sophisticated products possible at the least cost requires free and fair competition in telecommunications equipment in every market. Enhancing market access opportunities abroad to match the openness of the U.S. market is therefore a fundamental goal of TIA.

There can be little doubt that the U.S. market is open to free and fair competition in telecommunications equipment. FCC deregulatory actions over the past twenty years coupled with the divestiture of the Bell Operating Companies by AT&T have created a huge open market for telecommunications products. Foreign telecommunications manufacturers are very active in the U.S. market. All of the major foreign telecommunications producers now manufacture in the U.S. and are doing steadily increasing business with the Bell Operating Companies and other telephone companies.

While the U.S. market is open, U.S. telecommunications equipment manufacturers face less than an open market abroad. Foreign

government buy-national policies, cultural preferences and other non-tariff barriers have effectively precluded U.S. companies from achieving comparable competitive opportunities in many countries. Meanwhile foreign company penetration in the U.S. market has been steadily increasing.

I'd like to take a moment to explain why market access is so important. Because of the high cost of developing state of the art telecommunications products, economies of scale are crucial for success in the telecommunications equipment business. It doesn't take a PhD in economics to figure out that if our competitors have a monopoly in their home market coupled with free access to our market, and we only have access to our market, all things being equal our competitors will win out in the long run. U.S. companies need access to our major competitors' markets to subject such competitors to the rigors of price competition. Such competition will force the prices of our competitor's products towards their costs, thereby eliminating the monopoly profits which can be used to undercut U.S. suppliers in third countries or in the U.S. market. In other words, only free and open competition will assure

1032

U.S. manufacturers a level playing field in the world telecommunications marketplace.

While these goals seem self evident, free and fair competition in telecommunications equipment in many markets is illusive. Many countries do not revere the free enterprise marketplace as we in the United States do. The countries of particular concern in terms of market access are those with large internal markets that export substantial amounts of telecommunications equipment to the United States. These countries include Japan, Canada, EC countries and Korea.

Historically, U.S. producers have been locked out of the Japanese market. However, the U.S. and Japan have entered into two major agreements over the past ten years designed to open up that market.

The first agreement – the so-called NTT agreement – was designed to open up the then government owned telephone monopoly to U.S. suppliers. Under the agreement, U.S. companies have sold over $1.5 billion of equipment to NTT since 1981. Sales over the past 2 years have

1033

been increasing by a larger percentage than previous years. I believe that this is due in large part to the efforts of top NTT management. Despite this progress, however, the U.S. share of the NTT market continues to hover around only 4%. We will continue to work with NTT in the hope that U.S. company participation in the NTT market -- still by far the largest telecommunications equipment market in Japan -- continues to increase.

In 1985, the U.S. and Japan entered into "market oriented, sector specific" or "MOSS" agreements. These agreements were designed to give U.S. manufacturers greater access to the customer premises equipment and radio equipment markets in Japan. While some progress has been made under the MOSS agreements, a number of problems have arisen including a major problem involving Motorola's access to lucrative cellular frequencies. This problem was resolved satisfactorily in 1989. More recently, the U.S. and Japan reached agreement on telecommunications issues involving satellite procurement, digital terminal equipment and value added networks. Discussions are now in progress concerning increased access to the Japanese government

1034

procurement market. While all problems haven't been resolved progress is being made.

Finally, deregulation in Japan has spawned a whole new group of carriers called the New Common Carriers or "NCC's". These competitors to NTT have created additional business opportunities for U.S. companies. U.S. companies are taking advantage of these opportunities and sales to this new group are growing steadily. Since Japan still accounts for the great bulk of the U.S. trade deficit in telecommunications – $1.8 billion during 1990 – they will remain a major focus of our market access efforts.

In Europe, many markets have been closed to U.S. manufacturers unless the U.S. companies set up in-country manufacturing operations. Historically, most European countries have buy-national policies designed to protect jobs in the domestic economy. That has been changing more recently in a number of countries.

1955

The United Kingdom, for example, has one of the more open markets in Europe for telecommunications equipment. In the last several years both the French and Germans have begun to liberalize their telecommunications markets. We have worked with the French and Germans and have encouraged them on these actions. It is still too early to tell whether these liberalization measures will take hold and whether real sales opportunities will be created for U.S. manufacturers.

We have also been working closely with the European Community (EC) in Brussels on its 1992 single market initiative. During the course of its 1992 activities, the EC has issued a number of directives on telecommunications, including directives on procurement, standards, and type approval of interconnect equipment.

We have some concerns about the EC procurement directive since it includes a buy-European provision. However, the elimination of intra-EC barriers will enable U.S. companies manufacturing products in Europe, to access the entire EC telecommunications equipment market. We will be watching as the EC countries implement the procurement directive.

1036

In the meantime, there is an effort underway in the GATT round to bring PTT's, including the European PTT's, under the Government Procurement Code. If that happens, U.S. companies will receive national treatment for purposes of telecommunications procurement.

Our association has begun to work with the European telecommunications Standards Institute ("ETSI") to coordinate our standards activities with those of that organization. We are hopeful that the ETSI process will be open and transparent and that the standards setting process will no longer be used as a barrier to market access.

The EC type approval directive is now being implemented by EC member countries. It should simplify and harmonize the various type approval requirements in EC countries thus allowing equipment approved in one EC country to be sold in other EC countries. We will be watching to see how individual countries implement the directive.

The market access problem in Canada stems from the fact that Bell Canada is vertically integrated and buys virtually all of its equipment

from its affiliated supplier under a "preferred supplier" arrangement. Since Bell Canada is over 60% of the Canadian telecommunications equipment market, U.S. manufacturers are effectively shut out of the biggest part of that market. Efforts were made by the U.S. government to end the Bell Canada preferred supplier arrangement during the U.S./Canada free trade negotiations. Those efforts were unsuccessful but the issue remains an irritant in the U.S./Canada trade relations.

The U.S./Canada free trade agreement makes some improvements for telecommunications trade between the two countries. Prior to the agreement, tariffs on any telecommunications equipment exported from the U.S. to Canada were about twice as high as those on equipment shipped to the U.S. from Canada. The agreement provides for accelerated elimination of tariffs on some equipment with the elimination of all tariffs over ten years. The tariff changes will result in additional opportunities for U.S. companies in Canada. However, unless the Bell Canada preferred supplier problem is resolved the biggest part of the Canadian market will still remain off limits for U.S. telecommunications equipment manufacturers.

1033

With respect to Korea, U.S. companies have been concerned for many years with the Korean government's buy-national policies with respect to all of its telecommunications needs including the procurement of then KTA. Moreover, there was a suspicion that the standards and the equipment approval process for interconnect equipment was being used to discourage the import of telecommunications equipment. This was of particular concern to U.S. manufacturers since Korean telecommunications exports to the States have grown dramatically over the past several years to a high of nearly half a billion dollars in 1990.

Because of all of these market access concerns of the U.S. industry, TIA and its member companies lobbied the U.S. Congress for tough legislation to open up foreign telecommunications equipment markets. These lobbying activities culminated with the passage of the Omnibus Trade and Competitiveness Act of 1988. That legislation contained telecommunications market access provisions which were designed to address foreign barriers to U.S. telecommunications equipment manufacturers.

1083

Specifically, the legislation authorized the President to identify the countries which did not give U.S. telecommunications equipment suppliers reciprocal market opportunities. Once those countries were identified, the President was authorized to commence negotiations to remove trade barriers and to increase the market access of U.S. manufacturers. If such negotiations are unsuccessful, the President was further authorized to take retaliatory action against products entering the U.S. from the offending countries.

Subsequent to the passage of the legislation, the European Community and Korea were identified as countries which did not give reciprocal market access opportunities to U.S. companies. Negotiations were begun with those countries in 1989 and are still in progress. In addition, other provisions in the legislation provided for the annual review of agreements previously negotiated with Japan and other countries to determine whether they are being complied with.

Although all market access problems with these countries have not been resolved, substantial progress has been made.

1000

In Europe, the EC'92 initiative will eliminate many trade barriers among European countries in the telecommunications sector. American companies which operate in Europe will be able to take advantage of intra-EC telecommunications liberalization. However, as mentioned earlier, exports from the U.S. will still be subject to a buy-European preference. This issue is the focus of the continuing negotiations with the EC to have American exports treated the same as exports among E.C. countries. Since certain of the U.S.-E.C. telecommunications issues are similar to issues being considered under the GATT Government Procurement Code, the procurement part of the U.S.-E.C. telecommunications negotiations have been rolled into the GATT Round. We are hopeful that those negotiations will ultimately result in a resolution of the telecommunications trade issues. However, if they are not successful, the U.S. must consider its options, including retaliation, to rectify the competitive imbalance.

With respect to Korea, negotiations on telecommunications manufacturing issues have gone very well. The Koreans have announced plans to open the procurement of Korean Telecom to U.S.

10.1

companies over a two year period beginning in 1992. Under the procurement changes, U.S. companies will not be discriminated against when bidding for business with Korean Telecom.

Just this month, we were visited by a Korean delegation which explained a number of changes taking place in telecommunications in Korea. Based on that presentation, it appears that many of the problems in the areas of procurement, standards and type approvals are being satisfactorily addressed. We had hoped that Korea would put its telecommunications procurement under the government procurement code of the GATT round. However, at the present time, it is unclear how the GATT procurement discussions will proceed. Nevertheless, the commitment of the Korean government to open up telecommunications procurement will be implemented on a bilateral basis over the next two years. TIA will be working closely with Korea Telecom and the Korean government as this process moves forward.

In my view, the GATT negotiations offer an opportunity for us to obtain an agreement which will open up telecommunications authorities

1032

worldwide to competitive procurement for the first time. Under the Government Procurement Code, countries participating agree to treat companies from other signatory countries the same as their own companies for purposes of government procurement. Since telecommunications authorities are government owned in most countries, extension of the Code to PTT's would open up their procurement to U.S. manufacturers. We hope that the issues delaying progress in the GATT are resolved and that negotiations move ahead to resolve the outstanding difficult telecommunications issues under the Government Procurement Code. However, if the GATT government procurement discussions break down, the U.S. will pursue its market access goals on a bilateral basis.

The creation of an open system of telecommunications procurement worldwide has advantages for everyone. Under such a system, decisions on which equipment to purchase will be made on the basis of price, quality and service rather than on the nationality of the seller. This will assure that the purchaser gets the best product at the best price. Consumers of telecommunications service will not have to pay for

1093

inefficiencies in the manufacturing process. Manufacturers will have to compete on the basis of price, quality and service. The efficient will prosper and the others will fall by the wayside. Finally, eliminating protection barriers will remove a major trade irritant among the nations of the world. Resources now devoted to resolving trade disputes can be shifted to more productive uses such as promoting the development of telecommunications in developing countries where such development is essential for economic growth.

In summary, market barriers still exist in many countries. Since the U.S. market is open, the U.S. industry must eliminate foreign trade barriers to remain competitive. The U.S. industry and the U.S. government are working hand in hand, both bilaterally and multilaterally, to bring about a fully competitive world market for telecommunications equipment. Such a market has many advantages for consumers, telecommunications service providers and manufacturers. A major source of trade friction could be eliminated and government and private resources now devoted to market access battles, could be put to more productive uses.

Thank you for your attention. I'd be happy to answer any questions you may have.

1035

COMPETITION AMONG SATELLITE SYSTEMS AND THE CREATION OF NEW COMMUNICATIONS MARKETS

by Douglas Goldschmidt & Philip Rubin
Alpha Lyracom Space Communications

The Pacific Rim nations are about to experience a significant increase in the availability of satellite facilities. While the area is currently served only by Intelsat, AsiaSat, and to a limited extent, by domestic satellite systems in Japan, Indonesia, and China, there will be an increase in service availability over the next three years due both to the expansion of existing systems, particularly Palapa and possibly Aussat, and the introduction of new specifically competitive services by Alpha Lyracom, Columbia Communications, and possibly one or two other satellite systems. The increased capacity and the new competition will have dramatic effects on the type, range and price of communications services in the Pacific Rim.

Alpha Lyracom and Latin America

To a large degree, the availability of satellite services in the Pacific Rim is similar to the historical situation in Latin America. Prior to the PAS-1 launch in 1988, Latin America had few satellite services available to it. Brazil and Mexico have had their own satellite systems for some years, but these were purely for domestic communications and offered few services to neighboring countries. Other countries utilized leased Intelsat capacity primarily for domestic telephone services. Intelsat's services were optimized for international connectivity among gateway stations and were poorly designed for any applications requiring multiple uplinks and downlinks, such as domestic video distribution or business communications. Furthermore, the Intelsat signatories charged exorbitant amounts to potential national users. The high cost of using Intelsat was reflected by the low level of demand for Latin American satellite services -- there was no projected full time video traffic for the region in the Intelsat GTM prior to 1988, and extremely modest amounts of IBS.

Alpha Lyracom's entry into the Latin American market had an enormous affect on market demand and supply. Aside from the supply its satellite introduced to the market, Intelsat, as a competitive response to PAS-1, modified its VB satellites to offer higher powered domestic services. Hence, Latin America, which previously had no high powered services, by 1988 had two satellites offering the type of performance usually associated with domestic satellite systems.

1096

More importantly, as a new competitor, Alpha Lyracom actively and aggressively marketed its transponders for domestic services, and for regional data and video services. It was the *combination* of new supply with direct marketing to consumers, bypassing the conservative national telecommunications administrations, which led to dramatic changes. For, once users found that they could get services superior to those offered by their local telephone companies using Intelsat capacity, and more importantly, at lower overall costs, the political pressure for liberalization became uncontrollable. And, as the pressure to liberalize grew, the PTT's themselves became more interested in providing services appropriate to the users.

The results have been impressive. In 1988 there were *no* regional video networks. Today there are seven full time regional networks, and a number of part time news and sports networks on PAS-1. In 1988 there were no private domestic satellite based networks. Today there are networks in Chile, Argentina, Venezuela, and Peru which all use PAS-1 spot beams. And, far more networks would exist if Alpha Lyracom had more capacity. Similarly, we are seeing the rapid development of private data networks, with faster developments possible if local regulations were more liberal than at present.

The key to this discussion is not simply Alpha Lyracom's success in introducing its satellite service, but in the effect that competition had on the overall market. As any economist would predict, competition has markedly lowered prices, increased diversity, and increased the overall market size. Not only is Alpha Lyracom's full time dedicated video capacity completely sold out in Latin America, but so is Intelsat's dedicated domestic capacity, and Intelsat is facing a capacity shortage. Future entry has been expanded not only by Alpha Lyracom's, Intelsat's, and Brazilsat's new series of satellites, projected to be launched in 1994/95, but by capacity on the new Mexican Solidaridad satellites and Spain's Hispasat.

Developments in the Pacific

There are a number of satellite systems under development in the Pacific. For obvious reasons (our competitors can speak for themselves), I will focus on Alpha Lyracom's two Pacific oriented satellites: the ORBX-2 and ORBX-4.[1]

Alpha Lyracom recently signed an agreement with Hughes Communications for the construction of three new satellites using the Hughes HS-601 3-axis stabilized satellite bus.

ORBX-2 will be stationed at 192° WL, while ORBX-4 will be stationed at 72° WL.[2] ORBX-2 is designed to offer Trans Pacific coverage, going as far west as Thailand and as far east as California. It will also offer transponders for regional and domestic communications services, in C band and Ku band, throughout the Pacific Rim. Importantly, ORBX-2 will offer high powered footprints of the Pacific Islands. ORBX-2's footprint is shown in Figure 1.

ORBX-4 is designed primarily for service to central Asia, Africa, and eastern Europe. However, it will offer connectivity between the United Kingdom in the West and Japan in the East. The satellite will thus, link the Pacific Rim nations to Europe and Central Asia, the only satellite to offer such an extensive range of coverage. ORBX-4's draft footprint is shown in Figure 2.

The three new ORBX satellites will be C/Ku Band hybrids with thirty-two operating transponders, sixteen in each band. The C band transponders will utilize 30 watt amplifiers, while the Ku-band transponders will utilize 63 watt TWTA's. The ORBX satellites will be the first FSS satellites to utilize a new technical approach to generating footprints that follow the desired coverage area boundaries with a unique precision. This new technical approach has the potential to reduce satellite weight and complexity, improve spacecraft EIRP and G/T, and improve reliability. The design will replace the multiple feedhorn design of today's spacecraft and result in reduced satellite costs and lower transmission losses in addition to the benefits desribed earlier. Each ORBX satellite will produce up to fourteen separate beams using this technology, which will be the conerstone of the satellite's technical capability.

ORBX will also have the ability to switch certain transponders between beams. This will allow the rearrangement of satellite capacity as the market dictates. With cross-strapping and transponder switchability, no area is uncovered, and certain areas will have the flexibility to increase traffic capacity in areas requiring such growth.

The ORBX spacecraft will have from upwards of fourteen years to as many as twenty-five years of life, depending on the launch vehicle selected. Negotiations are currently underway with a number of launch vendors, and a launch reservation has already been make with the Chinese Long March.[3]

The ORBX communications payload has been expressly designed to facilitate the transmission of digital carriers. While analog traffic would not be excluded, the satellite will operate most efficiently when digital traffic

1035

occupies any transponder. As such, each transponder includes a linearizer within its general design allowing multi-carrier operation at the highest operating point possible. While nominal transponder bandwidth has been set at 54 Mhz, each spacecraft will have two transponders with wider bandwidths available to accommodate higher rate digital carriers.

The ORBX Satellites and Service Offerings to the Pacific Rim

To date, the Pacific Rim's services have either been through the "conventional" Intelsat services, offered on aged capacity, or on domestic satellites with limited coverage. The launch of the Intelsat VII series will not have a significant effect on regional communications as Intelsat's orientation remains international, rather than to the particular needs of a region or nations. And, more importantly, Intelsat's relationship with its signatories significantly hinders its ability to respond in a competitive way to user requirements.

AsiaSat has offered an important new service to the region, but its capacity is both limited in quantity and scope -- it only offers C-band service. Columbia will only be able to offer medium powered C-band service for Trans Pacific service. And, the other proposed Pacific satellite systems have failed to attract the necessary investments to date to initiate construction.

Alpha Lyracom is irrevocably committed to the ORBX system -- the construction contract has been signed and the financing is in place. Construction on ORBX-2 has already begun. The satellite's launch in 1994 will immediately introduce direct competition with Intelsat for international video and digital services, and with Intelsat and AsiaSat for regional and domestic video and digital services. Competition with national satellite systems will be less direct as we assume that national systems will dominate in their respective territories.

Rather than simply entering the market as another provider of satellite capacity, Alpha Lyracom intends to promote a series of innovative services which are either incipient or not offered at all in the region. In particular, we intend to offer:

- compressed video for entertainment and news distribution. By moving away from analogue transmission we anticipate drops in video networking costs of approximately 60% by 1995. And, by integrating compressed video with dynamic transponder allocation technologies, it will be possible to provide "instant" transmission

services to meet the requirements for special events and news services.

- multipoint integrated digital networks utilizing mesh TDMA and SCPC technologies for domestic and regional telecommunications. Moving away from hub systems and from fixed assigned systems will greatly improve the quality of digital systems and, more importantly, will improve their flexibility while dramatically reducing their cost.

- on-demand bandwidth services to meet the changing requirements of businesses for voice, data, and videoconferencing applications.

We expect that both introducing Alpha Lyracom's capacity and the services will have an enormously stimulating affect on regional communications. The most immediate effect will be on regional and domestic video -- the high powered satellite signal tied with the introduction of digital compression will help jump start regional and domestic video networking for entertainment, news, and business. The competition to provide different types of digital services will similarly stimulate the development of integrated digital systems to augment and, in some cases compete, with the domestic terrestrial networks. If Latin America is any example, the following can be expected:

- video networking costs will drop by about 60% over current costs;

- international digital transmission costs will drop by over 50%;

- digital networking costs will edge downwards, with a probable decrease of 25% within two years of increased competition;

- existing suppliers, notably Intelsat, AsiaSat, and possibly some of the domestic satellite providers, will react strongly to the competition, further reducing satellite transmission prices and end user prices. More importantly, services will be tailored around user requirements rather than around the dictated services now offered by monopoly service providers.

1. There are four satellites in the ORBX series: ORBX-1, formally known as PAS-1, which currently provides service to Latin America and between the U.S. and Europe, ORBX-2, which will cover the Pacific Rim, ORBX-3, which will augment ORBX-1's coverage, and ORBX-4, which will cover the Indian Ocean Region.

2. ORBX-3 will be positioned over the Atlantic Ocean at 39.5° WL for Atlantic Ocean Region services.

3. The Long March may be precluded by U.S. restrictions on exports of high technology equipment to China.

REGULATION OF WIRELESS COMMUNICATIONS - THE NEED FOR REFORM
AN AUSTRALIAN PERSPECTIVE

A paper by Dr John Griffiths and Ian Cunliffe, Partners,
Blake Dawson Waldron,
Sydney, Australia.*

14TH PACIFIC TELECOMMUNICATIONS CONFERENCE
SHERATON WAIKIKI HOTEL, HONOLULU, HAWAII
JANUARY 12-15 1992

ABSTRACT

This paper examines the recent flurry of activity in Australia to bring about radical reform of management of the radio frequency spectrum which will affect both telecommunications and broadcasting in significant ways. The general thrust of the reform proposals is to move towards a market based system for allocating frequencies, but this is likely to happen more gradually than was the case in New Zealand.

BACKGROUND

The last few years have seen a rash of inquiries into Australia into management and allocation of the radio frequency spectrum by a Federal Parliamentary Committee (the House of Representatives Standing Committee on Transport Communications and Infrastructure), the Bureau of Transport of Communications Economics and the Department of Transport and Communications.

Such inquiries are a response to revolutionary technological changes which are occurring in the communications industry and the unprecedented pressures being applied to the spectrum as a finite resource. The plethora of inquiries is doubtless also a reflection of the influence of free market ideology on public administration.

Twenty years ago demand for the radio frequency spectrum was much less than it is today, and it principally came from the public sector (eg Defence, Post Master General's, Civil Aviation, Maritime Surveillance/Search and Rescue and other transport uses), and from heavily regulated private sector industries like television and broadcasting, plus two way voice radio users.

Today those all continue to be important uses. But they have been joined by new uses - the ubiquitous portable telephone, new information and entertainment services, including video and audio entertainment and information services such as Sky Channel and various forms of non-broadcast radio, and FM radio (which made its Australian appearance in 1974). In the last ten years in Australia we have seen State Governments moving to build their own communications networks, partly using the radio frequency spectrum.

MOBILE COMMUNICATIONS, WIRELESS LANS AND OTHER NEW USES OF THE RADIO SPECTRUM

On the horizon is an enormous boom in mobile communications both of data and voice. By the end of this century, we are likely to have very extensive personal communications networks: instead of having telephones attached to wall sockets at home and at work, and a mobile phone in the car, many people will have a small handset the size of a dictaphone and just as portable which will interact with the PABX at work, but which will also be used at home or on the move. Similarly we will see the early introduction of systems which enable fixed and mobile computers to communicate with one another both in local areas and over wide areas, but without the costs and inflexibility and lack of mobility which come with a totally wired network. The proponents of these new uses of the radio frequency spectrum are principally in the private sector. The users of them will be in all sectors of our community. Governments will be very heavy users.

These new uses and users have put and will put increasing demands on the radio frequency spectrum. In Australia, the amount of radio spectrum which is available for use at any one time is limited by a number of factors:

- the complex design of radiocommunications equipment and the impracticality of Australia departing from International standards gives Australia little choice in some frequency bands. We generally follow Europe and North America;

- broadcasting is a major user of radio frequency spectrum, especially in the valuable area below 1000MHz. This effectively limits the amount of spectrum available for other radiocommunications users;

- the extent to which the spectrum may be used is limited by the available technology; and

- use of one segment of the radio spectrum may cause interference in another segment.

However the picture is not entirely one of increasing demands on a static resource. Although the radio spectrum is a finite resource, it does not follow that it has a fixed capacity to transmit information. Engineering advances have opened up new parts of the radio frequency spectrum, and many of the new users are accommodated in those parts of the spectrum. Additionally, engineering advances have greatly increased the efficiency of use of the existing spectrum - both through frequency reuse techniques, so that the same part of the spectrum can be reused again and again even within very small geographic areas, and through techniques such as digitalisation which allow a much greater volume of information to be transmitted through the same radio channel as previously. Furthermore, in Australia we have traditionally taken a very conservative approach to allocation of the frequency in order to avoid possible interference between different users. There is possibly scope to be a little less conservative.

The other influence causing a re-examination of the way we allocate frequency is a loss of faith in the ability of Government regulators to allocate scarce resources, and the converse love affair we had during the 1980s with the free market. That love affair lingers though the flame flickers less brightly. The notion that the free market is the best way to allocate scare resources has been a strong influence in the adoption of the auction system of allocating frequency spectrum in New Zealand, and was a heavy influence on the report of the Australian Bureau of Transport and Communications Economics into the Management of the Radio Frequency Spectrum.

WHAT IS THE CURRENT SYSTEM OF MANAGEMENT/REGULATION OF THE RADIO SPECTRUM IN AUSTRALIA?

The management of the radio spectrum is an exclusive Commonwealth responsibility under section 51(v) of the Commonwealth Constitution. The Constitution also empowers the Commonwealth to legislate for external affairs, which provides a basis for the application of international conventions to spectrum management.

NATIONAL MANAGEMENT

The Australian system of management radio spectrum is principally one of licensing by the Government for a specific use over a specified period. The licensing system is regulated through the operation of two Acts:

- The *Radiocommunications Act 1983* administered by the Minister for Transport and Communications using the Department as a national spectrum planning authority;

- The *Broadcasting Act 1942* administered principally by the Australian Broadcasting Tribunal.

The Minister's role under the *Radiocommunications Act* (the *"Radcom Act"*) is to facilitate the use of the radio spectrum through the issue of licences on a first come first served basis. While licences can be cancelled or not renewed, the practice has been that once issued they are seldom terminated.

There have been interesting developments in recent months in the use of Frequency Reservation Certificates (FRCs). Under s.21 of the *Radcom Act*, it is possible to reserve frequency assignments usually for a period of 12 months for future uses and, thus, provide an environment in which investment can be undertaken with the knowledge that a certain frequency is reserved and will not be assigned to someone else. The holder of a FRC has a guarantee that so long as the certificate remains current no other person will be assigned that frequency for any use that would prohibit the use of the reserved frequency. FRCs are not licences and do not authorise transmission on the reserved frequency. In addition, the issue of a FRC gives no guarantee that the person who holds the certificate will ultimately be granted a licence. One drawback with FRCs is that under the Department's administrative arrangements, frequencies covered by an FRC cannot be assigned to new users in the event that demand exceeds the assignment availability in that band. The Department has recently moved to address this problem and new guidelines have been approved which restrict the holding of FRCs in trunked land mobile spectrum where continuing network development is not evident. Current experience is that if you obtain an FRC it only lasts for one year and there is no obligation on the Department to renew the reservation. If after that time, the system is not "operational", the Minister may cancel the certificate. The Minister therefore has a discretion

If we are to auction spectrum, when do we do so? Should we auction it off all at once? Or should we only auction off those parts that seem to be in immediate demand? Is auctioning just an attractive way of raising public revenue while abrogating wider public responsibilities?

Especially given the revolutionary developments which are taking place in communications - for example the ability for one computer to transmit data to another via radiocommunications, the ability to use parts of the spectrum which previously were unusable, and increases in efficiency of spectrum use through new digital techniques, and the like - the analogy with land tends to break down. The uses we can make of land tend to change only slowly over time. The uses we can make of the radio frequency spectrum change very quickly and very dramatically. An auctioning approach would not be sophisticated enough to encourage innovative use of the radio frequency spectrum. Rather it could tend to entrench established players, and could tend to militate against innovation. Enthusiasm for the market needs to be tempered by responsive regulators ensuring that the radio frequency spectrum is used in the public and as well as the private interest.

REFORM OF AUSTRALIAN SPECTRUM MANAGEMENT

There is considerable interest at present in Australia in the need to reform existing arrangements for managing and allocating radio frequency spectrum. In late 1990, the Bureau of Transport and Communications Economics ("BTCE") published a major report on the subject and recommended the introduction of a market-based system to replace the current radiocommunications assignment system. The proposed system would have the following features:

- the creation of Spectrum Access Rights ("SAR's");
- open trading in SAR's (i.e. turning the spectrum into a marketable commodity);
- holders of an SAR would be free to alter the technical parameters, the number of services and uses within the spectrum package, provided they do not exceed the stipulated conditions related to interference;
- auctioning of SAR's, where appropriate;
- in other cases, SAR's would be available over-the-counter at a charge consistent with efficient pricing principles; and
- other charges would be applied to users on a cost recovery basis.

In November 1991, in its report entitled "Economic Aspects of Broadcasting Regulation", the BTCE echoed its earlier report and recommended a number of fundamental changes to the regulation of Australian broadcasting, including:

- the introduction of a system allowing broadcasting spectrum access rights to be bought and sold;
- unrestricted entry to various broadcasting markets, involving the elimination of artificial restrictions on entry, such as commercial viability tests;
- allowing broadcasters greater freedom in choosing the technology or mode of delivery for their services, but obliging them to provide technically adequate signals throughout pre-defined service areas.

Some, but not all these proposals have been subsequently incorporated in the exposure draft of the new Broadcasting Services Bill (see below).

PARLIAMENTARY INQUIRY INTO MANAGEMENT OF THE RADIO FREQUENCY SPECTRUM

The House of Representatives' Standing Committee on Transport, Communications and Infrastructure has recently conducted an Inquiry into Management of the Radio Frequency Spectrum and the need for reform. The Committee received various written submissions, including a major submission from the Department of Transport and Communications. The Committee's October 1991 report is likely to be seen as a blueprint for the future direction of its subject matter in Australia.

The Committee concluded that the current approach in Australia to spectrum management is deficient with respect to:

- Dynamic efficiency: current spectrum management practices lack flexibility and timeliness with regard to changing demand for spectrum use;

to shift potential users out of the radio spectrum if the frequency is not utilised after a period of one year. Under s.86 of the *Radcom Act* such a decision by the Minister is a "reviewable decision" and an application may be made to the Minister to reconsider such a decision and, if necessary, to the Administrative Appeals Tribunal ("AAT") which can conduct a full merits review of the decision. Initial planning decisions, including those refusing to grant an FRC or licence are not currently reviewable by the AAT.

The House of Representatives Standing Committee on Transport Communications and Infrastructure recently recommended that the use of FRCs be discontinued and that users wishing to reserve spectrum should be issued with a licence after submitting a plan which outlines the timescale for full utilisation.

The *Radcom Act* gives essential power to the Government in the long term to reorder the radio spectrum for new priorities and to raise spectrum productivity. The Minister has the authority to publish overall plans for the use of the spectrum in the Spectrum Plan, which is based on the International Table of Allocations. The National Spectrum Plan provides a strategic national overview of the uses for each band within the spectrum. It is regularly revised to reflect any changes in the international arena, variation in strategies agreed to by Government in the national arena and technical developments.

Band Plans further partition the allocations defined in the Spectrum Plan and specify particular services which may be licensed and their relative priority within each band. In Australia, these Band Plans define the limits of each frequency band, and also provide the basis for the development of the rules for sharing and allocating frequencies between users and uses.

Spectrum planning in Australia determines:

- the uses for a particular band;
- the bandwidth and separation between channels; and
- the technical parameters of transmitters and receivers and whether channel sharing is to be permitted.

The management of the radio spectrum at a national level is constrained by a number of factors:

- the large capital investment required for communications networks, including equipment means that users require some form of guaranteed access to the spectrum before they are willing to undertake any form of investment in radiocommunications networks;
- the pressures for change imposed by technical innovation;
- particularly in the fields of aeronautical, defence and space communications, Australia must take account of international factors;
- large portions of the spectrum have been set aside for purposes which are deemed to be socially necessary - defence, law enforcement and public safety. These forms of communications are guaranteed access to the spectrum and as a result the amount of the spectrum available to other users and uses is significantly limited;
- international agreements on specific frequency allocation, equipment and interference (although less so than most countries).

INTERNATIONAL MANAGEMENT OF THE RADIO SPECTRUM

The International Telecommunications Union (ITU) is responsible for the appropriate co-ordination of radio spectrum use internationally. Agreements between member nations on the use of the radio spectrum are reached which become binding on those member nations. Australia has an obligation to comply with ITU conventions as they have been ratified by the Australian Government giving them the status of an International Treaty.

The International Radio Consultancy Committee (CCIR) is the permanent organ of the ITU which issues recommendations on technical and operating issues relating specifically to radiocommunications. The CCIR recommend performance standards for radio systems to ensure effective and compatible interworking in the international telecommunications arena.

ITU World Administrative Radio Conferences (WARC) are held frequently at which agreement is reached on the use of the spectrum, the way in which it will be shared and the procedures adopted to ensure that it may continue to be regulated effectively and efficiently. The outcomes of WARCs become the broad plans for all member nations and impose obligations on the use of the spectrum at a national level. The ITU WARC 92 Conference, which will take place in Spain early this year, will be reviewing the frequency allocations for mobile services, shortwave

broadcasting, sound broadcasting by satellite and high definition television Australia. Industry is currently involved, in consultation with the Department, in preparing a national brief to address issues at the Conference.

Members of the ITU retain their sovereignty to do in their own countries whatever they choose to do with the spectrum, provided that they do not compromise the ability of other states to use the spectrum in accordance with ITU agreed designations. Because of Australia's geographical isolation, we have considerable scope for greater freedom of choice in how we manage the radio spectrum within Australia, without compromising our responsibility as a member of the ITU. Australia is therefore partly, but not totally, its own sovereign authority on the allocation and assignment of frequency.

Australia sources some of its radio technology from Europe and North America. These two sources are in different ITU regions and therefore can have different band allocations. One of the major Australian spectrum management problems is to develop national Spectrum and Band Plans which accommodate rationalisation of technical differences between North America and Europe.

An increasingly important issue in use of the radio frequency spectrum will be global consistency. In the very near future, we will see a proliferation of world wide communications systems, including perhaps the Iridium system of 77 small, polar-orbiting satellites. Systems like that will require co-ordination of frequency allocation across the world. Lack of co-ordination will inhibit our ability to derive many of the benefits which these developments can otherwise provide. If such systems are forced to work in different parts of the spectrum in different places, there will at the very least be additional technical obstacles to be overcome. Furthermore, efficiencies which can be achieved through mass production of equipment for a world market are likely not to be achieved if individual national markets are differentiated according to the frequency on which they operate.

OTHER SYSTEMS OF REGULATION/MANAGEMENT OF THE RADIO SPECTRUM

There has been a growing trend worldwide to seek alternatives to the traditional system of structured spectrum allocation plan and "first come first served" assignments. New Zealand has recently introduced a property market approach to spectrum management. This approach involves the creation of titles similar to those for ownership or leasehold of land with maximum reliance on market forces to determine the use. Occupancy rights are sold or leased by the owners of those rights which are of 20 years duration. Management rights and licences are freely transferable, subject to the provisions found in the New Zealand *Commerce Act 1986*. New Zealand has already auctioned the rights to several broadcasting and cellular bands. The New Zealand *Radiocommunications Act 1989* regulates the issuing and registration of management rights and licences. The Act does not dictate the purpose for which a person may utilise a frequency once a licence has been obtained, nor does it dictate who is entitled to acquire management rights or a licence.

The market-based approach has been criticised principally on the basis that it limits Government options for the future use of the spectrum. The Government may sacrifice aims such as creating new telecommunications services at the lowest possible prices. One major criticism is that this system will favour modern corporations and will not necessarily be in the public interest. Many claim that this type of system does not necessarily minimise scarcity as the Government loses flexibility to take advantage of long term opportunities or to meet long term and international obligations.

Those who favour the market-based approach to management of the radio spectrum draw an analogy between the radio frequency spectrum and land. It is said that both are scarce resources, and that the best way of determining their most efficient use is to let the market call the shots. Of course, land use in most countries, including Australia is not left absolutely to the market. Land use is heavily regulated - there are zoning controls and requirements for building and development approval. We protect various land uses in the social interest - coastal foreshore, public recreation areas, historic sites, roads and streets. Governments in Australia have compulsory powers of acquisition of land. Federal Governments acquire land for defence or airport buildings. State Governments require land to build schools or expressways - and increasingly to enable private consortiums to do so. Even Local Governments compulsorily acquire land.

If we move to a free market approach to allocation of the radio frequency spectrum, how should it be done? Should existing users be affected? Or should it only affect future users? Should there be compulsory powers of acquisition for uses regarded as socially important - whether in the public or the private sector? Will the market encourage the efficient use of spectrum, or will it be a means of hoarding spectrum, and stymieing potential users with innovative applications, but without deep pockets, or for holding to ransom those with deeper pockets? Is the market the best judge of optimum use of the spectrum?

- Technical efficiency: the Department is constrained in its ability to ensure that the most spectrum efficient and practices are in use;

- Public and merit goods: while the current system of spectrum management meets the needs of users who provide socially beneficial services to the community and those who use the spectrum for personal non-profit purposes, there is a need to ensure efficient use of the spectrum, particularly with respect to public sector users; and

- Allocation to highest value uses: the current system of spectrum management is not able satisfactorily to allocate spectrum to the highest value uses and this problem will become critical if demand continues to increase and congestion becomes more commonplace.

The Committee examined four possible approaches to addressing the shortcomings listed above:

1. An Administrative System

   An administrative system for setting priorities for allocation and assignment was not supported. The Committee found that such an approach would not meet the objective of being flexible and responsive to changes in demand, particularly if levels of congestion were to increase. Furthermore, the potential costs associated with a system of comparative assessment for assignment could impose significant costs on spectrum management which would have to be borne by users on a cost recovery basis.

2. Fine Tuning the Current Administrative System

   The Committee found that suggested reforms to the current spectrum management system would contribute to improving the responsiveness of spectrum management to technological change and increasing demand, however, there would continue to be some essential weaknesses. In particular, the Committee stressed the following:

   (i) replanning and reassignment of frequency allocations would still be limited because of the problems associated with compensating users for the costs associated with replanning;

   (ii) there is no incentive for users to utilise spectrum in the most efficient manner possible, except the fear of losing an assignment;

   (iii) resumption is likely to be a long and drawn out process which may in fact make spectrum management even less responsive; and

   (iv) the suggested reforms do not address the need to ensure that spectrum is allocated to the highest value uses in situations where demand exceeds supply.

3. A Market Based System

   The Committee stated that tradeability of spectrum resources offers significant advantages in relation to the objectives of dynamic efficiency and technical efficiency over the current administrative approach. In particular, the establishment of a market would:

   (i) enable users to acquire spectrum or relocate to new spectrum in response to their changing needs;

   (ii) encourage users to optimise their use of spectrum in order to maximise the returns on their investment;

   (iii) provide an effective solution to the problem of compensation for users who move to new spectrum or to other means of service delivery;

   (iv) provide non-commercial users with some incentive to seek to use their spectrum more efficiently as they would be able to sell or lease out excess requirements and use the funds to finance improvements in equipment;

   (v) provide a means of recouping any economic rents from users in such a way that it does not distort investment decisions; and

   (vi) facilitate allocation to the highest value uses for commercial applications.

The Committee determined, however, that a comprehensive market based system covering all spectrum users and uses should not be introduced at the current time as there are some significant uncertainties, particularly with regard to ensuring continued access for public sector and non-profit organisations and the potential difficulties with interference.

4. A Mixed Market/Administrative System

The Committee recommended that reforms to the current system should be undertaken in parallel with the development of a market system. The Committee's approach to a mixed market/administrative system would generally restrict the tradeability of spectrum access to commercial applications in order to protect non-commercial users from premature exposure to a market based system until means have been devised to resolve current uncertainties. The Committee recommended that the Department develop an implementation strategy for a mixed market/administrative system and that this proposal be developed in parallel with recommendations for change to the current administrative system. The Committee also recommended that non-commercial users should have the choice of remaining under the current administrative system or having their licences converted to a tradeable resource. Other recommendations included that a system of regular auditing of spectrum used by public sector users be introduced and that tradeable spectrum access should not be perpetual, but should provide tenure for a fixed term.

The Government is yet to respond to the Parliamentary Committee's recommendations but the expectation is that the Government is likely to be strongly guided by the Committee's detailed report and proposals. A Government response is expected in late 1991 or early 1992.

THE BROADCASTING SERVICES BILL

Recent months have also seen proposed radical changes in the management of the allocation of radio frequency spectrum affecting Australian broadcasters. In November 1991 the Commonwealth Government released the *Broadcasting Services Bill* for public comment. That exposure Bill proposes sweeping reforms to all aspects of Australian broadcasting regulation, including the abolition of the Australian Broadcasting Tribunal and its replacement with the Australian Broadcasting Authority ("ABA") and the conferral on that body of a wider range of functions than is currently vested in the ABT, including planning functions relating to frequency allotment for particular broadcasting services. In discharging its planning and licensing functions, the ABA will be under a statutory obligation to ensure maximum use of the radio spectrum is made, a requirement which is likely to lead to greater competition in the broadcasting industry.

A streamlined regulatory approach has been proposed which includes:

- a simplification of the licensing criteria, with the only key criteria being the suitability of the licensee;
- a simple licence allocation process in most cases, although community licences will still involve merit-based gains;
- virtually automatic licence renewals; and
- class licences for all narrowcasting services and non-satellite pay services, in accordance with the telecommunications model.

Under the proposed Bill, the licence allocation process will be preceded by a planning process, involving the following four stages:

1. Assignment of radio frequency spectrum by the Minister to the broadcasting services band (with a ministerial power to reserve part of that band for national and community broadcasters);
2. The ABA is to set priorities for the development of frequency allotment and licence area plans;
3. Frequency allotment plans specifying the frequencies available in various parts of Australia for broadcasting services are to be developed by the ABA; and
4. The ABA will have discretion to determine licence area plans for the purpose of allocating all available spectrum capacity.

Commercial radio and television licences are to be allocated according to a price-based competitive system. The particular system to be adopted is within the discretion of the ABA, subject to any directions issued by the Minister. Such a system already operates under the National Metropolitan Radio Plan, which permits conversion of two AM radio licences to FM under a tender system for each capital city.

In transferring responsibility from the Minister to the ABA for planning designated parts of radio frequency spectrum, the Bill seeks to introduce greater transparency and accountability for planning decisions by obliging the ABA to conduct public consultation processes. While moves towards increased public participation in planning processes and wider public accountability are welcome, fundamental issues are raised regarding the appropriateness of vesting in a single administrative body such a diverse range of legislative, administrative and quasi-judicial functions. The ABA's proposed planning and licensing functions are especially controversial in posing a challenge to established concepts of the separation of powers enshrined in the Australian Constitution. These and other aspects of the Bill are likely to be the subject of extensive public comment during the next few months. Public comment on the Bill is scheduled to conclude in February 1992 with the current expectation being that the Bill will be considered by the Federal Cabinet some time during March, prior to its introduction in Parliament and expected passage in mid-1992. If that timetable is adhered to, and there must be some doubts that it will given the recent change in Ministerial personnel affecting the broadcasting portfolio, Australia could witness the implementation by mid-year of the most radical changes to broadcasting and radiocommunications regulation seen in that country for decades. Such major reforms would sit aside alongside the equally bold reforms enacted by the Australian Parliament earlier this year in relation to telecommunications.

NEW OPPORTUNITIES IN AUSTRALIAN TELECOMMUNICATIONS

SPEECH FOR THE PACIFIC TELECOMMUNICATIONS COUNCIL PTC'92

13 JANUARY 1992

ANDREA GROSVENOR
Assistant Director
Regulatory Policy Section
Telecommunications Policy Division

11.0

NEW OPPORTUNITIES IN AUSTRALIAN TELECOMMUNICATIONS

At PTC'91, Vanessa Fanning of the Australian Department of Transport and Communications introduced the Australian model for telecommunications reform. At that stage, the policy decisions had been made, and the implementation was about to begin. Today, all of the necessary legislation and most of the procedures to give effect to the policy decisions are in place, and Australia's second carrier has been named.

The change process has not been an easy one. The level of consultation with all affected parties has been unprecedented in Australian legislative reform, with exposure drafts of all of the major pieces of legislation and many of the subordinate instruments being widely circulated for comment before finalisation. This has helped to some extent to "sell" the changes to the industry and the community, and it also provided much useful input to the drafting process itself, with many of the suggestions received during the consultation phases being incorporated into the final products.

The changes and their implementation has also faced considerable opposition. The most contentious issues were the terms for interconnection between the existing carrier and the new carrier; the rapid establishment of real competition across the range of telecommunications services; the protection of consumers; and the merger of Australia's domestic and international carriers.

The Government policy decisions that were implemented in 1991 build on and extend the reforms that commenced in the mid-1980s. Major policy objectives include: promotion of competition and fair and efficient market conduct; efficient, accountable and responsive telecommunications carriers; Australia-wide access to the standard telephone service; development of Australia's telecommunications capabilities, industries and skills; and a framework which is sufficiently flexible to accommodate developing technology.

The 1990-91 reform package will further the establishment of an open, pro-competitive telecommunications regulatory environment, one which we believe to be among the most progressive in the world.

The main elements of the 1990-91 reforms are:

. the introduction of a transitional duopoly in network services provision through the licensing of a second network operator, based on the sale of AUSSAT, the domestic satellite carrier;

- the implementation of pro-competitive safeguards, including equal access and interconnection between the carriers;

- the issuing of three public mobile telephone service licences, one each to the existing and the second carriers, with the third to be issued by the end of 1992;

- the merger of the Government's domestic and international public network operators, Telecom and OTC, to form the Australian and Overseas Telecommunications Corporation (AOTC);

- the introduction of unrestricted network competition from 1997;

- open competition in the provision of public access cordless telecommunications services (or CT2);

- full resale of domestic and international capacity; and

- a mandate for the telecommunications regulatory authority, AUSTEL, to promote competition.

The second general and mobile telecommunications licences will be awarded to Optus Communications, a consortium comprising BellSouth, Cable and Wireless, and majority Australian-ownership through Mayne Nickless, AMP, National Mutual and the AIDC Telecommunications Fund. The merger of Telecom and OTC will be effected early this year, following the establishment of competitive interconnection arrangements for Optus to have equal access to Telecom's network infrastructure. This is a major step in the latest round of reforms.

I don't propose to talk in detail about the changes or the ways in which the implementation difficulties have been overcome, but will focus instead on where we see the major opportunities arising out of the reforms. Suffice it to say that we are confident that the changes will be effective, and that Australia will have a more efficient, dynamic and responsive telecommunications sector as a result.

Telecom Australia has already achieved one of the world's highest penetration rates for basic services, with 95 per cent of households having access to the network, and the Australian public's adoption of new telecommunications technologies, such as cellular mobile phones, has been among the fastest in the world. Mobile services in operation increased by 58 per cent in the year to June 1991, so that there are now nearly 300,000 mobile subscribers in Australia's population of just 17 million.

The new marketplace offers even more opportunities for all industry players. It is important to note that when we talk about the participants in the industry, we include not only the licensed general and mobile carriers, but also service providers (including resellers, value added service providers and private network operators), equipment suppliers, unions and employees within the industry, and, of course, consumers, both business and domestic.

Now let me describe some of the benefits that we envisage over the next few years.

CARRIERS

Until 1997 Australia will have two network carriers, AOTC and Optus.

AOTC

The [redacted] Government-owned AOTC will be formed by merging the pre-existing domestic and international operators. It will operate from early 1992 as a commercial enterprise across the full range of telecommunications services. It is established as a "commercial" entity, that is, as a company under corporations law, with a Board comprised of a wide range of business, industrial and legal skills, and a commercial capital structure.

Telecom is one of Australia's largest companies with total assets of $22.5 billion as at 30 June 1991. It made a net profit after tax of $869.5 million for the year ending 30 June 1991, and employs around 77,000 people. OTC Limited had total assets of $1.5 billion at 31 March 1991, and made a net profit after tax of $276.6 million for the year ending 31 March 1991. OTC employs 2,300 people. The merged AOTC will be the fifteenth largest telecommunications company in the world.

The Government's intention in merging Telecom and OTC amounts to much more than merely rationalising the assets, resources and businesses of the two enterprises. The aim is to create an Australian telecommunications company that is genuinely internationally competitive. Its established position in the domestic market provides a strong base from which to expand internationally. The introduction of competition will also stimulate it to become more efficient and commercially-oriented.

The present Australian Government has decided to retain AOTC in government ownership, although it is the publicly stated intention of Australia's other major political parties to privatise AOTC in the event that they win Government in the next election, due in 1993.

Optus

Optus will receive its carrier licences on closure of the sale of AUSSAT, which we anticipate being on 31 January. Optus expects to commence operations with the resale of mobile capacity from Telecom's AMPS network within about four months, and to start offering other services in the fourth quarter of this year.

A prime reason for international interest in the second carrier licence is the strategic position of Australia's current network and regulatory regime. Australia also provides Optus with an excellent base for continued technological development, access to the emerging world markets (particularly Asia), and a regulatory environment at the forefront of international trends towards deregulation.

The opportunity to build a second network operator almost from scratch with full interworking with the established network and no regulatory restrictions on technology, services or market coverage has rarely arisen, but the future development of telecommunications elsewhere is likely to provide other opportunities to do so. Those who have learned in Australia will be well placed to transplant their knowledge.

In addition to the $A800 million that it is paying to buy AUSSAT, Optus has indicated that it will invest $A2 billion over the next six years in establishing operations in Australia. The investment scheme includes plans to draw in local industry and achieve a local content level of 70 per cent over the next five years. The plan also incorporates $A15 million for a training institution, another $A100 million for training costs and an additional $A50 million on research and development. Optus expects to create over 5000 direct jobs in Australia.

Competitive Safeguards

The Australian regulatory model for managing the transition from a monopoly to a competitive telecommunications market offers Optus the opportunity to become a significant operator in the Australian market in quite a short period of time. There is no question that AOTC has strong advantages in areas such as customer base, infrastructure and access to information. These advantages had the potential to be used to inhibit the development of widespread competition and restrict competitive entry to the market by the second carrier. Overseas experience showed us that without equal access safeguards, the introduction of competition is likely to be at best slow and limited.

The benefits of a competitive telecommunications market best flow to the community when there is real pressure on

the carriers to reduce prices, increase service offerings and improve their responsiveness to customers' needs. Optus must be given the opportunity to establish a significant presence in the Australian market to provide genuine competition to AOTC.

The Australian Government decided that the best way to achieve a deregulated, competitive structure for the long-term was to implement specific pro-competitive regulation for the short-term. The package of competitive safeguards introduced into the Australian legislation includes measures relating to the interconnection of the second carrier to Telecom's infrastructure, customer access, numbering, directories and the regulation of cross-subsidy and accounting separation.

Many of the special conditions applicable to Optus in the first instance will cease to apply when AOTC's market dominance is significantly reduced. For example, the initial regulated charge for Optus to interconnect to the AOTC network is set to cover the long-run marginal cost of providing the service to Optus and will apply in areas where AOTC maintains market dominance or bottle-neck power. Subsequent interconnection charges are to be commercially negotiated between the carriers.

Global Focus

While the primary focus of most large carriers has traditionally been on their home markets, leading carriers are now seeking to build global businesses by bidding for contracts to design, build and operate networks in international markets. International activity is necessary today in order to maximise growth and shareholder returns, and the demand by consumers for access to the best new technologies ensures that markets are available. Keeping up with the technologically-affluent Joneses is an important aim of any country wanting to be a player in the international economy today. It's not just access to the technology that is important, however. Governments are increasingly aware of the benefits of encouraging competition in their domestic markets in order to strengthen their global position.

Leading carriers are motivated by a need to secure sufficient scale to buy equipment and services efficiently, fund R&D programs and serve customers world-wide. For AOTC and Optus to be at the industry forefront, they too will need to pursue international markets, especially in the rapidly growing Asia/Pacific region.

A recent study by Australia's Allen Consulting Group, commissioned by the Australian Department of Industry, Technology and Commerce, estimated that by the year 2000 the total revenues of Australian-based carriers could

approach $A50 billion, nearly half of it generated off-shore.

AOTC will succeed in international markets on the basis of Telecom and OTC's reputations for being smart developers and operators of the latest technologies and good managers of large scale networks. For example, at last year's Oracle Users' Asia-Pacific Conference, Australia's OTC's Oracle database for its intelligent network management system was judged the best in the Asia-Pacific. Aside from the advanced networks they operate in and from Australia, Telecom and OTC have significant involvement in operating networks in other countries, including Saudi Arabia, Vietnam and Pakistan.

Optus has indicated through its development and investment plans that it will be competitive both domestically and internationally. This is also evident in the Optus consortium members' records of competitiveness both in telecommunications markets and in their respective industries.

SERVICE PROVIDERS

Australia should be well placed to play a significant role in providing global telecommunications services, particularly to the Asia/Pacific region. The Australian carriers are innovative and have many leading edge capabilities to offer in the areas of network and mobile services. Huge growth is also anticipated in the export of value added and professional services, for example, software, electronic data interchange and facilities management. Australian service providers can access international markets through network operation, strategic alliances, direct investment or hubbing.

Australia has a growing and competitive market for value added and other telecommunications services. Since the opening of provision of value added services to full competition in 1989 a broad range of innovative services has been established.

This sector is expected to grow further with the removal of restrictions on third party resale of telecommunications capacity. Private network operators may now make the most efficient use of their networks by disposing of or sharing spare capacity, and their customers can take advantage of access to a wider range of private network services.

The decision to allow resale is a very significant liberalisation, and it is fair to say that Australia's approach to resale is possibly the most liberal in the world. The new arrangements allow Australian service providers to resell capacity for both voice and data services and to engage in both value added and "simple"

resale. This applies to the resale of international as well as domestic services.

Australia anticipates that its acceptance of international resale will also contribute to hastening the now much-needed reform of the traditional international accounting and settlement rate regime that is serving to distort seriously the economics of international telecommunications services.

The Australian Government is aware that there are some risks in unilaterally pursuing an open resale regime, particularly if this could lead to foreign telecommunications operators, operating under less liberal regimes, being able to take unfair advantage of Australian carriers or service providers. It has therefore directed the regulatory authority, AUSTEL, to provide safeguards in certain cases, set out in an AUSTEL class licence. Class licences are designed to allow the maximum flexibility to service providers, while at the same time ensuring that minimum technical standards are maintained, and that the practical value of the carriers' reserved rights are not unduly eroded. It is a passive licensing system in that applicants don't need to make a licence application and wait for an approval, they simply need to comply with certain simple rules of conduct.

WIRELESS AND MOBILE SERVICES

Cellular mobile telephone services are becoming highly important in their own right and also as a complement to basic services in the Asia/Pacific region. While mobile has until recently been viewed as a specialised service, more extensive wireless communications services hold out the potential to provide a systemic alternative to the wired PSTN through the development of personal communications networks, wireless PABXs and other developing technologies.

In Australia we are expecting to see the new telecommunications operators make use of wireless technologies as one way of rapidly differentiating themselves and their services from AOTC. At the same time, AOTC will be working hard to develop and implement the much sought after universal personal telecommunications system. Regulatory systems which can impede the introduction of new technology, such as the spectrum allocation system and type approvals procedures, are being overhauled in tandem with the wider telecommunications reforms.

An analogue cellular mobile telecommunications service was established in Australia by Telecom in February 1987. In geographic terms, it is the largest single cellular mobile system in the world, covering most of the inhabited parts of Australia. Digital services, based on the European GSM

standard, will be introduced from 1993. The existing analogue service will be phased out progressively between 1996 and the year 2000. There will be a period of overlap between analogue and digital technologies to provide customers with adequate time for conversion to the new technology.

AOTC and Optus have been granted mobile licences. A third public mobile licence is to be issued by December 1992 for commencement of services in July 1993. The issue of any additional mobile licences will be considered in 1995.

Until it has its own digital cellular infrastructure in place, Optus will have access to Telecom's network and will resell airtime. Both AOTC and Optus will be installing GSM networks over the next few years.

The Australian mobile market will provide one of the first large-scale GSM developments outside Europe and thus will ensure that international attention is focussed on us as we establish and "road test" our system. In view of the track record of Australian industry in adapting and inventing ingenious solutions for our geographic conditions, there are bound to be many interesting developments of the mobile networks. Telecom particularly has already found that it can export expertise to countries with similar conditions, turning "problems" into "opportunities". Its international arm, Telecom Australia (International), has recently taken a controlling stake in the private sector company, Uni-Net, to build and operate a two-way radio network, a paging network and a radio telephony system in rural Poland, using Australian developed technology.

Public Access Cordless Telecommunications Services (PACTS)

PACTS, using the current CT2 standard approved by AUSTEL, are expected to fill a niche between public mobile telecommunications services and public pay-phones. These services can be provided by current and emerging technologies and complement the expanding fixed telephone network.

The supply of PACTS is fully open to competition. PACTS operators are subject to a class licence administered by AUSTEL. The class licence sets out the terms and conditions which must be complied with by the PACTS suppliers. An exclusive spectrum allocation of 861-865 MHz has been allowed for PACTS. The usage of this band will be reviewed by January 1994.

To date there are no PACTS services operating in Australia, however OTC International, in partnership with Chevallier Telecommunications, has been granted one of four CT2 licences in Hong Kong. Telecom has not yet announced its plans for any domestic PACTS operations.

EQUIPMENT SUPPLIERS

From an equipment supplier's point of view, AOTC's implementation of advanced technologies and R&D capabilities are important factors in the supplier's commitment to maintain and expand their Australian activities and develop their export potential. To remain world class suppliers, many multinationals recognise that they need to locate research and production facilities close to leading edge customers such as AOTC, and need to maintain their strategic relationships. Some have noted that being a supplier to Telecom and OTC is an advantage when they are bidding for contracts with carriers in other countries.

Telecom and OTC are currently consolidating long term network system/supplier relationships. It is likely that AOTC's choice of suppliers will remain the main determinant of supplier market share, entry and exit. Telecom now deals primarily with Ericsson, Alcatel Australia and NorTel for switching equipment, and Ericsson, Alcatel, NEC, Fujitsu and Siemens for transmission systems.

Optus has secured deals with NorTel and Nokia for switching systems and radio equipment respectively. Nokia plans to establish an Australian centre for research into indoor cordless and micro-cellular telecommunications systems.

Industry Development Policy

The Australian Government is keen to promote the commercially sustainable development of Australian industry in order to achieve forecast growth in exports of $2 billion in this industry. It is committed to a framework for the development of the industry, including:

- maintenance of a quality network;
- promoting the liberalisation of international telecommunications goods and services markets in multilateral and bilateral forums;
- promotion and maintenance of long-term strategic relationships between the carriers and global equipment suppliers. This could involve world or regional mandates in switching, transmission and network management;
- support for the development of new innovations in software and R&D skills in telecommunications;
- endorsement of local industry through Government purchases of telecommunications services and equipment; and

- consultation between the Federal and State Governments in the development of a national approach to industry.

Telecom has had a long term commitment to the Australian telecommunications equipment industry. This has been commercially driven, and Telecom has seen close links with local industry as a sensible way to do business. AOTC will continue to support the industry development fostered by Telecom and OTC, and will submit an industry development plan to the Government later this year.

Optus will be working to ensure that tangible benefits flow from the corporation's preferred supplier agreements, which will provide for technology transfer between international vendors and local suppliers, research and development and substantial local manufacturing.

There are plans to establish a Bell Northern Research laboratory at Australia's Wollongong University with responsibility for R&D into advanced personal communications and wireless/fixed network integration as well as advanced intelligent network systems.

Optus has forecast that its commercial supply arrangements and partnerships will lead to 70 per cent of its total capital program for network development being sourced in Australia.

CONSUMERS

The Australian public has a healthy scepticism of Government-directed change to institutions which the community has come to know and rely upon. While complaining about Telecom has become a national pastime, many interest groups have expressed concern about the changes being made. They needed to be convinced that positive outcomes for the community as a whole would result, and that the level of service available to the ordinary domestic consumer would not fall, nor prices rise. The rural population, which has traditionally enjoyed considerable cross-subsidisation of the cost of their telephone access, was concerned that a fully commercial telecommunications enterprise would not treat them so favourably.

At the time the new telecommunications policy structure was being developed in 1990, the then Australian Prime Minister gave a public undertaking that no rural or household user would be disadvantaged. Partly to achieve this, price caps have been applied to AOTC's domestic service rental, and local, trunk and international calls. Further real price reductions will be achieved through productivity improvements, benefiting all consumers.

At the same time, the Government has maintained its emphasis on continuing to provide all Australians with access to a standard telephone service. A legislated obligation to continue to provide universal service has been placed on AOTC. Any genuine commercial losses associated with this system will be funded by both carriers in proportion to their traffic.

In view of the virtual universal access that Australians now have to a telephone, the policy focus has shifted away from this goal and onto equity issues, that is, ensuring that the basic service is delivered as equitably and efficiently as possible. Ground-breaking work in Australia has resulted in a model for costing, funding, targeting and delivering community service obligations that we are confident will meet this aim. Selling this concept to some sectors of the community, including some existing carrier interests, has not been easy either.

Business users are already experiencing the benefits of competitive provision of customer equipment and some services through lower prices and greater choice. As telecommunications becomes a larger and larger proportion of a business's expenditure, the need to reduce this input cost of doing business becomes more important. And as the world becomes the local marketplace, it is vital that businesses have access to high quality, instantaneous, global telecommunications facilities.

The liberalisation that has occurred in Australian telecommunications since 1989 has made the business community more aware and more demanding of the best in telecommunications goods and services. We believe that the framework we are establishing will encourage carriers and service providers to meet these needs.

CONCLUSION

The telecommunications industry of the future is a global one, and it is user-driven. Australian telecommunications reforms since 1988 have consistently recognised the importance of positioning our industry - carriers, service providers and manufacturers - in a competitive position in the world market.

With an eye to strong and genuine competition in the longer term, the Government has decided to move from a monopoly structure to full and open competition in 1997 by way of a regulated transitional duopoly. This transitional stage will enable the new Government carrier AOTC to consolidate, and will ensure the emergence of a second carrier which is a real competitive force. The Government is confident that consumer benefits will flow from increased competition. Nevertheless, a range of measures, including regulation of the dominant carrier's prices and AUSTEL monitoring, will

safeguard the interests of all users. This is a win-win game.

The new environment is also outward-looking. As a result of increased national competitiveness, international investment and the dismantling of regulatory barriers, the Australian telecommunications industry will become more export-oriented and better positioned to take advantage of the opportunities of the 1990s and beyond. The new environment encourages carriers, service providers and equipment suppliers to go out and win business overseas. Complementing these changes in the "local environment", the Government actively supports further liberalisation of the international telecommunications market.

Within this context, the Australian approach to telecommunications reform is a different model from any undertaken elsewhere in the world to date. We know that many other countries, looking to move from a regulated to a competitive telecommunications market, are watching the progress of our regulatory framework with great interest. We are confident that it will deliver the goods.

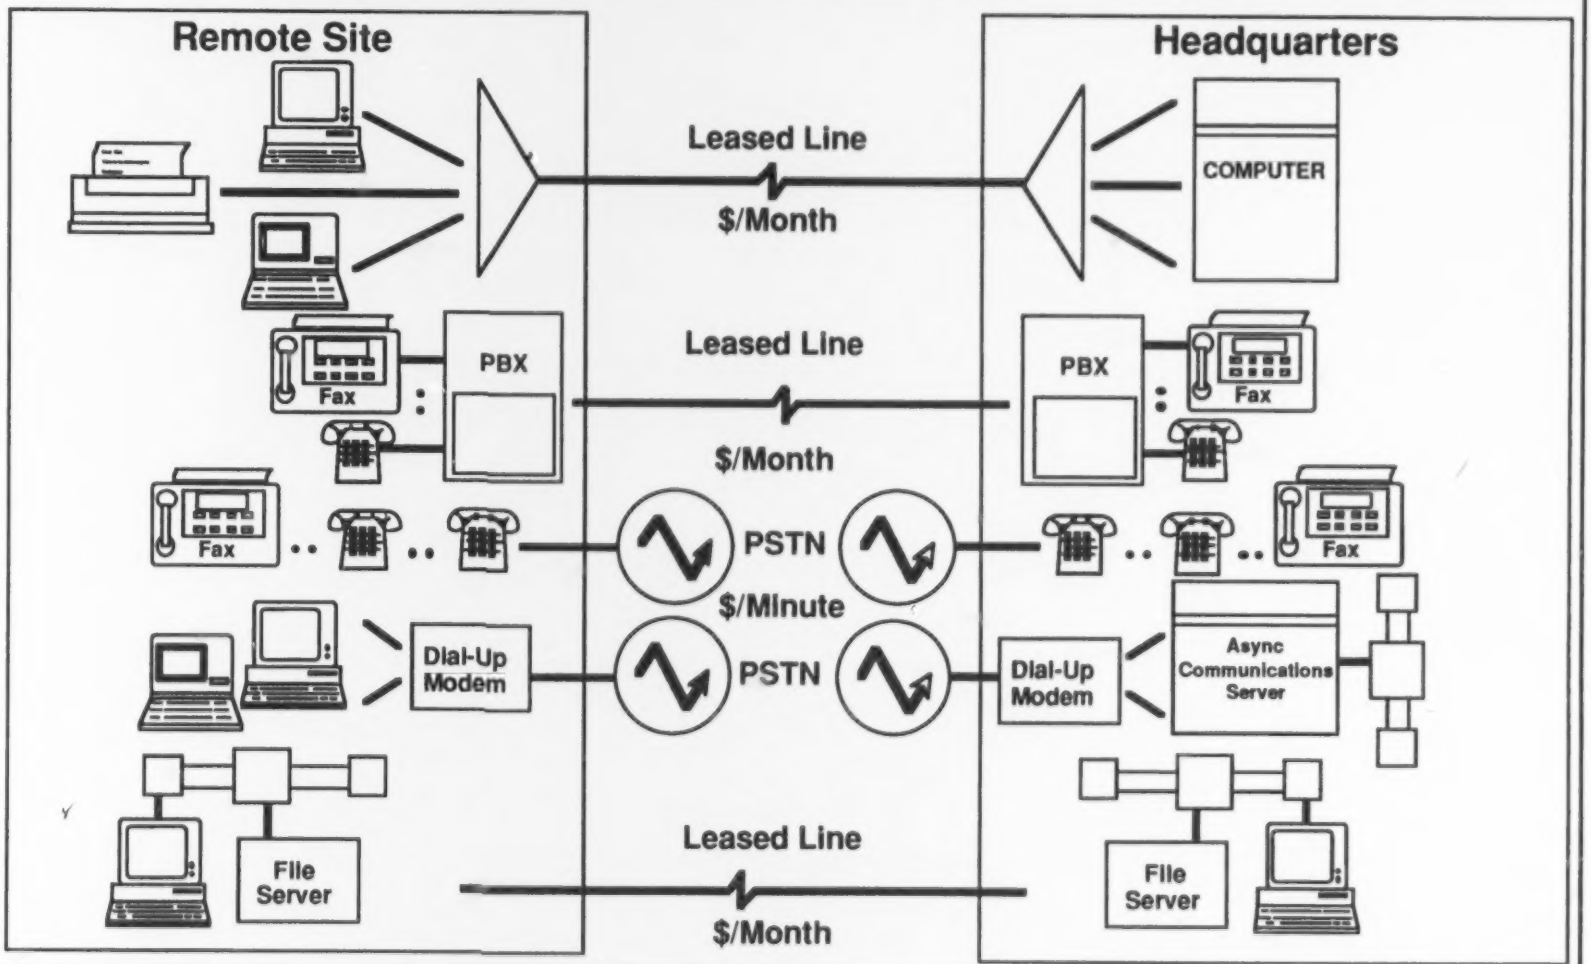
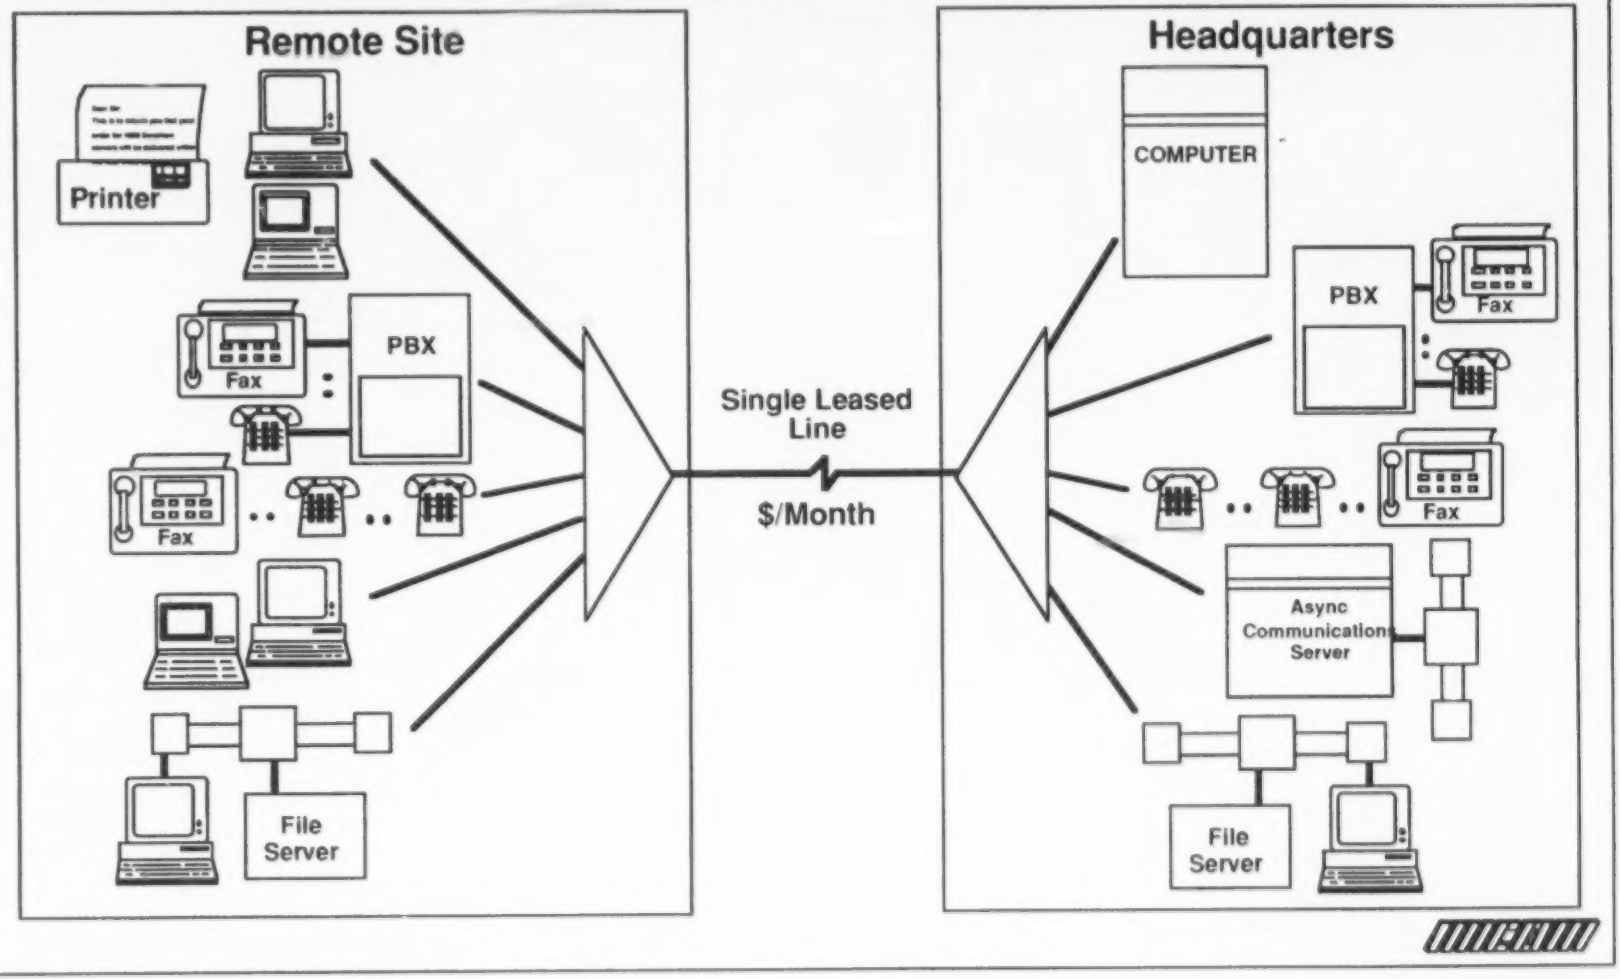
UNINTEGRATED REMOTE-SITE COMMUNICATIONS

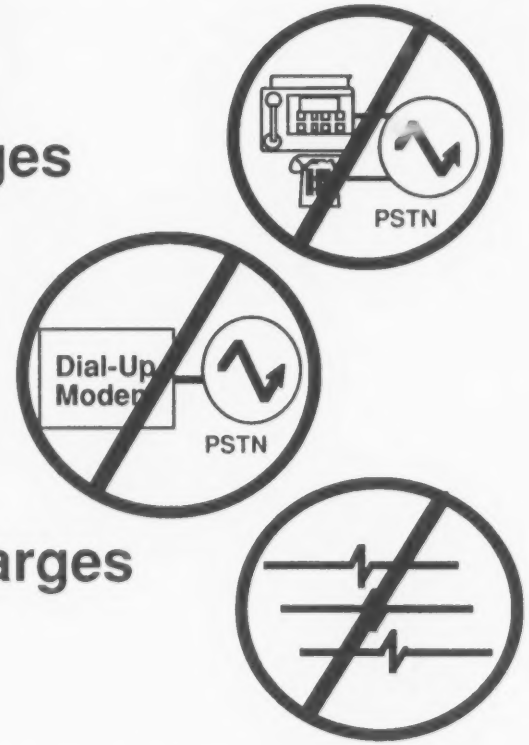


INTEGRATED REMOTE-SITE COMMUNICATIONS



INTEGRATION ADVANTAGES

- **Save Money by Eliminating:**
  - **Voice and Fax Toll Charges**
  - **Dial-up Modem Charges**
  - **Multiple Leased Line Charges for Voice and Data**



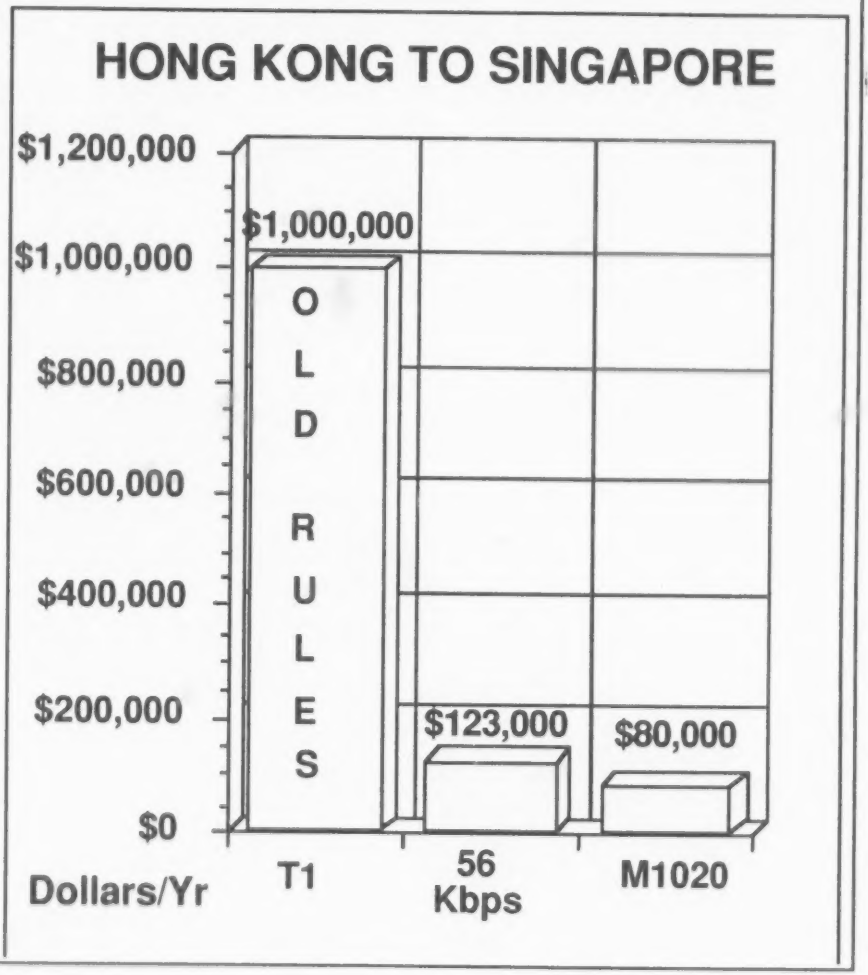
- **Other Benefits of Integrated Networking**

OLD RULES FOR INTEGRATED COMMUNICATIONS

- Use a Leased T1/E1 Line at 1.5-2 Million Bits/Second
- Use Time Division Multiplexing and Pulse Code Modulation
- Use T1/E1 Multiplexers

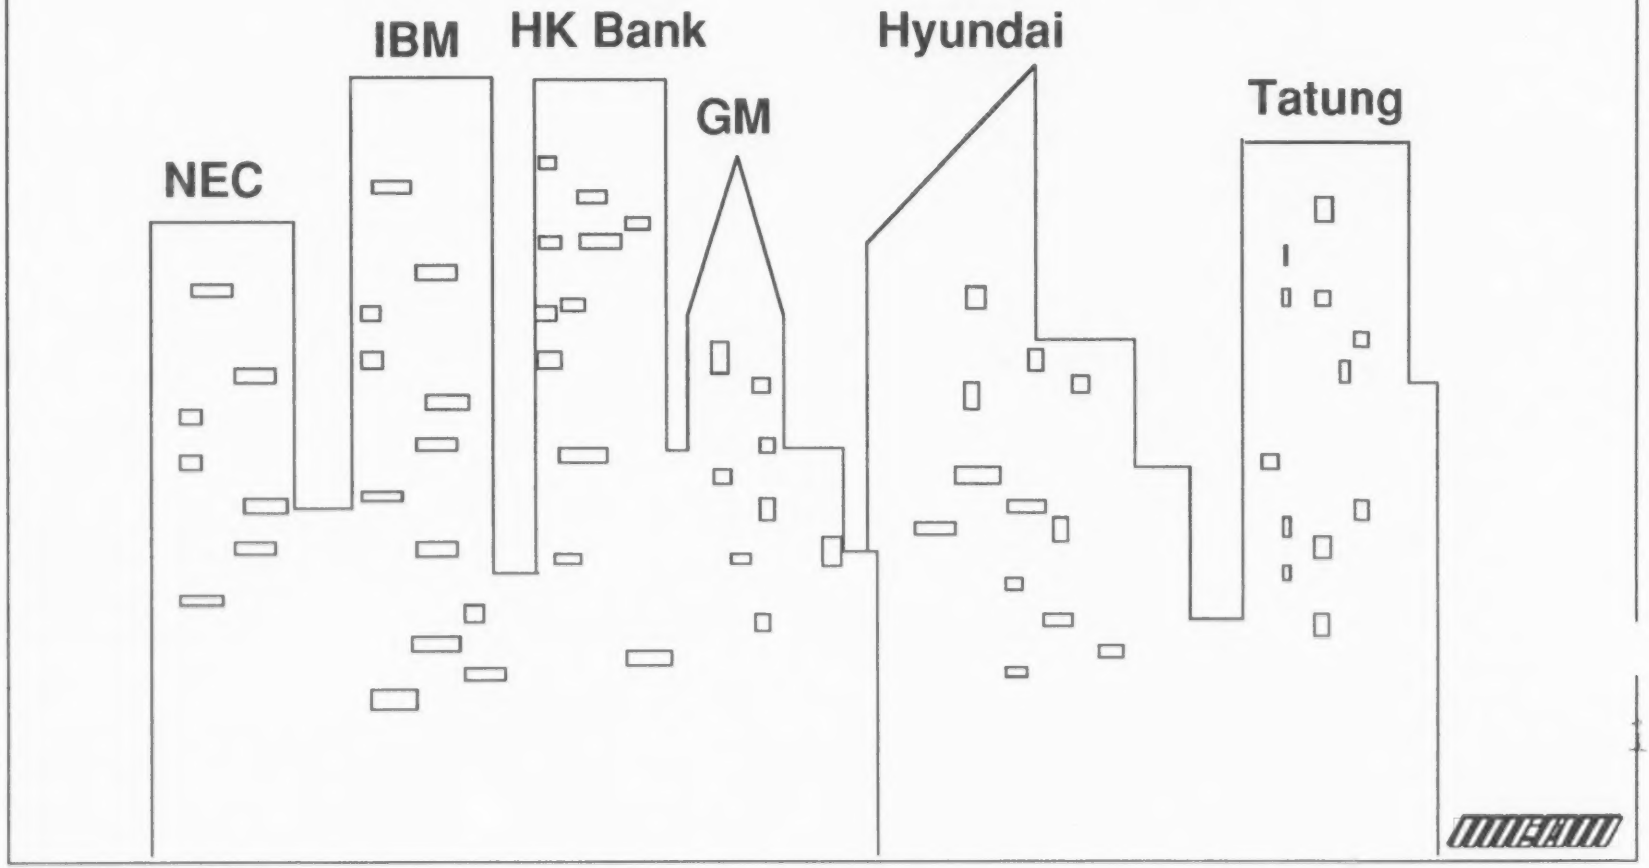
WHY DOESN'T EVERYONE INTEGRATE?

- Old Rules are Too Expensive
  - Large volume of toll traffic
    - 40 to 60 hours/day
  - 8-16 leased lines



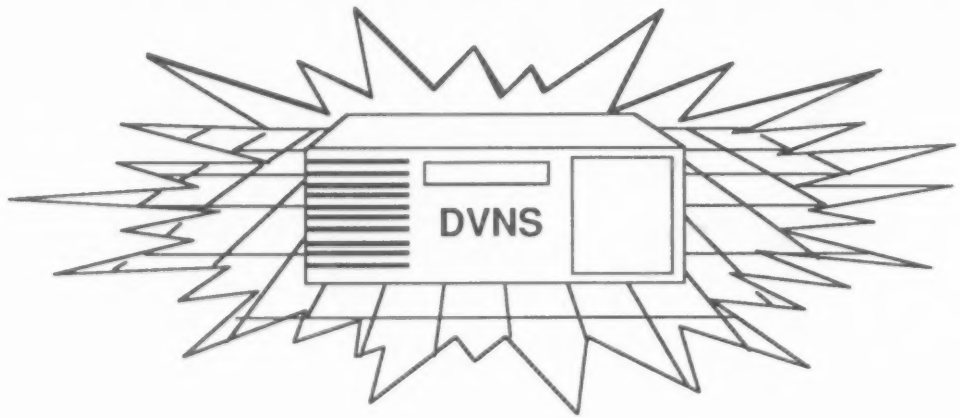
WHY DOESN'T EVERYONE INTEGRATE?

- Old Rules Only Work for Larger Companies



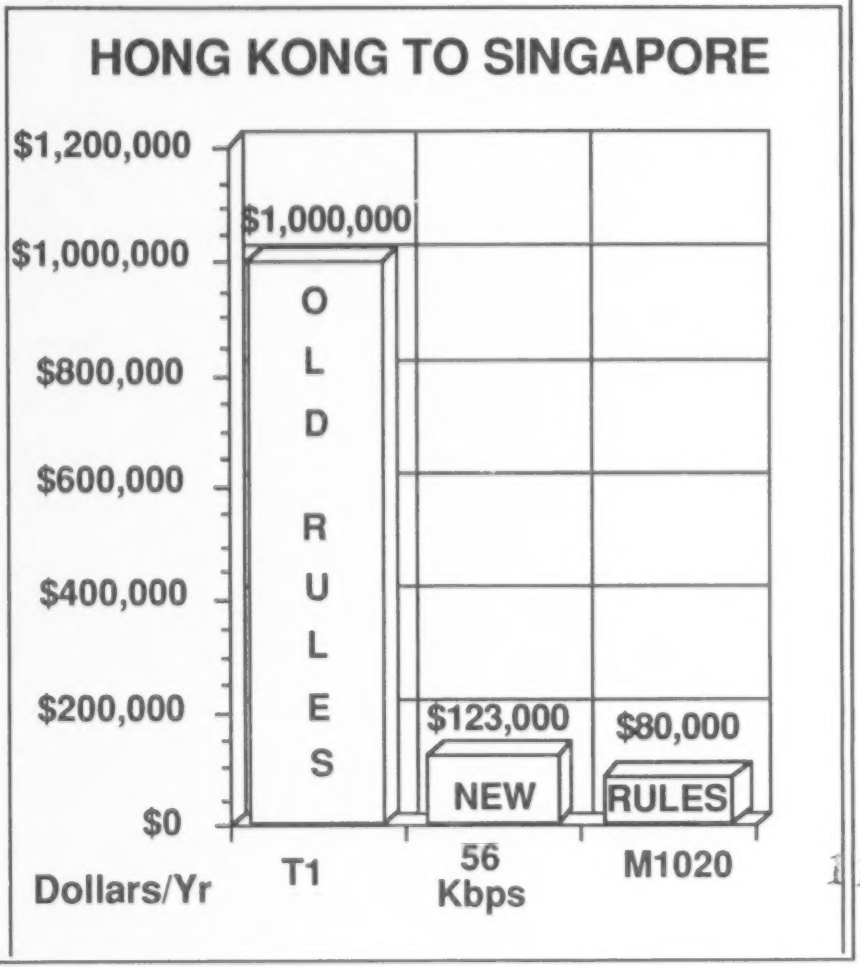
NEW RULES FOR INTEGRATED COMMUNICATIONS

- Use Low-Speed, Low-Cost Leased Lines
- Use Fast Packet Multiplexing and Advanced Compression Techniques
- Use Data/Voice Network Servers—DVNS



WHY EVERYONE CAN NOW INTEGRATE

- **New Rules are Affordable**
  - **Low volume of toll traffic**
    - **1/2 to 1 hour/day**
  - **1-2 leased lines**



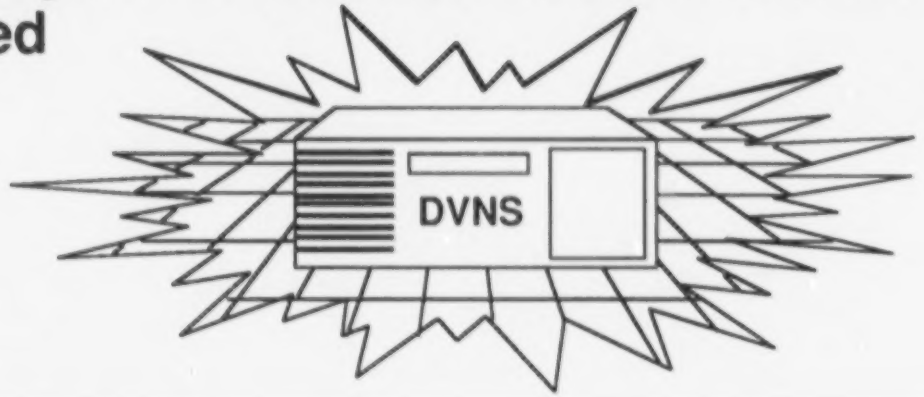
THE BOTTOM LINE

- New Technology Has Changed the Rules
- All Companies - Small, Medium, and Large - Can Now Afford to Integrate
- The Days of the Single Purpose WAN Are Over
- The Days of the Data-Only Mux Are Over

A NEW ERA OF REMOTE COMMUNICATIONS

- The Days of Multipurpose WANs Are Here

- The Days of Data/Voice Network Servers Have Arrived



DVNS USER PROFILE

- Has Leased Line for Data/LAN, and Voice/Fax Toll Calls
- Has Leased Voice/Fax Tie Line and Data/LAN Toll Calls

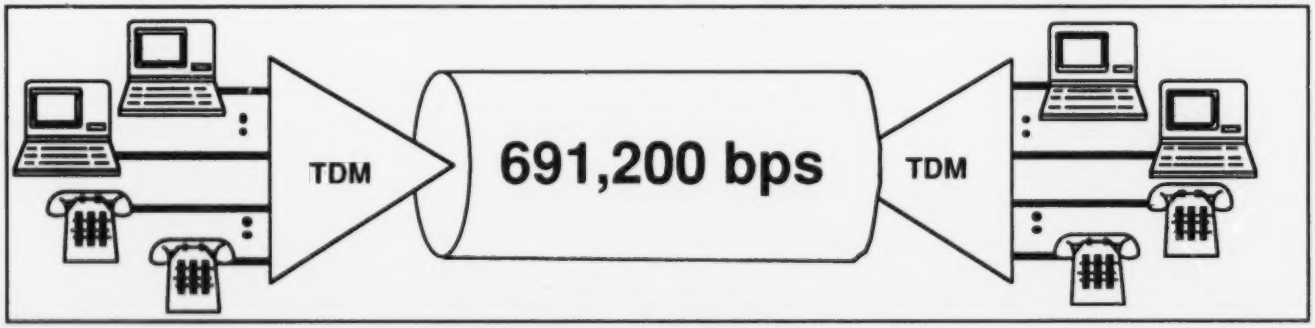
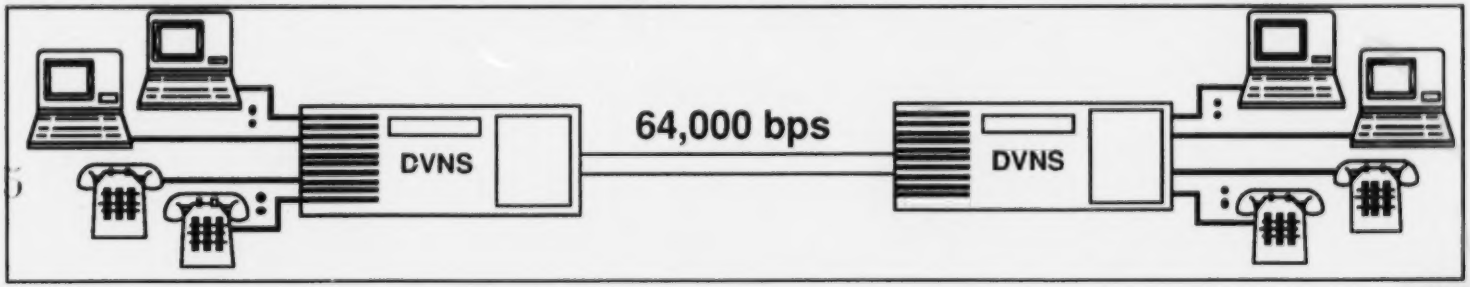
4 month payback

TECHNOLOGY IMPACT ON 56/64 Kbps LINES

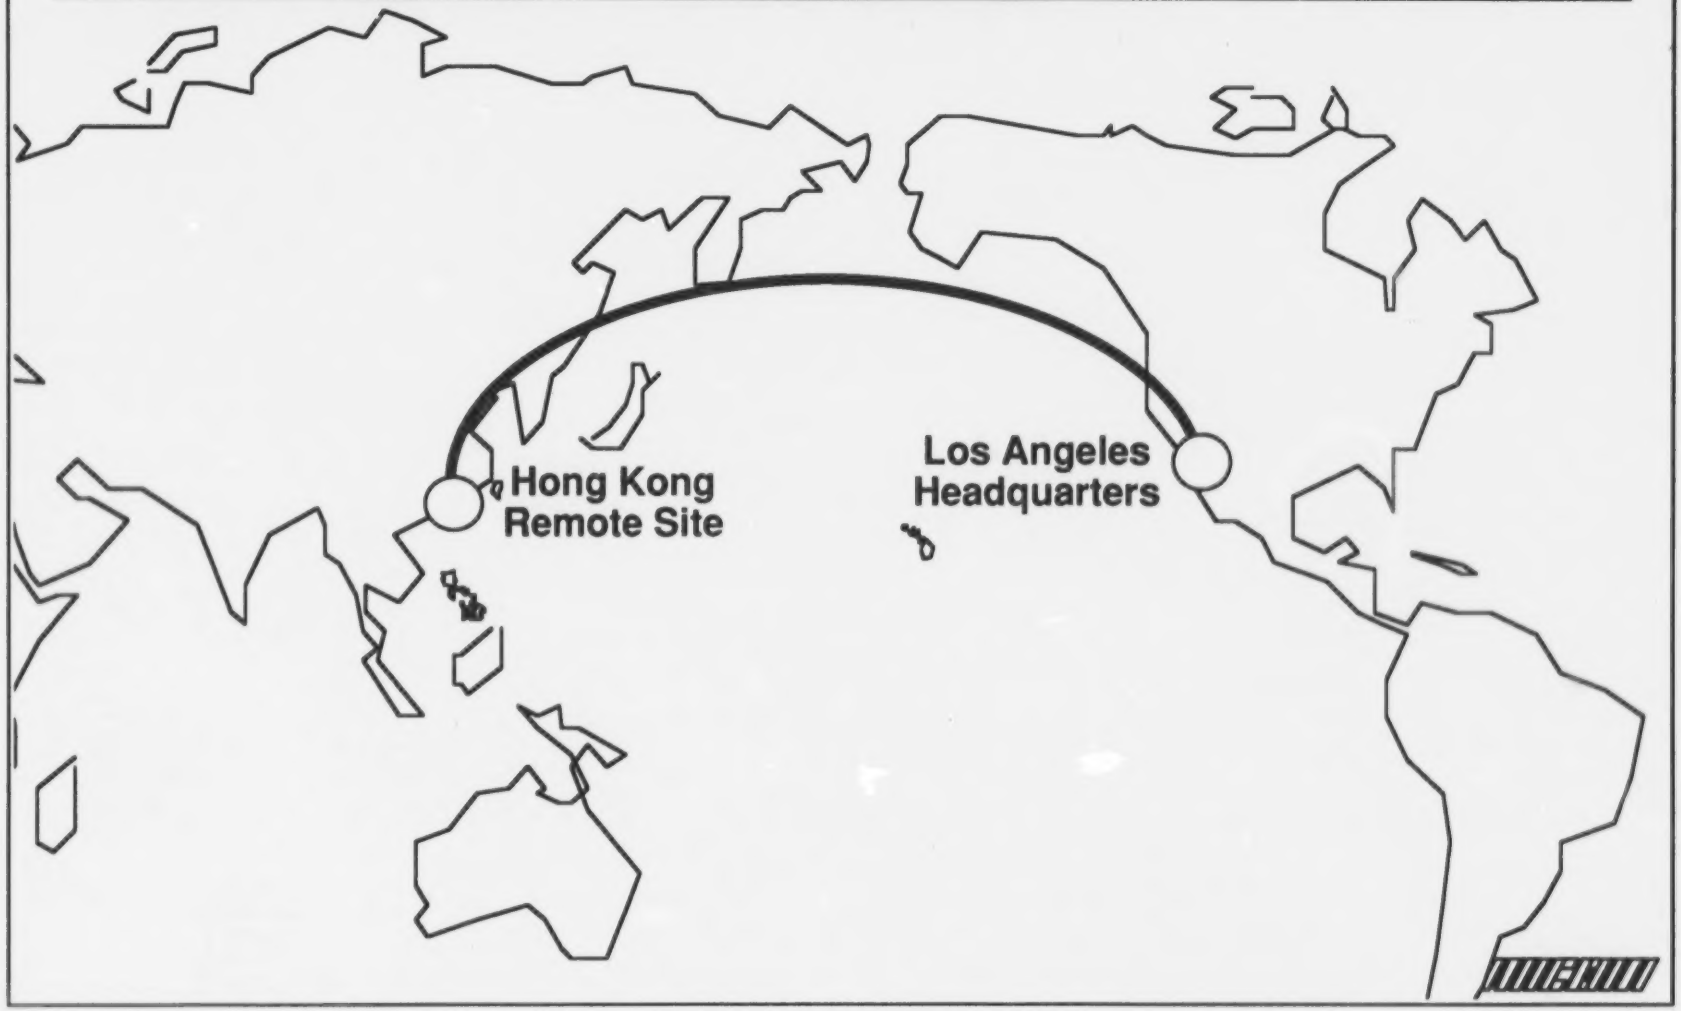
- **Example:** 32 Terminals at 9600 bps
  6 Voice/Fax Lines at 64,000 bps
- **With TDM Technology: Requires 691,200 bps**



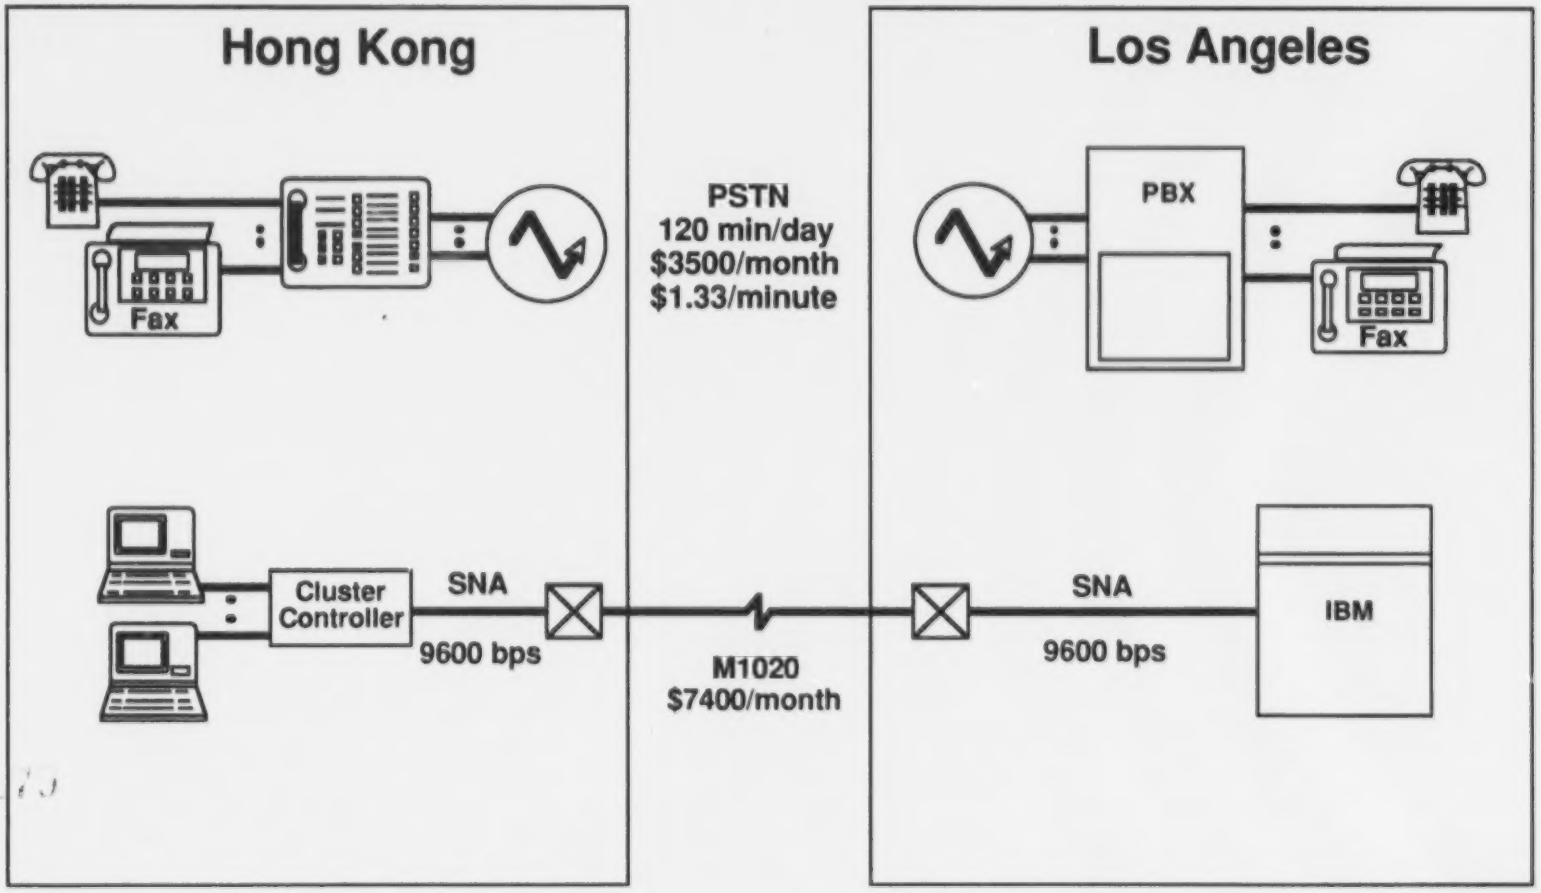
- **With New Technology: Requires 64,000 bps**



PAYBACK EXAMPLE AT 56/64 Kbps



BEFORE INTEGRATION



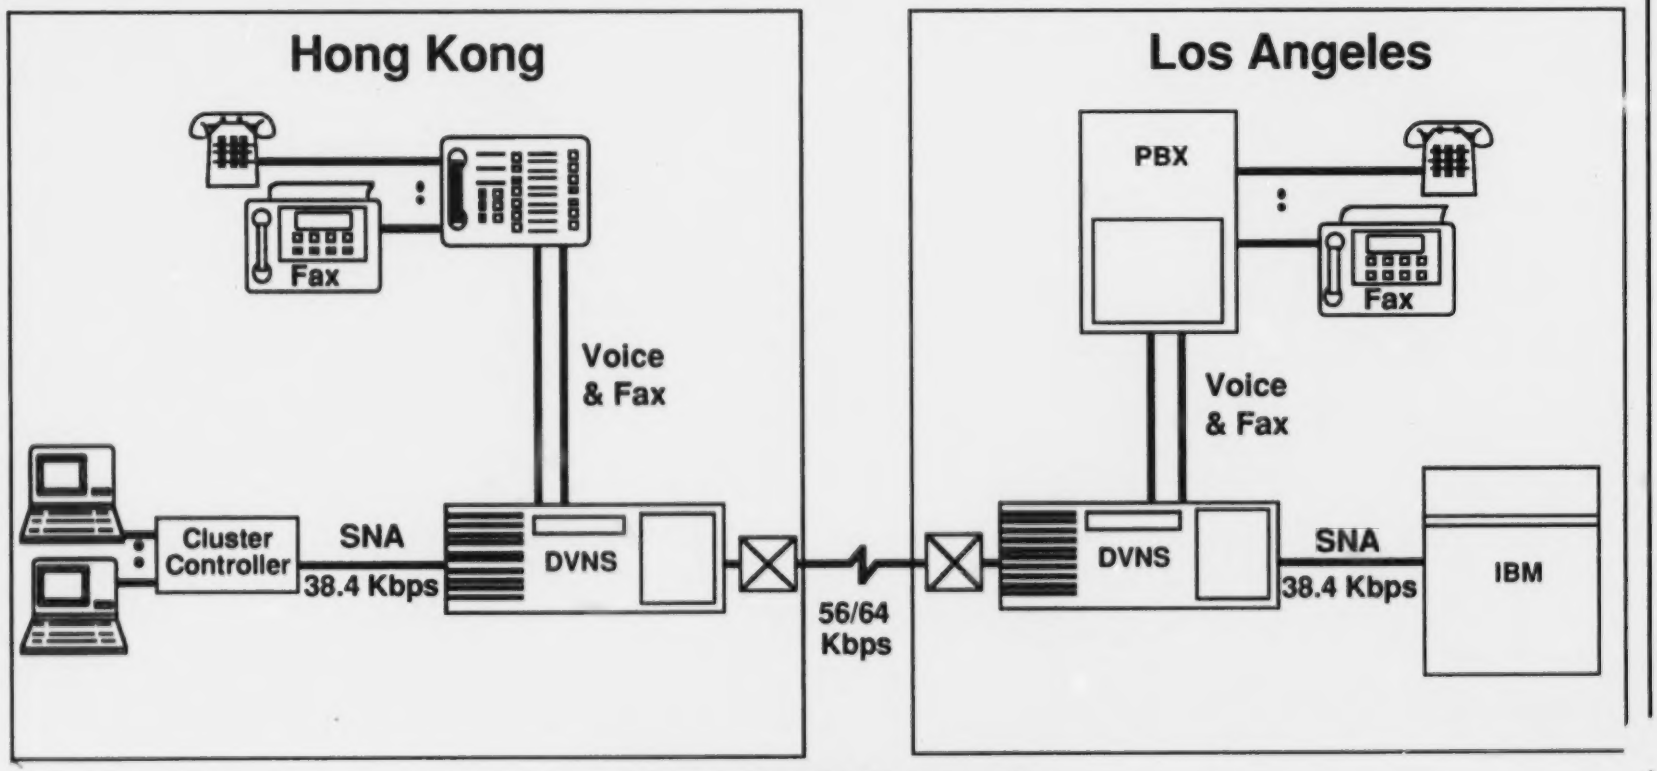
PAYBACK EXAMPLE LOS ANGELES—HONG KONG

- Voice and Fax Toll Calls of 120 Minutes/Day
  - Monthly toll charges are $3500/month
- M1020 Data Line Costs $7400/Month
- 56 Kbps Digital Line Costs $9100/Month
- DVNS Configuration:

2 Servers	$3,500
4 Voice/Fax Modules	4,400
2 Data Channels	INCL
Total DVNS Cost	$7,900

- Payback in 5 Months, Save $1,800/Month Thereafter
- DVNS Saves $22,000 Each Year

AFTER INTEGRATION



Save $1800/month
5 month payback
Data runs 4 times faster

DVNS IMPACT— THE RULES HAVE CHANGED

- Data/Voice/Fax/LAN Integration
  - For Small to Midsize Companies, Too
  - Low cost solutions using low speed lines
- New Technology
  - Speech and Data Compression
  - Automatic Fax Demodulation
  - Fast Packet Multiplexing
- New Bandwidth Plateau - 56/64 Kbps

TODAY'S PERCEPTIONS

"You need to be a large company and use T1 to integrate data, voice, fax, and LAN"

"I didn't know you could integrate voice and data over the same low-speed leased line — especially to my smaller remote offices"

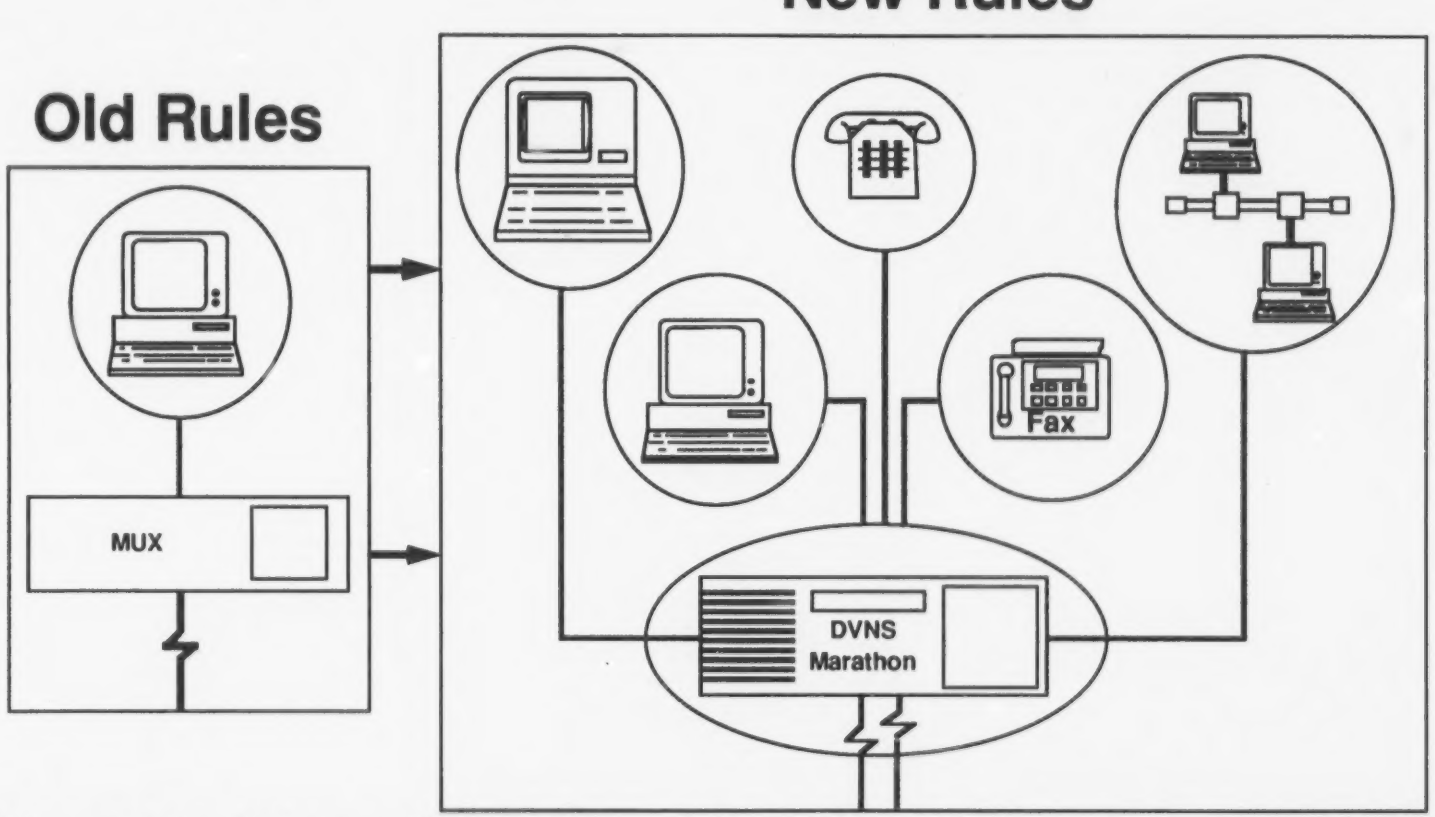
THE NEW RULES OF WIDE AREA NETWORKING



Affordable Integration of Remote Data, Voice, Fax and LAN

NEW INTELSAT EARTH STATION TYPE-APPROVAL PROCEDURES: LOWER COSTS AND SIMPLER IMPLEMENTATION

Calvin Harriott and Kenneth Dorvee
COMSAT World Systems
Washington, D.C.

ABSTRACT

COMSAT World Systems' (CWS') type-approval process is designed, primarily, to facilitate the rapid cost-effective entry of small earth stations into the INTELSAT global satellite system. The process ensures that any earth station, INTELSAT type-approved using CWS' procedures, accessing the system will meet the relevant INTELSAT standard and not endanger the integrity of system operations. For example, very small aperture terminal networks can be implemented on an international basis without the time-consuming and potentially costly process of detailed verification of each individual earth station in the network.

The CWS type approval process involves working with earth station manufacturers, vendors, or operators to determine the suitability of an earth station model for type approval. An earth station model is finally granted type approval after a series of design reviews, evaluation of manufacturing and quality control measures, specific functional and operational tests, and evaluation of test results. Purchasers and users of a type-approved model are subsequently allowed access to the INTELSAT satellite system without individual earth station verification testing.

Introduction

This paper presents an overview of the earth station type-approval process developed and implemented by COMSAT World Systems (CWS), the U.S. Signatory to INTELSAT. It also gives a brief analysis of the changes in the operating environment which provided the impetus for the type-approval process, including a summary of INTELSAT activities leading to its implementation. The U.S. Signatory's type-approval procedures are described, and their advantages, especially for small-diameter antennas, compared to the standard INTELSAT antenna verification and certification process, are presented.

Note that INTELSAT type approval cannot supplant requirements of administrations. For instance, in the United States, all earth stations must meet the requirements of Federal Communications Commission (FCC) Part 25 and be properly licensed.

Operating Environment Changes

Early satellite communications operation was defined by three basic characteristics: low-power satellite down-link transmission capability; analog FM transmission links, and large (up to 32 m), high-gain earth station antennas. In the INTELSAT system, these characteristics limited access to those entities that could provide the large "gateway" or multipurpose antenna systems. Today, however, there are many non-signatory users who own earth stations which are generally, though not exclusively, much smaller, simpler, and far less expensive than the original, or current, gateway designs.

Areas of concern for INTELSAT operation include interference to users of the INTELSAT space segment; interference to and from users of other satellite systems; excessive demand for transponder power caused by substandard antenna performance; and assurance that the earth station is capable of providing the required service quality. To preclude these problems, antenna owners/operators are required to demonstrate that new earth station antenna systems meet RF performance specifications. This is accomplished by conducting a series of defined antenna system verification tests to determine actual earth station performance in both transmit and receive operation. The complexity of the tests, and the antenna systems being tested, typically result in significant man-hour and resource expenditures for the earth station owner/operator, the signatory, and INTELSAT.

The typical cost in the United States for engineering support from an earth station vendor or integrator to an earth station operator to perform an INTELSAT on-site earth station verification is on the order of $10,000. This covers the cost of testing only; it does not include charges for necessary field adjustments or alignments if the earth station fails to meet the mandatory performance criteria.

If INTELSAT resources are used, the time normally required from receipt of an application to formal approval to

operate is approximately 13 weeks, assuming all goes well. Seldom does all go well.

Note that earth stations are approved in far less time if the required resources are readily available. A significant portion of the 13 weeks (8 weeks) is required to ensure availability of INTELSAT space segment and a communications system monitor (CSM). The U.S. Signatory competes with other signatories and INTELSAT operational requirements for the use of these resources, with INTELSAT operations taking precedence and signatories' requirements treated on a first-come first-served basis.

An owner/operator may make alternative arrangements such as using a domestic satellite (DOMSAT), which may reduce the time involved, but the basic cost of testing remains similar. In addition, costs such as those for the use of satellite transponders for testing (there is no charge for the use of INTELSAT space segment), the costs of transporting units to a test range, and the administrative costs of coordinating tests all add to the expense and time required to commission an earth station. However, in these situations the owner/operator has greater control over scheduling and performing tests than when using INTELSAT.

From the U.S. perspective, changes in the INTELSAT environment were driven by a number of technical, regulatory and operational factors.

Technical

Design and manufacturing advances in satellite and earth station technology have improved the performance of spacecraft, earth station antennas, and transmission techniques. Higher power satellite down-link capabilities, more efficient earth station antenna RF performance, improved receiver performance through the use of inexpensive gallium arsenide (GaAs) low-noise amplifiers (LNAs), and digital frequency-division multiple access (FDMA) techniques, made possible such new services as teleports close to urban centers, customer premises earth station (CPES) operation and Satellite News Gathering (SNG) using small earth station antennas down to 1.5 m in diameter. These options have made satellite communication an attractive and cost-competitive alternative to other communication media. The proliferation of earth stations means that their performance is even more a matter of concern for the overall administration of space segment operation and must be ensured. Also, finding ways to reduce the expense and difficulty of the required verification (of performance) testing on a per earth station basis becomes necessary.

The introduction of Ku-band transponders in INTELSAT satellites, through a new generation of hybrid satellites, enabled the operation of small Ku-band earth stations in urban areas. This is due to the more benign radio frequency interference (RFI) environment as compared to C-band. At the same time, this eliminated a major cost consideration, that of terrestrial access to C-band gateway type earth stations usually located in remote rural areas to escape terrestrial interference.

Regulatory

The regulatory changes that brought about the dissolution of the U.S. Earth Station Ownership Consortium (ESOC), which owned and operated the U.S. gateway earth stations operating in the INTELSAT network, opened the way for non-signatory ownership and operation of earth stations in the U.S. This trend is beginning to appear in other countries as well.

In April 1986, the FCC [1] facilitated the use of very small aperture terminal (VSAT) networks in the U.S. by liberalizing the licensing procedures for small earth station antennas operating in the 12/14-GHz frequency range. Concurrently, INTELSAT opened the door to type acceptance of earth station antennas but did not choose to mandate a process, leaving this responsibility to the various signatories.

Operational

Changes in INTELSAT's operational philosophy, the creation of new service classifications, and the development of tariffs for private-line services encouraged the growth of services such as International Business Service (IBS). Leased transponder services such as INTELNET (DATANET), television transmission and broadcast services, and the emergence of bandwidth-on-demand services such as short-term leases for special news events all became possible with the INTELSAT changes. This last category of service, bandwidth-on-demand, is still evolving.

All of the above factors lead to a relative explosion in the numbers and types of earth stations requiring access to the INTELSAT space segment. As shown in Figure 1, for the first 21 years of operation on the INTELSAT network the U.S. Signatory commissioned a total of 38 earth stations. In the last 6 years, applications for more than 360 earth stations have been processed by CWS. This number does not include receive-only (RO) terminals, as these obviously cannot cause interference to the space segment, although substandard sensitivity or gain-to-noise temperature ratio (G/T) could result in inferior performance or excessive demand on satellite down-link effective isotropically radiated power (e.i.r.p.).

Background

With the foregoing changes, the signatories' continuing responsibility to INTELSAT for operation of earth stations in their respective territories became significantly more demanding. Ensuring compliance with INTELSAT standards still depends primarily on performing verification tests for each individual earth station. In the era of few large gateway earth stations, this was not a major cost consideration. However, as the size and cost of earth stations were reduced, the cost of testing and certifying earth stations for operation on the INTELSAT system became a relatively significant percentage of individual earth station cost. Also, the time required to bring a new earth station into service became critical, given the competitive imperative for instant, or near instant, establishment of service links. Further,

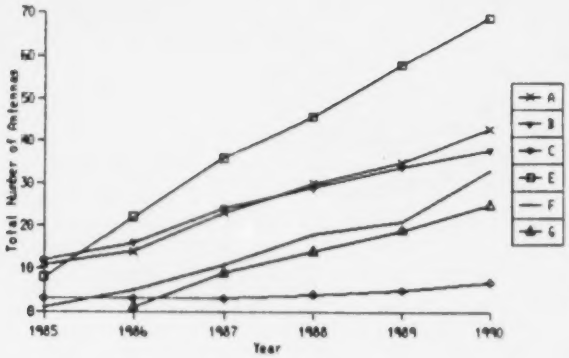


Figure 1. Cumulative Number of U.S. Earth Station Antennas by Standard for Each Year

the INTELSAT facilities which support earth station verification testing were stressed to the utmost by the volume of demand for their use.

Note that the provision exists for operation of an earth station in the INTELSAT system without the earth station having completed verification testing. However, this is used only in extraordinary circumstances and is granted for a limited period of time. A recent example of this was the provision of communication links to and from the Middle East during the Gulf crisis.

In response to this situation, two significant administrative actions led the U.S. Signatory to develop a type-approval procedure for earth stations accessing the INTELSAT system. In 1985, in a move to streamline the access process, the INTELSAT Executive Organ initiated a dialogue with the signatories regarding establishment of a type-approval policy for small-aperture antennas accessing the INTELSAT system. In April 1986, document OPSA 3-9-1 [2] was issued which addressed several aspects of the earth station approval process, including a general procedure for type acceptance of earth stations. The Executive Organ left the specific procedures to the individual signatories, but reserved the right to approve or disapprove earth station models proposed for type approval.

This started an iterative process among INTELSAT, the signatories, and various antenna system and earth station manufacturers and integrators which continues today. Using the type-approval procedure established by Inmarsat for ship terminals [3] as a guideline and in consultation with earth station antenna experts at COMSAT Laboratories, the U.S. Signatory drew up draft type-approval procedures designed to ensure the integrity of INTELSAT space segment operations while reducing the need to test every small aperture antenna, especially those used for VSAT or other multistation network applications. An important step in the evolution of the procedures was seeking out and incorporating input from U.S. antenna and earth station manufacturers. Other signatories such as Australia, France, Norway, Germany, Switzerland, and Colombia have used the same basic procedure to have antenna systems accepted by INTELSAT as meeting type-approval requirements. In a related step after discussions with U.S. VSAT manufacturers, the U.S. Signatory was able to obtain a relaxation in polarization discrimination requirements for a range of small earth stations.

U.S. Type-Approval Procedures

In theory, any earth station standard is a candidate for type approval. In practice, type-approval procedures [4] are directed mainly toward INTELSAT Standard D1, E-1, E-2, F-1, F-2, G, and Z earth stations. This is because practical aspects of antenna design tend to limit the reflector size and operating wavelength of antennas which can be fielded with confidence that on-site adjustment is not required. However, small antennas, which are the most suited to acceptance testing on a sample basis, are those most likely to be deployed in quantity and thus benefit the most from type approval.

Although early type-approval efforts emphasized antenna systems with a one-piece reflector design, antenna designs incorporating three or less segments have successfully completed the type-approval process. Antenna reflectors with multiple segments have been proposed, and one model with an eight-piece design is currently undergoing CWS type-approval testing.

To allow for maximum flexibility and to accommodate various entities such as antenna manufacturers, system integrators, and earth station operators, the U.S. Signatory's type-approval process has been implemented in a hierarchical arrangement. Currently, the procedures allow for the following three system combinations to be considered for type approval:

- The earth station model, which specifies the mechanical and electrical performance characteristics of all equipment and components making up a complete earth station system.
- The antenna system model, which specifies the mechanical and electrical performance characteristics of the antenna system, consisting of the antenna, mounting structure, and associated LNA.
- The antenna model, which specifies the mechanical and electrical performance characteristics of the reflector, subreflector, feed, mounting structure, and associated drive and pointing systems.

Each subsystem of a type-approved model is subject to performance analysis. Therefore, as more subsystems are included in the model the type-approval process encompasses more testing. Each manufacturer of a subsystem is required to fully participate in the type-approval process to ensure consistency, integrity of the manufacturing process, and quality control of their product.

The successful completion of a type-approval exercise is the result of close coordination and cooperation between the U. S. Signatory and the type-approval applicant. The sequence of events leading to the granting of type-approved status for an earth station model is as follows:

The Application - A statement of intent by the type approval applicant to the U.S. Signatory proposing a

1195

candidate antenna, antenna system, or earth station for type approval.

Phase I Testing—For this step, the applicant, under signatory guidance, develops and performs tests which demonstrate that the model meets applicable INTELSAT technical requirements. The tests are performed on a system which is identical to the production unit and are designed to verify the performance of the model to the maximum extent possible. They generally include subsystem tests and demonstration of their relationship to total system performance. However, it is acceptable to evaluate system performance to demonstrate subsystem behavior in cases where the subsystem performance cannot be measured directly. Also, the Phase I step demonstrates the margin of system performance above minimum requirements.

The applicant also identifies the operating environment of the model over which compliance with the standard is achieved. To the extent possible, the applicant provides the technical evidence which demonstrates these capabilities.

Once the Phase I test results have been analyzed and approved, the applicant and the U.S. Signatory jointly develop Design Review procedures and a Phase II test plan. This, again, is an iterative process that continues until both parties agree on the scope and general requirements of these steps.

The Design Review—Once the Phase I tests are completed and the results reviewed, the U. S. Signatory and applicant jointly participate in a design review. The process includes input from any subcontractors who provide subsystem equipment. The purpose of the design review is to demonstrate that the manufacturing process, quality control discipline, documentation, and assembly or installation procedures will result in a product consistently meeting the applicable *INTELSAT Earth Station Standards* (IESS) performance. This takes into account mass production and includes a review of field installation procedures to verify that proper performance will result without the need for on-site verification. Several iterations may be required before this step is satisfied. The output of this exercise is a Design Review Report, which is included in the technical documentation package for review and concurrence by the U. S. Signatory. This report, along with other technical documentation and accompanied by CWS' assessment of the candidate earth station's manufacturing and quality control, field installation procedures and system performance, a review of the process and procedures leading to this assessment and any special recommendations and comments, is formally submitted to INTELSAT following the successful conclusion of the entire type-approval process.

Phase II Testing—This phase is completed with the direct participation of the U.S. Signatory. The applicant performs functional tests of the model using an INTELSAT satellite, other space segment, or a test range. The method used is dependent on the earth station standard, the testing requirements, and the availability of resources and facilities. Range testing is the preferred alternative, as this provides the most flexibility in scheduling and performing tests. Normally, these tests follow conventional INTELSAT verification test procedures; additional tests may be added to evaluate added system options. Functional tests may also include "out-of-the-box" assembly or installation to demonstrate performance reliability in a simulated field environment. Several randomly selected production systems are tested to demonstrate performance. A single unit is disassembled and reassembled to verify repeatability and to compare performance with that obtained previously for this unit and for other units tested.

Following successful completion of the process, the applicant submits to the U.S. Signatory technical reports demonstrating full compliance with INTELSAT specifications. Following a thorough review, the U.S. Signatory certifies the system to the INTELSAT Executive Organ. It reviews the documentation supporting type approval and, if satisfied, assigns a type-approved designator. A type-approval certification listing the earth station standard(s) under which the model has been approved, a list of components or subsystems included as part of the approved system, and any restrictions applicable to this model are included with this approval. The approved model is added to the list of type approved earth station models in the INTELSAT network. This list is routinely provided to all INTELSAT signatories.

Modifications may be made to type-approved systems after consultation between the applicant and the U. S. Signatory, and discussion with INTELSAT. The modifications must be fully evaluated as to their effects on system performance, and any required re-testing of the modified system must be successfully completed. This process follows the general format of the initial type-approval process in scope, and the type-approval performance requirements must be met and demonstrated.

Follow-up testing of the type-approved model after certification can be requested by the INTELSAT Executive Organ any time deployed antennas appear to have degraded to the extent that there is evidence of resulting problems on the space segment. The U.S. Signatory also reserves the right to require follow-up tests to ensure the continued integrity of the manufacturing process and quality control.

COMSAT World Systems' Current Work With U.S. Vendors

Initial contact with U.S. vendors to introduce them to the type-approval concept started in 1986. Several meetings were convened to hone the process and to accommodate vendor concerns. However, following initial enthusiasm on the part of the vendors, there was a period of inactivity. Manufacturers and vendors were unfamiliar with, and possibly distrustful of, the process, and apparently had difficulty economically justifying the investment in cost and time required to obtain type approval in what they thought of as a limited market. At that time, U.S. earth stations in the INTELSAT network numbered less than 100, and the market was shared among a number of vendors. Therefore, the process remained at the discussion stage for a long time.

The first system was type approved by CWS less than 2 years ago. But since then, 12 systems built by U.S. manufac-

turers have successfully completed the process with the active involvement of three vendors and integrators. Interestingly enough, the first system was approved for use at an overseas location—Taiwan. Type-approval work is currently in process with a total of seven U.S. vendors and integrators.

Conclusion

Earth station type approval in the INTELSAT environment is still in its infancy. The U.S. Signatory believes this process is very important to the continued viability and growth of INTELSAT. Communications pundits predict that satellite communications will increasingly incorporate more and more VSAT type networks. This is likely, as communication niches of the future that capitalize on the strengths of satellite communications may depend heavily on VSAT communication links, and CWS is endeavoring to stimulate growth of such networks. Earth station type approval will be a significant factor, making implementation of such networks possible in a timely and cost-effective manner.

The type-approval process has started and CWS hopes that this will encourage other manufacturers and vendors to get involved, if only to protect their market share. The net result will ultimately benefit service providers and end-users through lower costs and faster network implementation. It will also reduce administrative and operational costs to the U.S. Signatory and INTELSAT. The decision to implement earth station type approval may very well be one of the most significant decisions in INTELSAT's history.

Acknowledgments

The authors would like to acknowledge the assistance of Calvin Cotner, Director of Technical Liaison and Analysis, CWS, who was instrumental in getting the process off the ground and providing insight into the development of this paper; to Dr. Ernest Ekelman of the Earth Station Antenna Department, COMSAT Laboratories, whose expertise was invaluable in making the process work, and U.S. manufacturers for their continuing support of the development of INTELSAT type approval.

The authors would also like to thank Betty C. Alewine, President, CWS, Carl M. Jeffcoat, Vice President, Operations and Engineering, CWS, and Richard Skroban, Director, Earth Station Services, CWS, for their encouragement and support.

Introduction

Introduction

More and more, today's companies are trying to capitalize on technology to gain sustainable competitive advantage. They realize that, as the rate of technological change increases, their products and services must be more advanced, faster, better and easier to use than their competitors' products and services. However, the question with which companies are often faced centers around how to convert their new products or technologies into business opportunities. They need a process to assess where the technology fits in the marketplace, to size the market, to see how fast the market will evolve and to come up with the most effective market penetration strategy.

New technologies emerge from a number of places. Sometimes they are the result of a tightly focused R&D effort to find a solution to a specific set of customer needs. However, in a surprising number of instances, new technologies emerge as an unexpected by-product of R&D efforts. These are not directed at solving a specific set of marketplace needs; rather, they appear to have a potential fit into markets and applications that are outside of the company's scope of business. Every large R&D laboratory has its list of unexploited technologies because technologists are rarely able to translate technology into business opportunities. This is true for several reasons:

- New technologies are rarely one-for-one replacements of existing technologies; they usually cut diagonally across more than one application
- Most technologists look to applications that optimize the technology. Often, the best marketplace fit is not the best technology fit
- Technologists want to put their technology into the largest market opportunity. Frequently, the best place to insert the technology is in niched market applications where end users place high economic value on the technology

1193

Technology Screen

Technology Screen

A process called the Technology Screen is particularly valuable for companies that want to assess where a new technology fits into the marketplace. This is especially true in both of the following situations:

- When a product or technology has been developed and a company must identify its market—end-user groups possessing needs that the product or concept can satisfy at an acceptable cost
- When a product or concept has entered R&D but is not yet fully defined and the company must clearly understand the needs of target end-user segments in order to effectively continue development and launch of the product

The key variables that must be considered in both of these situations are buyer needs (segment prospective buyers based on the product features and benefits they require), economics (use a value analysis to determine the buying segments for which it makes economic sense to adopt the new product or technology) and time (determine the most realistic adoption timetable for buying segments and gauge both near- and long-term market opportunity).

Each of these variables should function as a screen to allow companies to further define their product launch strategies by answering questions such as: How big is my market? Where is my market? When will my market develop? How do I reach my market?

Screening the market is an iterative process. A non-linear approach is especially valuable in the environment of ambiguity in which new product teams work. It allows them to learn as they go, sort out what is and is not important and adapt their approach during the process. Each screen may be applied and reapplied as the product or technology is modified and redefined. The universe of

1209

- what broad performance requirements does each application segment have?
- how do those requirements relate to system configuration and functionality?
- what is the variance in requirements across the application segments?

- Which channels should Proxim pursue in developing partner relationships?

The company's team of management, strategic marketing, engineering and finance specialists believed they had a differentiated product. However, they were unsure of the best markets and opportunities to target and pursue with the product. They needed market-based information to develop the optimal go-to-market strategy.

The first decision Proxim's team needed to make was where to place the initial focus. Given a broad capability, it would have been very costly for Proxim to evaluate the total universe of product options and market segments. An initial series of brainstorming sessions was used to develop a straw man for Proxim's radio-based, micro-programmable controller called the NanoController. Next, the group generated several hypotheses concerning where NanoController applications might exist.

A series of discovery interviews were conducted with experts, end users and vendors of competitive technologies to validate the hypotheses. As a result of the screening process, 18 application candidates were identified, which were further condensed into five application families, each with a set of distinctive characteristics on the functionality of the NanoController in the application, the type of solution offered and the benefit sought. Each screen—Needs, Economics and Time—revealed crucial information for Proxim's team.

Needs Screen

- Potential end users' business characteristics

Market information on these issues will point cross-functional teams to the major benefits or capabilities of the product or technology and those end-user groups with the greatest and the least need for each. This information can be plotted on a matrix to indicate those segments where the product or technology is or is not a fit. In analyzing the matrix, teams develop hypotheses by asking questions of themselves, such as: What common business characteristics within this group make them a fit, and what common characteristics exist within the low-probability group? Eventually, discussions will point to some segmentation hypotheses.

These hypotheses are confirmed by opening the interviewing process to include a larger portion of the universe within these perceived segments. Screened end users are then plotted on the matrix, confirming or denying previous segmentation hypotheses.

Interviews are conducted with those individuals who fall into the low/low-probability quadrant to determine what it would take to move them into the high/high-probability quadrant. The information helps teams begin to chart a migration strategy and possible timing of near- and long-term market opportunity.

The Needs Screen often tells companies along the way that the functional parameters—what the product does—must be redefined and tested again with buyers. At the same time, it helps them determine if what the product does not do is a major obstacle.

After completing the Needs Screen, companies can also determine how to communicate with buyers about the product in ways the buyers will find meaningful. For instance, Proxim learned through interviews conducted with experts, end users and possible competitors in the

Economics Screen

Economics Screen

The Economics Screen examines only those prospective buying segments that the Needs Screen has identified as potential fits for the new product or technology. The next step is a value analysis to find out if the product or technology makes economic sense for these buyers. This is accomplished through additional interviews that entail asking the market how it cost-justifies the new product or technology.

The Economics Screen reveals economic issues by asking prospective end users questions that help determine:

- How the need is being addressed today, and at what cost
- What will happen to the cost of today's solution over time, and why
- What the cost of adopting and using the new technology or product will be
- What other "value" it will bring to the prospective buyer, and what form this value will take
- If the new product or technology is economically advantageous for the prospective buying segment to adopt now or in the future
- If there are any other technologies that impact the application and economics of this new technology
- How the market defines the competition

Once the market reveals these keys to cost-justification, teams can define those segments for which the product or technology is the cost-effective, optimal solution. They can ask additional questions to gain a sense of adoption timing for each segment, an indication of how the product fares versus the competition's and how and why the product would be accessed. Possible questions include:

Time Screen

Time Screen

The Time Screen looks at those buying segments that have passed through the Needs and Economics Screens because they are likely to adopt the new product or technology. The first two screens have confirmed that there is a business opportunity and enough economic value for the market to develop. The Time Screen defines the rollout timetable for the new product or technology for each previously identified segment as it helps answer through additional interviews:

- Is the buyer actively trying to solve a problem that the product or technology can address?
- What organizational changes would have to take place in order to make adoption possible?
- Based on the answers to the first two questions, how long will it be before the prospective segment begins to adopt? How quickly will the segment be penetrated by the new product/technology?

The Time Screen research process allows teams to plot segments along a problem-solving continuum, which includes those actively trying to solve the problem that the product or technology addresses (action), those shopping for solutions (cognizance) and those who may have a problem but do not recognize this fact (precognizance).

After plotting the segments along this continuum, teams can then develop, test and confirm hypotheses related to:

- The barriers between each continuum phase
- The percentage of each segment that falls within each phase
- What it will take for each group to pass through the barriers and move along the continuum

The Time Screen helps determine how fast the market will develop, how long it will take for elements of the product

How to Use This Tool

How to Use This Tool

The screening process should be used to define new products or technologies and the most effective launch strategies. Companies should build on this analysis to develop strategies that:

- Assess the viability of the new products or technologies by buying segment and identify short- and long-term applications and opportunities
- Identify the near-term market and estimate the migration of market growth
- Establish benchmarks that must be met for estimated growth to occur
- Identify priority market segments and reveal buying behavior
- Define specific activities and support required for each segment during the buying process
- Provide a model for resource allocation to the new product or technology launch
- Profile target buying segments' key characteristics and offer a screening methodology to continue to identify these high-probability buyers
- Identify other potential new product or technology opportunities based on unmet needs of buying segments
- Create a data trail that can be used to adapt the product or accelerate adoption

Clearly, if companies are to use technology as an advantage, they must adopt a sophisticated marketplace discovery process. As in Proxim's case, marketers and planners should take an active role in organizing a team to look critically at the problems and opportunities inherent in new products or technologies. Involving a number of key players is crucial, as the implications of new product development cut across many functional areas without

About
Frank Lynn & Associates, Inc.

About Frank Lynn & Associates, Inc.

Solutions to business challenges like these can be found in the marketplace. We would like to work with you to address specific issues you might face. We can bring you tailored solutions, designed for the markets you are trying to reach, based on their requirements. And we have the track record to prove that this market-driven strategy works.

Since 1973, Frank Lynn & Associates, Inc. has helped companies like yours examine their market segments and develop approaches to reach them effectively. We bring, to each engagement, a process of analysis and conceptual tools that help clients understand customer needs and expectations as well as marketplace dynamics. Given this foundation of understanding, client companies can transform their perspectives and become successful market-driven organizations that meet or exceed client satisfaction requirements by identifying sustainable competitive advantages. Our approach stresses qualitative research and starts with an in-depth understanding of buyer criteria and competitive forces.

We allow for active management involvement without overburdening a client. Our solutions are designed with sensitivity to our clients' internal capabilities, and many clients adopt elements of our tools and processes for evaluation and future planning.

Our expertise is grounded in our understanding of customers—when they buy, what they buy, how they buy—and the role of distribution channels in meeting their needs. We build on this foundation to reveal a multitude of ways our clients can achieve strategic success. We have the experience and business savvy you are looking for. We offer you:

BRINGING PRODUCT TO MARKET

Brian G. Holton
KTSF-TV, San Francisco, USA

Good afternoon. It is great to be here and I'm honored to be with such a distinguished panel. I also wish to thank Michael Berg for being our moderator today, and I wish to thank all of you for being here today as well.

Today, I wish to focus my talks on how our company brings television programs from the Far East to the San Francisco market, and how we wish to send programs to overseas markets and the types of problems we encounter doing this. I wish to share with you what our television station sees for the future, considering all the current and evolving technologies and inform you that KTSF and others like her are currently a vital link in the communications food chain. Ultimately, I hope to shed some light on how we can work together to distinguish and identify the best alternatives for the transportation of video products overseas so our company can bring the product to market.

As I said, KTSF is part of the communications food chain as you are. You are able to provide transportation vehicles for the transmission of information over great distances and in great volume, via satellites, fiber optics, Teleco, etc. We, in turn, select the types of information needed for our market and deliver this product to the home, via our television station in the San Francisco Bay Area. We then solicit advertising support to pay you for your services and, in the end, Mr. and Mrs. Wong (the end-user) purchases the advertisers' product. For our company, this conference offers the opportunity of exploring and finding the most efficient way to bring the product to market so our advertisers can advertise affordably; Mr. and Mrs Wong can afford to buy the advertisers' product; I can pay you and make a modest profit.

As Michael informed you, I work at an independent television station in the San Francisco Bay Area. KTSF is not affiliated with any other television stations in the United States and we are owned by the Lincoln Broadcasting Company, a California Limited Partnership. We are a family-owned television station and our programming focus is televising overseas programming to the culturally diverse communities of San Francisco and Northern California.

We broadcast twelve different languages weekly and our main emphasis is the Asian Market. We broadcast in Chinese (Cantonese and Mandarin), Japanese, Korean, Tagalog, Vietnamese, Greek, Italian, Farsi and several others. Our programming runs the gamit from variety and movies to dramas and news, with news playing the most vital role. In many cases, we gather information in bits and pieces from around the world, and we package and produce programs for our television market and, in some cases, we syndicate the properties we produce worldwide.

News and information from overseas is the single most important aspect of our programming line-up. It so important we began the first live Chinese newscast in the United States in 1989 and by all accounts, this program has been a smashing success in San Francisco and Northern California.

In the San Francisco Bay Area, Asians comprise nearly 17% of the market and most are recent immigrants. Therefore, much of our business deals with Far East nations and KTSF is the primary source of news and information for many of these Asians in the Bay Area.

KTSF also produces and broadcasts several specials such as the Chinese New Year's Parade, The Miss Asia of America Beauty Pageant, The Chinese Martial Arts Championships and Masters Exhibition, and several others. We broadcast and syndicate these programs worldwide. In the case of the Chinese New Year's Parade, which is the largest nighttime parade in the world, and one of the largest celebrations of the Lunar New Year outside of Mainland China, it is a spectacular event and we produce and broadcast this property in two languages simultaneously. From a visual standpoint, this program is exceptionally delightful with all of its color, pageantry and tradition, and, although I cannot speak any of the languages we broadcast, I certainly enjoy the pictures.

In the case of the Chinese Martial Arts Championships and Masters Exhibition, we produced the property in three languages: English, Cantonese and Mandarin and in 1990, we syndicated the property in English nationwide on Prime Network, a cable sports network reaching nearly 19 million homes in the United States.

Currently, we employ several modes of transport to acquire and send programming to and from overseas. These include the use of domestic and international satellites, airliners, faxes, telephones, UPS, Federal Express, microwaves and human messengers. In fact, we would even use the Pony Express or Morse Code if we thought we could send or receive the information we had to in an economical and expedient manner. Our selection of transport vehicles is based upon three primary needs: costs, speed and dependably.

For example, with News we need to be concerned with the timeliness of a story, but at the same time, we must consider the costs. If a story has significance, we might pay the tremendous costs of Intelsat, but if we are purchasing movies and dramas, perhaps we would receive by Pony Express. For the specials we produce which go live, we employ a redundant set of microwaves, Teleco, domestic uplinks and our own terrestrial delivery system to bring the product to market.

At this time, I would like to give you a couple of examples of projects we currently have underway and future projects we are reviewing.

For our Chinese Newscast, news sources comprise nearly 25% of our budget of which the transportation costs, not the license fees, make up a significant portion of these cost. I want you to understand the problems I face as a broadcaster doing business between the United States and the Pacific Rim and may be you will be able to help me bring my product to market in a timely, dependable and cost-effective manner.

Currently, to receive our news sources, we use faxes from overseas reporters, live phone interviews, subscribe to several news entities such as UPI, Bay City News and CNN, and we acquire video footage from Hong Kong, Taiwan and Mainland China. From Hong Kong, we receive the footage via air freight and it is about two days old by the time we go to broadcast and the video reports from Mainland China are sometimes as much as two weeks old. From Taiwan, we receive same day news via international satellite. Of our three daily Japanese newscasts, two are received via international satellite and one by airplane. Our Korean and Italian Newscasts are received daily via international and domestic satellites.

Right now, we are working on a couple of projects where the cost and timeliness of delivery is one of the major obstacles. For example, we have a newscast from the Philippines we are attempting to acquire, but the costs for international satellite time, uplinks and downlinks are cost-prohibitive. We will probably run on a one or two day delay employing the airlines, however, during the Philippine elections scheduled for May this year, we will attempt to go live.

We are also working on a program with our sister station in Taipei and will need to establish several communication networks for video and voice. This program is a co-venture between the stations and involves time critical video reports from several nations around the Pacific Rim which will need to be edited together rather quickly to be ready for timely broadcast.

The problems we face in attempting to get or send information overseas is the cost and the cumbersome logistics. For example, for international satellite feeds, we need to get matching orders, one from our side and one from their side to get the satellite time. If you ever tried to explain to your overseas counterpart at 2:00 a.m. Pacific Standard Time what a matching order is in foreign language, you can just about forget the timeliness of that news report. I keep thinking the process must be simple and I just need to study a bit more but I have yet to find the process of arranging international uplinks, transponder time and downlinks easy. This arrangement problem is then exacerbated when I then need to take the international feeds and transport them to our station. Problem number one hits when on the West Coast in my area, there are only two international downlink receive sites. This requires us to arrange microwaves hops to our station, or, in some cases, we actually send messengers by car to pick up tapes. The second problem occurs when we find out these international receive sites can only record NTSC formats. One time we had to

borrow a converter, drive two hundred miles to the receive site, install the converter, and instruct the personnel how to convert from PAL to NTSC. This particular example demonstrates an irony in the speed of communications today. We could send a signal thousands of miles in seconds, yet it took about six hours to transport this signal just 200 miles! In essence, if I am going to employ this new technology, we need to find a way to make the process simpler.

The overall speed of international communications plays a large role in our ability to get information to market quickly. You know in 1903 then President Theodore Roosevelt sent a cable around the world and it came back in twelve minutes, today one would think that is ancient history, but in my case above, that was quick.

My point is, the development and use of all this high technology sometimes misses it mark because it does not consider or cannot deal with the total communications food chain. As you know, today there are many businesses and people involved in the transportation and interpretation of information, and one must attempt to look at the real problems facing those who underscore and bring the product to market. I call it marketing. Is marketing sales? I don't not think so. I look at marketing at how I can solve my customers' problems, not what I can sell them. In order to understand my customers problems, I need to study what it takes him to do his job, I need to be very familiar with his business, I need to walk in his shoes to understand his needs, in essence, if I ran his business would I buy my services? Example: We worked for a long time attempting to get a small retail account and we tried to talk with him many times but he was always busy, on the telephone, running the store, etc. When we finally got a meeting with him, he informed us he was trying to hire someone to assist him, but he just did not have the time to interview people and he was afraid to hire just anyone since he'd had bad luck in the past. The first thing we did was write him a job description for the position, posted the position through our referral system and had our Personnel Director discuss with him what questions to ask when hiring. He hired someone in about one month and we got the account.

As I stated before, transportation of information in an economical, dependable and timely manner has not only changed our world but has become a necessity for survival, and will become common place, like a telephone. History tells us that wars have been won and lost and governments have risen and fallen because of the timely transportation of information and to whom this information was provided. The Gulf War was won not only because of military might but in great part, won due to surveillance and the transportation of this information to the generals in the theater of operations. The events of Tiananmen Square in 1989 and the recent breakup of the Soviet Union were due in great part to the dissemination of information.

My job is to determine what is needed and desired by my market; my market happens to be the Pacific Rim. We create and use products from overseas and send the same. Our job is to bring the product to market in the most cost-effective and efficient manner so that the end user/consumer of the information can afford the same.

Our company is a user of your technology and there are many more like KTSF. I suggest that the days of only large players in the international information delivery business such as AT&T governments and the military are lessening. Today, there are three international type networks in the United States, many non-secular programmers wish to go overseas from the United States, there are at least four televisions stations on the West Coast who are in the international program business and two more which are seriously considering going international, and, of course, many today are concentrating on the European market for video distribution.

As you know, we are approaching a globable village, or as Walt Disney said, "It's a small world after all." Transportation of information is changing our world. When someone thinks of San Francisco they think of the Golden Gate Bridge and Chinatown. But if you look at it from a little different perspective, you can the Golden Gate bridge analogous to Ellis Island and Chinatown not as a town but as a city. These new Americans have families overseas and wish to know what's happening in their homeland, and families overseas wish to see and hear their loved ones in the United States, (example, Taiwan for talk). People today and of tomorrow will have more choice as where to live or visit, and consequently, the miles separating family and culture will be mitigated by the speed and efficiency of communications, however, the cost, dependability and logistics need to get better.

With possible Teleco entry into the distribution of products, compression, DBS, and the multiplexing of Cable TV, new players will enter the arena of distributing the product to the market. Some television stations fear these new technologies such as DBS and compression, and although they will change the way we do business, KTSF Television sees some opportunities for growth.

We believe the free-unencumbered development and use of technology will allow for greater competition and, thus, enable the consumer or end user of the product to prosper which is necessary fuel for the communications food chain. We plan to take advantage of opportunities presented in this conference to enhance our companies' commitment to serving the diverse culture of the San Francisco Bay Area and Northern California and if God willing, produce a modest profit.

I thank you for your time and I hope that we will work together to bring the product to market efficiently, dependably and economically.

Thank you.

1211

ECONOMIC AND TECHNICAL CONSIDERATIONS OF A GSO GLOBAL MSS (TRITIUM)

Pacific Telecommunications Conference
January 12-15, 1992
Honolulu, Hawaii

Dr. George Hrycenko, Dr. Klaus Johannsen,
Patrice Louie, and William Lucas
Hughes Aircraft Company, Space and Communications Group

Summary

This paper reviews a study of an advanced geosynchronous orbit (GSO) mobile satellite system (Tritium), which offers an alternative to the recently advocated low earth orbit (LEO) operational proposals. The study illustrates that the improvements featured by LEO mobile satellite system (MSS) configurations can be better provided by GSO communication relays and at a substantially lower cost. In fact, on a per-channel basis, geosynchronous systems offer similar service that is an order of magnitude less expensive than low earth orbit alternatives. The issue of hop delay is not a significant factor when assessing market demand since the majority of potential users will have, at best, limited access to substitutes. The inherent flexibility of GSO systems provides a unique ability to adjust to evolving market demographics. These factors allow geosynchronous MSS to offer the most affordable service that satisfies the public demand.

Furthermore, the study concludes that advanced GSO MSS capabilities can be implemented with more conventional technology, which offers longer life and less operational complexity. These GSO system service features not only offer equivalent performance and substantially improved reliability, but also provide compatibility with equivalent low cost mobile terminals proposed for LEO's with the same global connectivity. Most important, the advanced GSO system features improved spectral efficiency over currently operational MSS configurations and over some of the new LEO contenders.

Introduction

The Tritium mobile satellite concept is a geosynchronous approach to providing global cellular radio communication. It features mobile-to-mobile user and mobile-to-fixed user communication. Tritium achieves global coverage by three GSO satellites, separated 120° in orbit; each satellite covers its part of the earth with up to 160 beams. The inbeam and interbeam connectivity is provided by Ku-band backhaul links and by earth based switching. The power spectral flux densities at the earth's surface produced by the Tritium satellite beams will not exceed the maximum values set forth by the Radio Regulations. The maximum capacity per satellite is 30,000 links and the total Tritium system capacity is about 90,000 duplex circuits. This capacity is placed where it is needed, namely over populated areas, whereas over 80% of the advertised total Iridium capacity of 285,000 circuits is placed over largely unpopulated areas or is unusable. Therefore, the three satellites of the GSO Tritium system have nearly 50% more effective capacity as the 77 satellites of the Iridium LEO MSS.

1212

System Economics

In an effort to compare the relative strengths and weaknesses of low earth orbit (LEO) and geosynchronous orbit (GSO) satellite systems for mobile communications, attention must be given to the economic considerations governing their construction and launch. It is true that each LEO satellite is significantly cheaper to build and launch than a GSO satellite for systems of similar capability. Yet, given the fact that low earth orbits require many more spacecraft for complete earth coverage, and because LEO satellites last approximately 40%-50% as long in orbit as GSO satellites, the total number of spacecraft over the system's useful life will be substantially more. This generates a much higher cost to build and operate a LEO system over a similar period than a comparable GSO system.

Arguments have been made about the benefits of the "learning curve" when building large quantities of essentially identical spacecraft. We have found that although such downstream savings do occur, they tend to be relatively small and are often overshadowed by the huge investment in research and development. In fact, Motorola estimates that the average nominal flyaway cost of the replacement satellites for Iridium do not generate any recurring savings on average. If the non-recurring costs are applied to the initial constellation, the learning curve generates no more than a 20% savings[1] .

Table 1 illustrates the relative costs of building and launching different types of communications systems; two low earth with polar orbits and one geosynchronous. It is obvious that, on a per-unit basis, LEO spacecraft are substantially cheaper to build and launch. In addition, launch costs to geostationary transfer orbit are, on a per pound basis, roughly double those to low earth orbit. The extra weight of kick motors and hydrazine fuel boosts the total launch cost for each GSO spacecraft to many times the cost of each LEO satellite. However, because a GSO system requires only 2%-3% of the total number of LEO satellites over the life of the system, the aggregate costs to manufacture and launch a geosynchronous constellation are substantially less than Iridium and only double those of Aries, a system with far less capability.

When comparing costs per usable channel, it is even more readily apparent that a GSO system is, by far, the most economical solution. A major benefit espoused by LEO proponents is the fact that only low earth orbit systems offer total earth coverage. Because the highest latitudes are out of the range of visibility of GSO satellites, these systems cannot offer coverage near the poles. We have found, however, that, except for some marginal airline traffic over the northern polar regions, less than 0.5% of the world's population (primarily over Russia) is excluded from geosynchronous coverage[2]. Of the greater than 99% of the addressable market positioned within the realm of GSO systems, only about 5% exists over the oceans and about 3%-5% over the polar regions (roughly 1% from maritime traffic and approximately 7%-9% from intercontinental airline traffic). LEO systems, by their nature, must cover the globe with uniform capacity as they travel over the entire surface. Geosynchronous satellites can be tailored so that only a small percentage of the available channel capacity sits over the oceans. In addition, the proximity of low earth orbiting spacecraft over the poles causes significant beam overlap at the higher latitudes. Because of this, only 56% of Iridium's cells are turned on at any one time[3]. Other low earth, polar orbit systems suffer similar inefficiencies. Consequently, the combination of polar beam overlap and redundant ocean

TABLE 1. LEO-GSO System Cost Comparison

PARAMETER	IRIDIUM LEO	TRITIUM GSO	ARIES[1] LEO
# of Satellites	77	3	48
Standby Satellites	7	1	4
Total # of Satellites per Life Cycle	84	4	52
Satellite Design Life (Years)	6	12	5
# of Satellites per 12 Years	220	4	136
Cost per Satellite ($M)	$13.4	$150.0	$3.0
Cost of Fleet for 12 Years ($M)	$2,948	$600	$408
Dry Weight per Satellite (lbs.)	950	6,200	275
Launch Cost per Satellite ($M)	$6.0	$194.0	$2.9
Total Launch Cost ($M)	$1,317	$776	$394
Insurance Rate	7%	18%	7%
Insurance Cost ($M)	$299	$248	$56
Total Space Segment Cost	$4,564	$1,624	$858

orbit systems have a total number of usable channels that is from 40% to 99% less than a comparable GSO system. Consequently, the cost per effective channel to implement and operate a LEO system is significantly greater. Table 2 illustrates this case in point.

In addition to cost, there are some practical tradeoffs that must be addressed. Hop delay is a seemingly unavoidable problem with geosynchronous range. However, as Motorola defines the addressable market, potential users will consist of those in need of emergency communications, those who have no available mobile service, those who have no telephone service at all, and those whose only mobile satellite service comes from geosynchronous spacecraft[2]. It is a well known fact that people who do not have access to a particular service and yet who desire that service will pay for its implementation and use, even though the quality is inferior to better, but unavailable substitutes. Every segment described above, except for the last, defines just this situation. In fact, users of Intelsat request a circuit change only 12% of the time when presented with an alternative[3]. Therefore, from a business viability standpoint, we have not yet seen a compelling argument demonstrating the negative effects of hop delay on the mobile satellite business. Demand should not be appreciably affected in the projected markets serviced by these global systems. Since a GSO system can be implemented less expensively, it should indeed be built since the savings will go to the consumer by way of lower service costs.

TABLE 2. LEO-GSO Cost per Channel Comparison

PARAMETER	IRIDIUM LEO	TRITIUM GSO	ARIES[1] LEO
Channels per Satellite	3,700	30,000	50
# of Satellites	77	3	48
Total System Capacity (Channels)	284,900	90,000	2,400
Reduction for Beam Overlap	0.56	1.00	0.57
Reduction for Ocean Coverage	0.29	0.90	0.29
Capacity Used by Maritime and Airline Traffic	1.10	1.01	1.10
Channel Usage Efficiency	18%	91%	18%
Effective System Capacity (Channels)	50,900	81,810	436
Total Space Segment Cost ($M)	$4,564	$1,624	$858
Total Space Segment Cost per Channel	$90,000	$20,000	$2,000,000

The second and perhaps the most important factor to consider is the inherent flexibility of a GSO system. The fact that the marketplace is dynamic and unpredictable warrants a set of satellites that can alter beam configurations and power requirements as demand concentrations change. A geosynchronous spacecraft can be tailored to the needs of the market. Intra-beam capacity can be altered from the ground without affecting the balance of the system because each cell remains stationary. LEO satellites must maintain constant power levels and channel capacities since they move over different areas of the globe. If local market demand evolves beyond the capacity of the satellites to absorb the changes, a LEO system will not be able to efficiently serve its customer base.

Finally, if the market does not develop as quickly in certain regions of the world, a GSO approach allows the phased implementation of the system by launching spacecraft only where they are immediately needed. This facilitates a workable system with only partial coverage. A LEO system, on the other hand, must be nearly fully launched in order to avoid unacceptable delays and sporadic connectivity. This increases the required initial investment to launch the business, even if demand does not warrant that level of available capacity.

Instrumentation

Hughes has recently studied a GSO MSS system, Tritium, which reflects the cited economic advantages. Nominal satellite locations for Tritium are 100° west, 20° east, and 140° east. These positions guarantee that all continents are covered, and that visibility crossover for a 5° elevation angle occurs at high latitude (62°) (Figure 1).

[1] Aries FCC Filing, June 3, 1991.

1215

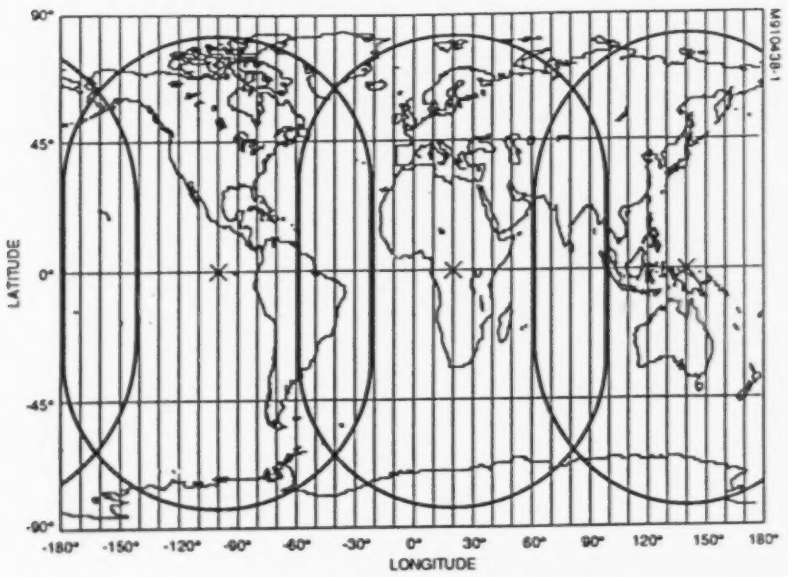

Fig. 1 Tritium system coverage

The global view from synchronous altitude is about 18°. With beams of 1° beamwidth, which can be obtained by use of a 55-foot antenna, visible earth coverage is achieved with about 290 beams. If only land masses are to be covered, the number of beams is 120 to 130, depending on which part of the world the satellite is located. Satellite weight and power constraints limit the number of beams to about 160. For full earth coverage, some ocean coverage beams are combined to form beams of 2° to 3° (Figure 2).

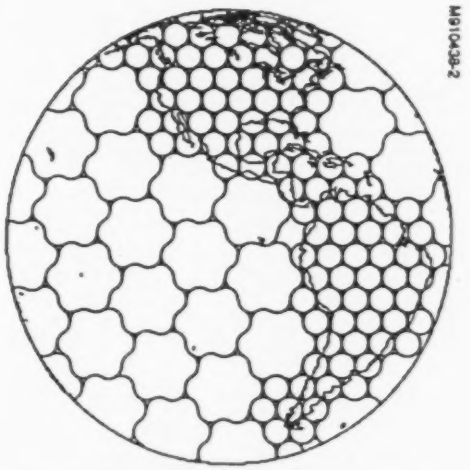

Fig. 2 America coverage beam zones
for satellite location at 100° w

1216

A satellite that provides cellular radio service by so many beams requires a lot of independent signal paths that do not cause mutual or intercell self-interference. Difficult functions of a multibeam satellite are diplexing of transmit and receive frequencies, interbeam connectivity, and RF-power distribution. Diplexing for a large number of beams can run into weight and space limitations. Therefore, one approach to avoiding diplexing would be to transmit and receive at time-interleaved intervals on the same frequency; this approach would also avoid passive intermodulation. Of course, it would require exact timing of the total network and digital burst transmission. But, with solid state power amplifiers (SSPAs), there are instrumentations available that assume some of the diplexing functions. The SSPAs produce low levels of intermodulation and cancel the out of band transmission, thereby avoiding the active intermodulation that falls into the receive band. Besides active intermodulation, there is passive intermodulation (PIM), which may fall into the receive band. Based on preliminary studies, it has been concluded that a certain amount of PIM can be tolerated and that dual frequency operation, i.e., separate frequencies for transmission and reception, is preferable over single frequency operation and precision transmission timing.

One of the most important decisions in making up a repeater architecture is to choose the method of interbeam switching. After careful system analysis, it has been concluded that with up to 160 elemental beams, the onboard processing required for complete interconnectivity is too complicated and the switching and processing functions have been relegated to the ground. The implication, of course, is a long transmission time delay for a full duplex system (about 600 ms) because the signal travels four times the length of the geosynchronous altitude.

The distribution of RF power in the various beams is another vexing problem. It would be advantageous if all the amplifiers could amplify all the signals, but this requires complex Butler matrices and fixed delays among antenna elements. Instead, it has been decided to have independent amplifiers (one per feed element) where the amplifiers have constant efficiency and use power only according to the number of applied carriers.

CDMA was selected as the preferred access approach since it offers the greatest frequency reuse and voice channel capacity. Also, CDMA is less susceptible for both multipath and multibeam interference, partly because interference adds mostly as noncoherent noise and partly because it can use a higher rate FEC and, therefore, a low Eb/No, without widening the bandwidth. Although FDMA has historically been preferred, today's microchip technology favors CDMA.

The mobile user who tries to make a connection has to ask for service on one of the network control channels, which is unique for any beam. By transmitting on one particular control channel, the network control center knows where the vehicle is located and will allocate a voice or data channel in that particular beam. If a mobile user is to be contacted, one has to know the position of the vehicle. For this purpose, its access code will be broadcast on all beams or in certain beam sectors where the user might be situated at that time. The user's response will indicate its position. Also, the position of mobile users can be obtained either by the user's forwarding position information, or by having the network control center monitor the control channels and memorize the last position. For network control and interlinking, all global and local area network control stations will be interconnected by Ku-band links.

CDMA and Mainlobe Interference

Studies show that CDMA mainlobe interference is the primary source of degradation and sidelobe interference is of secondary concern. Since CDMA must use a wide bandwidth for interference rejection, one cannot slice up the total transmission bandwidth into small pieces. If one uses a 14 MHz band, each beam has the same frequency, and a user at the crossover of three beams suffers the interference from 3n-1 friendly users. In the satellite visibility crossover zone the

interference would double unless different polarizations are used on adjacent satellites. If the band is divided into three frequencies, adjacent beams do not have the same frequency and the user at the crossover zone of three beams suffers only the interference of n-1 friendly users. However, the WT product, i.e., the transmission bandwidth times the bit period product is lower because the spread bandwidth W has been divided by 3 and, consequently, the interference rejection is reduced. Analysis shows that it is better to use the larger bandwidth and accept the 3n-1 interference than to reduce the bandwidth. Since each beam uses the full 14 MHz, about 64 beams will fill up 1000 MHz. To accommodate 160 beams 2500 MHz are required, which must be partitioned among several Ku-band earth stations residing in different geographical areas and operating on a dedicated Ku-band spot beam.

CDMA Links

The L-band and Ku-band beam EIRP budgets are given in Table 3. The edge of earth L-band beams have a 4 dB gain defocusing loss. Table 3 also shows the expected gain over temperature ratio (G/T) budgets of both L-band and Ku-band receivers.

TABLE 3. TRITIUM EIRP AND G/T BUDGETS

Parameter	L-band EIRP, dBW		Ku-band EIRP, dBW
	Edge Beam	Center Beam	
HPA output power, dBW	9.0	10.0	14.0
Output losses, dB	–1.3	–1.3	–2.0
Antenna gain, dB	41.3 (EOC)	41.3 (EOC)	35.0 (Center)
Scan loss, dB	–4.0	0.0	0.0
EIRP per beam, dBW	45.0	50.0	47.0 (max)
	L-band G/T, dB/K		
	Edge Beam	Center Beam	Ku-band G/T, dB/K
Antenna Gain, dB	41.0 (EOC)	41.0 (EOC)	35.0 (Center)
Scan loss, dB	–4.0	0.0	0.0
System temperature, dBK	28.0	28.0	28.0
G/T, dB/K	9	13	7.0

CDMA link performance calculations represented in Table 4 show that with a rate 1/3 FEC and a WT product of 34.5 dB all CDMA links can support 125 to 250 carriers per beam, depending on beam pointing, and that CDMA provides a high link margin (4 dB) against its own low Eb/No of 4 dB. The CDMA links also indicate that it is best to use the widest bandwidth for optimum signal to noise ratio. It should be noted that signals transmitted

= 13-10-17 = –14 dB

1219

from cell to cell are going up in L-band, then down in Ku-band to the network switching center, where signals will be demodulated and remodulated and noise will be removed. Therefore, there is only one hop of effective satellite link noise to be accounted for. The L-band downlink carrier to spectral noise density received through a 4 dB gain antenna is 45 dB Hz. The edge beam power flux density in 4 kHz on the earth surface is -154 dBW/m^2, which meets Radio Regulation requirements at 0° to 5° elevation. The center beam produces a power flux density of -149 dBW/m^2 per 4 kHz, which is 5 dB below the maximum allowable limit of -144 dBW/m^2 per 4 kHz at high elevation angles.

The number of channels per beam can also be calculated from the following equation:

$$m_{CDMA} = \frac{(No/Eb)\ WT}{a\left[L_{im}(1 + \frac{1}{K})\ A_{fb} + (N/C_T)_d + L_{im}\ (N/C_T)_{Kuup}\right]M}$$

where

(N_o/E_b)	=	Required noise density to bit energy ratio
(N/C_T)Ku up	=	Noise to total power ratio of the Ku-band uplink
$(N/C_T)_d$	=	Noise to total power ratio of the downlink
WT	=	RF bandwidth X bit-period
L_{im}	=	1.04 degradation in detection due to IM (at 15 dB NPR)
K	=	10 Gaussian fading factor
A_{fb}	=	3.4, main lobe and sidelobe interference factor
a	=	Voice activation factor (0.4)
M	=	Link margin

Tritium-CDMA Communications Payload

The Tritium-CDMA repeater is shown in Figure 3. In case of the forward link, Ku-band signals are transmitted from several master control stations (MCSs) within two 500 MHz bands (per beam), in two planes of linear polarization in 14 (15.6) MHz slots, and are downconverted to C-band. From C-band they are further downconverted to L-band, where filters will select a 14 MHz band associated with each L-band beam. After filtering, signals will be fed to the transmit chain, which consists of channel control unit/linearizer and a 10 W SSPA. The amplified signals are then routed to the L-band diplexer and from there to the L-band feed. On return, L-band uplink signals, collected by a single beam, are amplified and filtered by 14 MHz filters. Then, the elemental beam bands of 14 MHz each are converted to C-band. Up to 64 bands of 14 MHz are combined by an odd-even output multiplexer, after which separate bands of 32 X 15.6 = 500 MHz are upconverted to Ku-band and transmitted to the MCSs, which are in different parts of the satellite viewing area. For the purpose of interconnecting all network control and gateway stations and for interlinking, there is a Ku-Ku-band interconnection and distribution network. At the MCS, inbeam and interbeam switching and other operations which are necessary to clean up transmission are performed.

One building element necessary for the success of a Tritium-like satellite mission is the HPA with constant efficiency. Constant efficiency means that over a wide dynamic input power range the HPA requires a dc power proportional to the applied input power. Thus, when amplifiers do not require the allocated average dc power, the excess is available to other amplifiers, which may have

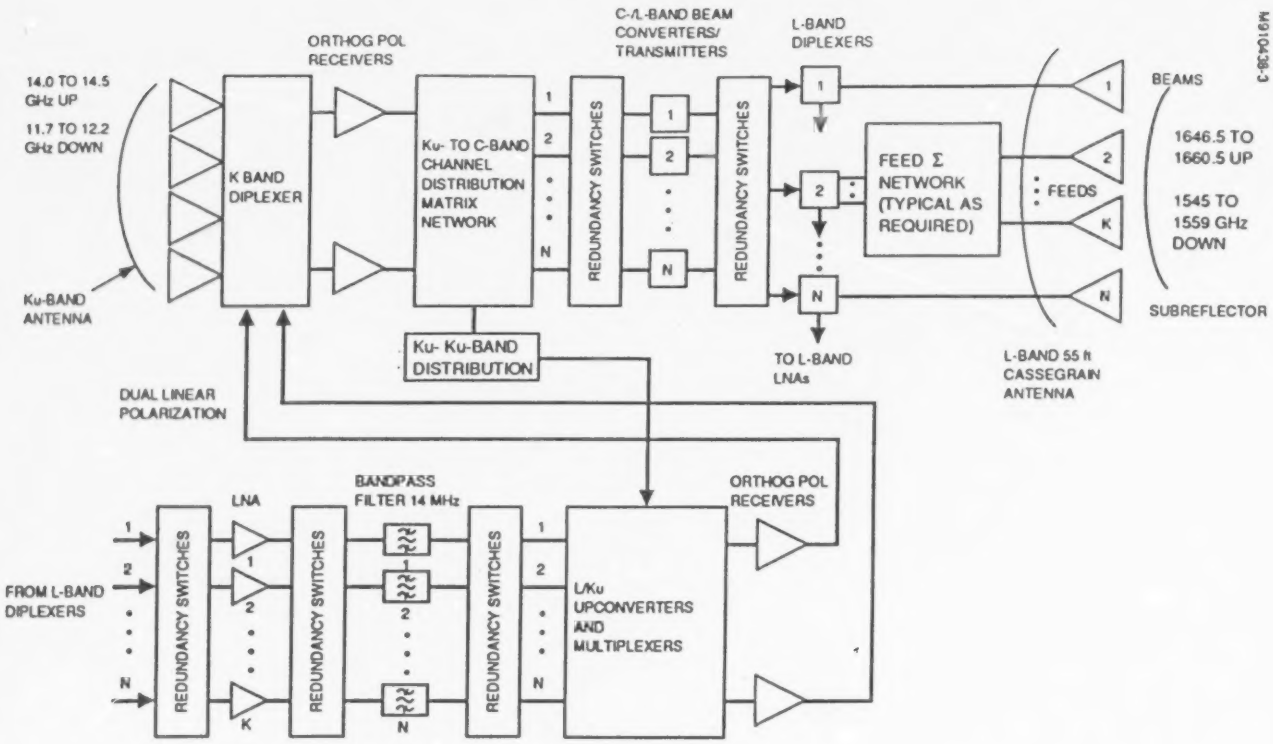

Fig. 3 Transponder

a higher carrier demand. Thus, there is a limited dc power transfer available from those amplifiers with little traffic to those with above average traffic. The center beams have a 5 dB dynamic range margin before their flux density limits are reached.

The L-band antenna consists of a 55 feet cassegrain reflector, which is attached to the body-stabilized Hughes HS 601 bus, and a subreflector, which is held in place by a tripod. The Ku-band antenna is mounted on the other side of the subreflector. The reflector is constructed of a wire mesh, which permits sunlight to reach the solar panels.

Tritium System

The link calculation shows that 125 mobile voice links of 4.8 Kbps can be supported by beams at the edge of the satellite visibility zone and 250 links can be supported by beams at the sub-satellite points. The Ku-band link is laid out for the average expected traffic of 160 beams or 160 X 187.5 @ 30,000 carriers. This requires a total Ku-band width of 160 X 15.6 = 2500 MHz. If this bandwidth is distributed among 10 gateway stations, each station has to transmit on its Ku-band link less than 250 MHz.

The payload weight and size is such that an Ariane 5 launch vehicle is required. A sketch of the Tritium satellite is given in Figure 4.

1221

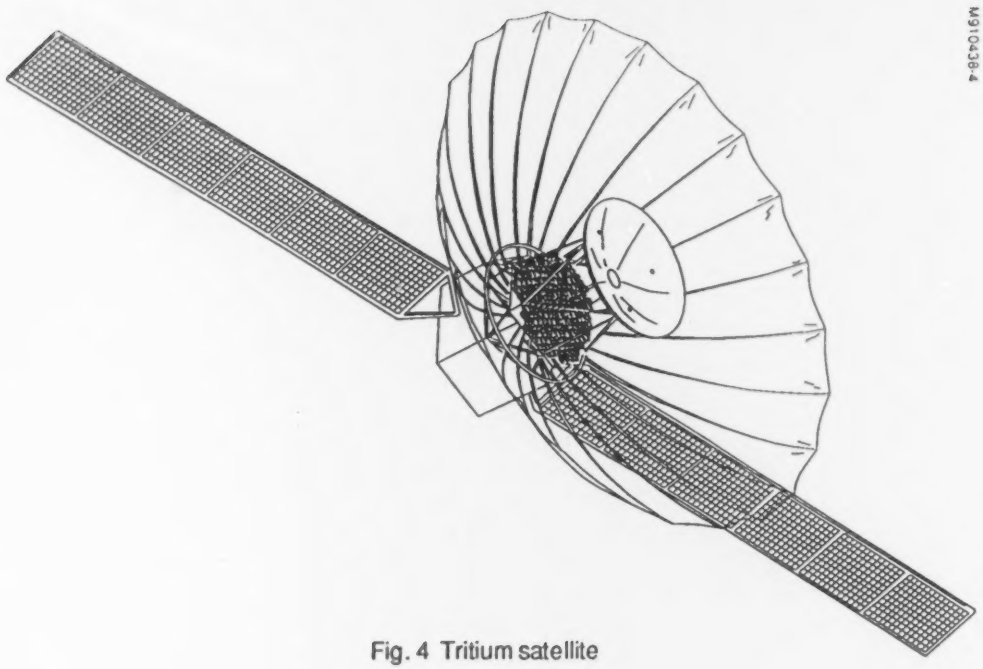

Fig. 4 Tritium satellite

In summary, the main Tritium features are the following:

- Augmented body stabilized HS 601 bus (6 panels)
- 55 feet L-band cassegrain antenna
- 160 L-band beams (N)
- 1646.5 to 1660.5 MHz mobile uplink
- 1545 to 1559 MHz mobile downlink
- 14 MHz total L-band bandwidth
- 14 MHz per L-band beam
- N X frequency reuse
- Interbeam communication
- Constant efficiency L-band SSPAs
- 30,000 mobile channel capacity per satellite
- 90,000 total Tritium system mobile channel capacity
- Ariane 5 launch vehicle
- Mission life 12 years

Conclusion

It is evident that a GSO system provides a more economical solution than LEO for mobile satellite communications. A global system using geosynchronous satellites is within the possibility of today's technology. The allocation of scarce frequency spectrum to service providers must be restricted to those who can best serve the needs of the public. It is therefore difficult to justify the obvious waste of resources, both spectral and financial, by constraining MSS to LEO systems. The most sensible alternative may be the implementation of geosynchronous mobile communications.

Global Networks
The Challenge of Creating a Global Network

Hiroshi Ichihara
President
Kokusai Denshin Denwa Co., Ltd. (KDD)

Socioeconomic changes in the world make the countries in the world more and more interdependent on each other. Telecommunications are required to play a catalytic role to develop this trend further. KDD is making an effort to meet this requirement by offering to customers end-to-end services. This paper describes how KDD is aiming at achieving this objective.

1. Introduction

The changes taking place in today's world are truly revolutionary. The tearing down of the Berlin Wall was one of the most dramatic in a series of events that led to the easing of East-West tensions and political transformations whose repercussions will be felt for decades, if not centuries, to come. At the same time, the increasingly "borderless" activities of corporations everywhere have ushered in a new era of globalization and growing interdependence in every aspect of business and economics. As a consequence, we are witnessing an expansion in the scale and scope of human activity that is unprecedented in history. Inevitably, the spotlight is now on communications in the true sense of the word. This, in turn, is accentuating the importance of international telecommunications, which have always been the primary means by which people have communicated over international boundaries.

KDD's response to these dramatic events has been to initiate the development of a global network designed to provide end-to-end customer support. I would like now to take a closer look at some of the actual steps we are taking.

2. Streamlining the International Trunk Communications Network.

There are two types of international telecommunications networks, satellite and cable, but in my talk today I shall focus on the transpacific submarine cable network. The bed of the Pacific Ocean already accommodates many submarine cables, as you can see from the first figure. Of these, optical fiber submarine cables have played a particularly significant role in handling the rapid increase in telecommunications traffic across the Pacific. In April 1989, KDD and twenty-nine other telecommunications carriers from fifteen countries around the globe joined together to begin operating HAW-4/TPC-3, the first optical fiber transpacific submarine cable. On a 64 kbps conversion basis, its capacity is equivalent to 7,560 circuits, making it the core of the current transpacific network.

However, the rapid increase in the volume of telecommunications has made it necessary to construct a new cable, TPC-4, which is scheduled for completion in October 1992. This optical fiber submarine cable will also have a very large capacity: on a 64 kbps conversion basis, its capacity will be equivalent to 15,120 circuits. As I am sure you know, optical fiber submarine cables have higher quality and larger capacities than conventional coaxial cables, so they have become an indispensable means of meeting the rapidly growing demand for telecommunications capacity across the Pacific Ocean. Nevertheless, the astonishing increase in transpacific telecommunications traffic means that even when the new cable mentioned above comes into operation, there will not be sufficient capacity.
For this reason, plans for the construction of TPC-5CN are already well advanced. TPC-5CN will be constructed of high-volume optical fiber submarine cables providing, on a 64 kbps conversion basis, a capacity equivalent to 60,480 cir- cuits in a two-pair configuration connected in a loop. In fact, the TPC-5CN's design incorporates

a revolutionary new concept - the self-healing system - which is illustrated in Figure 2. When a conventional submarine cable breaks down, we have to rely on satellite circuits or other cables for back-up until it is repaired. In contrast, each cable in TPC-5CN has its own independent back-up one on cable. By using two pairs for the circuits, the spare pair can take over for the first pair should it break down. Constructing the cables in a loop configuration allows transmissions to be switched to other cable on the loop should faults develop in both pairs.

Because the system permits instantaneous switching through the same transmission medium, it allows the provision of a secure and highly reliable network. Any future plans for laying optical fiber submarine cables are bound to place as much emphasis on security and reliability as on capacity.

Ordinarily, the optical signal transmitted inside the cable attenuates with the distance it travels, so that at set intervals it must be converted to an electric signal and regenerated. This requires submersible repeater. KDD has developed the technology to simplify repeaters in such a way that they amplify the attenuated optical signal as light without converting it to an electric signal. Because these simplified repeaters have fewer components, they are expected to provide greater reliability and allow larger signal volumes to be transmitted. Naturally, these repeaters will be used in the TPC-5CN cable. More details of the new optical amplifier will be given at another session.

When, constructing an optical fiber submarine cable, it is important to increase the reliability of the cable itself, but more important is its maintenance; the maintenance system which enables rapid repair and quick restoration of the traffic when breakdown occurs. KDD is presently building a new cable ship, the KDD Ocean

Link, which is scheduled in commission in February 1992, in addition to the KDD Maru which KDD presently uses for laying and maintaining submarine cables. She will carry the latest cable-laying equipment and a large-capacity cable tanks that will allow her to lay about 4,500 km of cable at one time. She will also be made highly maneuverable so as to facilitate the laying and repair of cable under the harsh ocean conditions of the North Pacific.

KDD has thus adopted an overall approach to building and improving the international trunk network which not only ensures that sufficient capacity is in place to handle telecommunications traffic, but also provides safer, more reliable circuits with an established maintenance system.

3. Improving the Domestic Telecommunications Network of the corresponding countries

When international telecommunications are seen as end-to-end services, it is obviously important to take the domestic network of the corresponding countries into consideration as well. The condition and status of domestic networks vary widely from country to country. In some countries, expanding or enhancing domestic networks to meet customer demand requires such vast sums of cost that a single enterprise cannot possible provide the finance. KDD is active here, too. As mentioned at PTC '91 last year, KDD, AT&T and the Ministry of Posts and Telecommunications of People's Republic of China are working together on the PRC Digital Network Project, for example. International telecommunications between Japan and China are currently handled by an Intelsat satellite and by the Japan-China submarine cable. Demand for high-quality digital transmission is growing among the users in China, however, the cable is expected to reach full capacity by the mid 1990s. It is thus imperative that the domestic and international telecommunications

networks be improved.

The PRC Digital Network Project was designed to meet this need. As illustrated in Figure 3, the first stage of the project calls for the use of local distribution radiowaves (LDRs) that employ digital microwaves to provide direct links between buildings in which customers are concentrated and an IBS urban gateway earth station installed on the roof of a Ministry of Posts and Telecommunications building. Digital leased circuit services will be provided via the Intelsat satellite over the Pacific Ocean.

This project will enable high-quality international digital transmission paths to be established via satellites in a short period of time. By redirecting international traffic that was previously handled on the domestic telecommunications network to these new links, the scheme will do much to reduce the burden on the domestic network. Services are expected to begin in the very near future.

As an extension of this project, the second phase calls for the construction of a Japan-China optical fiber submarine cable, which is scheduled to go into operation offering full-scale digital transmission services between Japan and China at the end of 1993.

While each country is basically responsible for building and enhancing its own domestic networks, one of KDD's goals is to contribute by making its technology available to countries that need it.

4. Services Provided with over the enhanced networks

Telecommunications services are faced with the task of satisfying a rapidly diversifying range of customer needs. Simply providing transmission routes does not meet the demand for full end-to-end services. To cope with the situation, KDD has adopted a number of

approaches, particularly with regard to corporate customers whose needs are especially diverse and sophisticated.

It is becoming increasingly clear that in order to operate in the borderless international market, today's businesses require high-capacity networks that provide real-time global links around the clock. At the same time, as they begin to use telecommunications in a more sophisticated manner, the construction of an efficient corporation network is an important part of any corporation's business strategy. As a result, corporations are not only demanding safer, more reliable networks, but are also moving toward integration of voice, images and data in a multi-media environment.

Another key trend in the creation of corporate telecommunications networks is "outsourcing." Corporations are finding it makes sense to concentrate on the areas of business where they are strongest, and entrust the implementation of networks and systems to the telecommunications providers who possess the necessary advanced technology and know-how. To meet this trend, KDD offers a line-up of the services called "KDD PLANS" which provide customers with comprehensive support for a wide range of networks, as shown in Figure 4.

As part of these services, KDD recently started offering the integrated network management service PLAN-M. Network monitoring equipment installed on KDD's premises provides total systems management and maintenance for customers, end-to-end, between Japan and abroad. PLAN-M deals with breakdowns speedily and makes it easier to control and analyze service quality. The SYSTEM-PLAN network service, on the other hand, lets customers use a system constructed on KDD's premises to build their own made-to-order system, while the PORT-PLAN network service provides a ready-made network by connecting the required customer cir-cuits to a system

on KDD premises. As part of another service, PLAN-H, KDD provides space on its own premises for customers who want to build a network with their own telecommunications equipment, and monitors, operates and maintains the equipment on the customers' behalf. Finally, under PLAN-E, KDD makes use of its own expertise in a consulting engineering service to support customers designing their own networks.

By using these services, customers can create more sophisticated networks in shorter timeframes with greater safety. Combining the services increases the benefits of implementing networks that use integrated management, thus enabling KDD to provide finely honed services that meet customer requirements exactly. Many of KDD's customers are already enjoying the benefits of these enhanced services.

At the same time, KDD is introducing new features to meet demand for more sophisticated capabilities in public networks. Using the optical fiber submarine cables and digital satellite technology described earlier, KDD now offers international ISDN service to 11 countries, including the United States, Britain, France, Australia and Singapore, with service areas to be expanded in the future. KDD's next step will be the introduction of broadband ISDN service which should help satisfy the growth in demand expected to result from heavier traffic, such as in highquality audiovisual communications.

By providing an array of databases in the network, KDD can also provide services that offer higher added value. KDD already provides intelligent network services such as Auto-Credit Card Call and Free-Phone Service. Most recently, it has started providing international Virtual Private Network (VPN) services. These services allow customers to "tell" the network how they want to pay charges, dial destination numbers, and so on. Although these services are still at a rather primitive level, we

consider them an important first step toward full-scale intelligent network services that include UPT service.

These endeavors are designed to transcend the ultimate dream of "face-to-face" telecommunications by providing tools that help people and implementing a global network that is intimately intertwined with human activities.

5. Global Carrier Cooperation

One critical factor in the programs and endeavors I have discussed to this point is the vital importance to the implementation of a global network of international cooperation and linkages between carriers. Obviously KDD cannot do it alone.

For international end-to-end telecommunications, the carriers in the originating and destination countries must work together. There are two possible types of carrier tie-up classified in line with the implementation of a global network. The first is characterized by the construction of the trunk line networks themselves, such as optical fiber submarine cables, or the establishment of carrier tie-up in the implementation of ISDN. An example of the second is the provision of services by groups of multiple carriers under joint brand names. This has been a particularly promising method of expanding new services and is making a major contribution to the globalization of such new services.

One service that KDD offers using the latter format is "one-stop shopping," which enables customers to integrate any requirement to a single contact point of carriers within the framework of the international leased circuit service and many customers have made use of this service. The Joint Network Initiatives (JNI) Project has been started since last year. JNI is a joint effort between AT&T, British Telecom, France Telecom and KDD to set up an

international telecommunications network that provides worldwide support to multinational corporations. Customers who wish to implement an international network employ the four telecommunications companies to put together a lateral, joint project team that provides circuits, delivers, maintains and operates equipment, and manages the network. This system guarantees end-to-end telecommunications within the four countries, integrates all points of contact when the network is set up, and delivers higher quality services with a shorter set-up time. Spain's Telefonica and Germany's DBP Telecom are also going to join the project. Further joint projects with overseas carriers are also under consideration at KDD.

In addition to this type of tie-up, KDD works through the KDD Group's overseas subsidiaries, as illustrated in Figure 5, to provide end-to-end customer support in the form of consulting and other services.

In the context of implementing a global network, it is also vital not to overlook the importance of technical assistance to developing countries. Cooperation with developing countries is an essential element in the planning, creation and extension of the telecommunications infrastructure to ensure greater universality and compatibility in the sphere of international telecommunications. KDD has long been active in such assistance and will continue to work with developing nations to improve their international telecommunications.

6. Conclusion

To conclude, KDD is working toward the construction of a global network through the many projects in which it is involved. These include the building of a trunk line system for domestic and international communications that incorporates maintenance and operational functions, responding to corporate

demand for more sophisticated services that utilize these networks, incorporating more intelligent features into a wider portion of the network itself, and working globally with other carriers on the development of the new technologies necessary for the proper implementation of these projects. In light of the revolutionary changes taking place in international society today, the provision of end-to-end services is vital to ensuring communications in the truest sense of the word. We look forward to facing these continuing challenges.

The Keys to Success: Teleglobe Canada's Successful Transition from Government Carrier to Private Sector Telecommunications Concern

---

Abstract

Since privatization in 1987, Teleglobe has emerged as a world-class information technology and telecommunications corporation. The keys to success have proven to be very similar at both the micro and macro levels of our organization: interpersonal, interdepartmental, intercorporate and international. Modeled on the dynamic transformation since privatization of our previously engineering-oriented corporate culture, this presentation outlines the revolutionary post-privatization changes at Teleglobe that have poised us for success in the international marketplace.

Four years after its privatization, Teleglobe Canada is well on its way in the transition from a government-owned crown corporation to a private competitive business enterprise. During this rather complex process we put a great deal of thought into the potential for our corporation — and we realized that we had the capacity to be much more than the telecommunications carrier we were a number of years ago.

Today, our clear, responsive, customer-oriented vision has led us to become a world-class, billion dollar, international communications and information technology corporation. As I will reveal through this analysis, modeled on the four-year evolution of our corporate culture — a previously technologically-oriented and engineering based culture — the

DEC 27 '91 11:36 FROM TELEGLOBE COMM. PAGE.002

pattern for our corporate success in the international communications marketplace has become clear.

At the time of privatization, in 1987, Teleglobe Canada's raison d'etre was the maintenance and growth of the *international network.* Our mandate was to provide technical excellence and high-quality expansion — to provide the installations and facilities required to operate an efficient international telecommunications network. This technological approach has been described as the "*gold-plated approach*": providing long-term, highly complex solutions, that — although impressive and technically first-rate — were often costly, generally developed in isolation, and (due to a frequently protracted development and implementation framework) often no longer responsive to the rapidly-changing demands of the marketplace when they were eventually introduced.

This was typical of what we recognize today as the carrier approach: focussed on technical excellence, steadfast perfection and response to the *corporate* network demands with expert know-how. We were also unregulated. But this meant that the scope of business activity of a government-owned entity was strictly limited to specific domains: the development of an international telecommunications infrastructure to serve Canadian needs; fulfillment of a number of governmental socioeconomic objectives dictated by national policy considerations; and discharging a number of

DEC 27 '91 11:36 FROM TELEGLOBE COMM. PAGE.003

governmental obligations within international organizations including technical assistance and multi-lateral developmental activities.

Privatization and regulation brought significant and immediate change to Teleglobe. Issues such as *return on equity* and *rate reduction* compelled us to scrutinize our performance and productivity standards. In response, we reduced our rates by almost 40% in four years. We negotiated a tarif scheme with our national and international partners that allowed us to be competitive in a global context and — given Canada's geographical situation— particularly vis à vis our American counterparts. The changeover to a private company culture also lead to the development of the successful customer-oriented vision that Teleglobe has today. Satisfying customer demands is indeed, in our view, the optimum measure of business success.

Privatization redirected the focus of our corporation outward. In the late 1980's, terms like *partnership*, *customer*, *competitiveness*, *business solution*, *flexibility* and *opportunity* began to gain a foothold in the Teleglobe Canada vernacular. Among the many initial organizational changes reflecting this new focus, the Engineering & System Development Department was renamed the Network Development Group and was given the new mandate to examine the goals of network development from the perspective of the customer, and the services that would satisfy their requirements in terms of

DEC 27 '91 11:37 FROM TELEGLOBE COMM. PAGE.004

quality, diversity and cost. *Whose needs were we answering?* Could we provide quick, high-quality solutions that reduced overall communications costs for our customers; that responded quickly and affordably to their needs; and that made Teleglobe a more successful enterprise? The clear answer was "*yes*".

From this simple, yet important, realization — the keys to success came within our grasp. Drawing upon the marketing-driven, entrepreneurial spirit of our new parent corporation, Teleglobe began the process of positioning itself as the competitive, customer-focussed, world-class corporation we have become today. The new Teleglobe represents a family of international business units that, together offer products, systems, services and end-to-end support to help our customers communicate with their world.

Our Communication Services unit, which includes Teleglobe Canada — and our Marine, International, and Information Management companies — provides international communications, consulting, data processing and marine services to a broad business and consumer base throughout the world. The Communication Products unit designs, manufactures and markets products and systems that link a wide range of systems with integrated data network solutions. Our Insurance Systems unit provides software solutions to the general insurance industry. With our newly-formed Research and Consulting units, we are creating a competitive synergistic

PAGE.005

DEC 27 '91 11:37 FROM TELEGLOBE COMM.

whole in the world market for voice, data transmission, private networks and systems integration.

Another key to recognizing our potential was the realization that we were *unique*. Teleglobe has a wealth of technical expertise, long-standing presence in international telecommunications consortiums and alliances, and a North American-based, highly-digitized, international network of cables and satellites that connects Canadians with over 220 countries — yet with only 2,500 employees worldwide we are not encumbered with the bureaucracy that often impedes rapid response and change.

With that in mind, we've introduced more new services in the past *four* years than in the previous *forty*. From virtual private networking — to *Globedirect's*™ direct interconnection, the range of services has multiplied to keep pace with the demand from our growing roster of clients. Teleglobe obtained the right to provide Canadian business customers with direct interconnection to the Teleglobe network — and in the process, saved them up to half of their international communications costs. We've doubled our sales force and introduced toll-free customer service numbers. Over half the Pacific transit traffic now passes through our state-of-the-art network. We've reduced our service implementation time by more than half. Teleglobe senior management and professional staff have gone out "on the road" and participated in four Client Listening Programs over the past year — and met with hundreds of

enthusiastic (*and rather surprised*!) customers. By listening to our customers in every way possible, we will ensure that our network and service development strategy continues to meet with their communications needs.

To ensure that we can continue to offer these services at competitive costs, we have further stepped up our bilateral negotiations with foreign carriers for substantial accounting rate reductions. On average, Teleglobe now offers Canadians some of the lowest rates in the world. And we will continue to respond to the changing needs of the Canadian consumer in the marketplace. We recognize and welcome the need to maintain a competitive telecommunications environment in Canada. One that means more jobs for Canadians, a more dynamic and innovative industry, and better and more affordable services for our customers.

Today's Teleglobe has a new strategic thrust — directed towards our customers, more than ever. We view our network as a platform to deliver services to these customers. We have complemented this technical infrastructure with a nation-wide (and international) service network of people and products. Corresponding changes in Teleglobe Canada's technical workforce have also reflected this customer oriented approach — to the point where there is no longer an engineering group that exists today as an entity unto itself. Project teams now respond to the needs of a variety of internal clients. The majority of our engineers have been redeployed to support the

DEC 27 '91 11:38 FROM TELEGLOBE COMM. PAGE.007

Sales, Marketing, and Operations functions. Interdisciplinary, cooperative workgroups in these three areas now work towards short-term, immediate response to the internal and external needs of Teleglobe and its customers. Solutions are developed quickly and their application is monitored and adjusted over time.

A most recent review of our internal structure has lead to the establishment of a *Strategic Development Group*. Teams of expert resources form Network Planning, Marketing Business Development, Government Relations, and International Affairs comprise this unit. Together, we are the strategic thinkers who will guide the long-term network expansion and business development strategy of Teleglobe Canada.

This group will drive the Research & Development that fuels our competitive service development activity and cost reduction drive. We support the corporation's Global Strategy to increase network service offerings and the capacity of our international network. We have also formed a new Research corporation and made a multi-million dollar, long-term commitment to consolidate all staff engaged in R&D activities. The new Research Center will focus mainly on evaluating technologies and standards with a view to developing new services and methods of cost reduction through the introduction of *new* technologies. At every level of the corporation (from interpersonal to international) we have rethought our structure

DEC 27 '91 11:39 FROM TELEGLOBE COMM. PAGE.008

and function along the lines of responding to clients and providing high-quality services — quickly.

We are increasing our overseas presence to get closer to our foreign customers and have recently opened offices in the UK and Singapore, with more in store for the future. We recognize that our customers require network flexibility and affordability, *end-to-end*. Our response is to build a Canadian infrastructure to better serve our customers and their needs. Our recent alliance with IBM Canada to increase our points of presence in cities across Canada and better serve our national business customers exemplifies this. It allows more Teleglobe customers to benefit from cost-effective, direct connection to our Network through our *Globedirect*™ family of services. From the overwhelming response we've received to this service introduction, this is what our *customers want*.

Teleglobe's mission statement sums up our strategy succinctly:

> Guided by efficiency, innovation and dedication to customer satisfaction, our mission is to be the world's leading provider of global telecommunications and information management solutions, while creating the value that allows our customers, partners, shareholders and employees to share in our future.

While the shift in Teleglobe's corporate culture has been significant over the past four years — change has become, and

DEC 27 '91 11:40 FROM TELEGLOBE COMM. PAGE.009

will continue to be, an integral part of our corporation's identity as we adapt successfully to the evolving needs of the competitive marketplace. The guiding question remains the same: *"Whose needs are we answering?"* We are proud to say that more and more often we respond to that question with: *"We are answering the needs of Teleglobe customers, partners, shareholders and employees"* — and we know we've found the keys to success.

Comments on the draft of this paper by Dr. Tom Mandeville, are acknowledged with thanks.

Abstract

The rapid globalization of the information economy has emphasized new pressures for increasing the tradability of information services. Although the attributes of services and goods are clearly different there is no compelling case that the free trade paradigm and Heckscher-Ohlin pattern and direction of trade in goods is inapplicable to trade in services. On the contrary the principle of comparative advantage appears to be equally valid for services as for goods. Despite the absence of a theoretical rationale the advanced information economies have initiated GATT negotiations to establish a GATT type framework to regulate free trade in services such as telecommunications. There have been endorsed by self interest and apprehensions that non-tariff actions by developing economies might jeopardize the burgeoning free trade in services. Some countries have invoked the unconditional strategic trade theorem to protect high-tech sectors such as telecommunications under protection. But arguably the costs of rent seeking activities under such policies may be outweighed any benefits. Therefore, the normative prescriptions of the free trade paradigm still appear to be the best guide for policy formulation and institution building in international trade. The attempt to duplicate a GATT type regime for services is questionable when it is rudimentary because the advanced countries have subverted some of its cardinal principles. The rising sub-nationalistic hues at the core of the GATT free trade principles and has created a trilateral trading and telecommunications world. The theory of customs union postulates that regional trading blocs are second best. Regional trading blocs can be welfare raising if the major trading blocs opt for protectionist strategies and can be welfare enhancing if they pursue free trade strategies in telecommunications. The developing countries of the Pacific can reap vast benefits from modern telecommunications technology and there is no reason why that they will get further marginalized. However, the global welfare of free trade in telecommunications can only be realized if the policy makers in developed and developing economies can match their empty rhetoric on free trade to consistent policy actions. The GATT quest of free trade must pervade free trade in goods before it is duplicated to regulate trade in services such as telecommunications.

Keywords: Information economy. Negotiating free trade in Services. Telecommunications. Protectionism. Regional trading blocs. Asia-Pacific region. General Equilibrium Analysis.

1 Introduction – the globalisation of the information economy and the increasing tradability of services.

Most leading economies of the world are now information economies, where information related activities or the information sector generates the lion's share of national income and employment. The growing international trade in services is an indicator of the rapidity of the globalisation of the information economy. Developing economies are also rapidly restructuring, on occasion telescoping or leapfrogging the stagewise graduation process to become information economies (Juxxawalla et al., 1988).

At the epicentre of the globalisation of the information economy and the informatisation of national economies lies the revolutionary changes in information technologies. A cluster of microelectronic and optoelectronic technologies have profoundly changed the production, servicing and transmission processes that govern modern economic activity. The speed of electronically transmitted services have increased whilst the transactions costs have dropped dramatically. These developments have made services that were hitherto nontradeable into tradeable. The transnationalisation of production by multinationals corporations have stimulated the growth and diversification of trade in telecommunications services. The growth in intraindustry trade or trade in similar rather than different types of products is one indicator of the transnationalisation process. This in turn has contributed to the deregulation of the domestic and international telecommunication organisations. The domestic telecommunication monopolies had to abandon the natural monopolies based on the provision of universal basic telecommunications. Whilst international cartels such as the International Telecommunications Union (ITU) that monopolised international linkage and operation had to cope with increased competition. The ITU which had regarded telecommunications services as a nontradeable eventually abandoned its stance and complemented the General Agreement on Tariff and Trade(GATT) efforts to liberalise trade in services such as telecommunications. The globalisation of the information economy arguably is one of the important factors that made trade in services a central issue at the stalled multilateral trade negotiations (MTN) or the Uruguay Round (1986). The advanced information economies motivated by self interest established a parallel forum known as the Group of Negotiations on Services (GNS) to examine the feasibility of replicating a GATT type of regime to regulate the free trade in services such as telecommunications.

Trade in services occur when a resident or factor of one country receives a payment from a foreign counterpart. Trade in services covers both factor and nonfactor exchange of services. However, GATT since inception had steered clear of issues related to investment and factor movements. Under the aegis of the advanced information economies the GNS wanted to focus its attention on nonfactor services such as advertising, banking, financial, insurance, telecommunications, etcetera. However, developing countries that had a comparative advantage in labour intensive services such as construction wanted it on the GNS agenda. Curious anomalies surfaced when it came to the classification of services. For example, movement of personnel from advanced to developing is classified as services whilst the reverse process is defined as immigration (Nayyar, 1988: 40). The GNS agenda eventually included several new issues such as trade related investment measures (TRIMs) and trade related intellectual property rights (TRIPs). Many developing economies contended that the inclusion of new issues would distract GATT from making headway in the unfinished area of non tariff barriers reduction. However, proponents of GNS from advanced information economies eventually prevailed. It was argued that if GATT did not

address these new issues it would be forgotten in the dust of history (McCulloch, 1990: 334). In the GNS negotiations the telecommunications sector became a prime target of scrutiny and it was the first sector to be tested. The inordinate attention bestowed on the telecommunications sector at the GNS was undoubtedly due to the fact that it is one of the leading sectors of the emergent information economy. In fact, telecommunications is regarded as the electronic highway of the modern information economy (Robinson, et al., 1988).

The focus of this paper is on the issue of liberalising trade in services in the context of specifically freeing up trade in telecommunications. The analysis of trade in telecommunications services highlights the large gap that exists between the rhetoric of the advocates of free trade in services and their protectionist practices. The paper is organised as follows: Section 2 examines whether there is a theoretical basis for duplicating a GATT like regime specifically to regulate services such as telecommunications. Section 3 highlights that despite the free trade rhetoric on services at international fora, leading proponents resort to mercantilist domestic policies when self interest is at stake. Section 4 reviews the tenets of strategic trade theories which attempts to lend an air of respectability to protectionist policies for high-tech sectors such as telecommunications in developing economies. Section 5, examines the emergence of regional trading and telecommunication blocs from the perspective of customs union theory. The increasing competition between the blocs and their welfare effects are reviewed. Section 6 focuses briefly on the predicament of the developing Pacific nations. They could either benefit or get further marginalised by the development of telecommunications. Section 7 attempts to modify estimates of general equilibrium welfare effects consequent upon major regional blocs opting for free trade or protectionist strategies for trade in services. Finally, section 8 presents some concluding comments.

2. The theoretical rationale for a separate regime for trade in services.

Goods and services have different attributes. However, that by itself does not provide a justification for establishing a separate framework to regulate the free trade in services. In this section issues relating to characteristics of services and whether neo-classical trade theory and the principle of comparative advantage is tenable for trade in services just as it is for goods will be reviewed. The different attributes between goods and services were noted as intangibility, nonstorability or nonstockability, inapporopriability, nontransparency (Hill, 1977). Furthermore, it was noted that both the consumer and producer must interact for the rendering a service. The distinction between goods and services, however, remains fuzzy under the impact of modern technology. For example, the services of a tenor such as Pavarotti is converted into good when it is recorded on a compact disc or cassette (Bhgawati, 1984). Furthermore, services through telecommunications can be recorded and retrieved. Non-marketed intrafirm services with specialisation become marketed. Therefore, given that goods and services change character and can be splintered or disembodied from one another any regulatory system that attempts to separate trade in goods and services would be unnecessarily buying into a maze of definitional problems.

Based on the Ricardian notion that factor mobility is a prerequisite to render services recent taxonomies (Stern and Hokeman, 1988; Sampson and Snape, 1985) identify at least four broad types of services :(i)Both producer and consumer are immobile when the

service is transmitted (e.g. architects drawings to an engineer abroad). (ii) Only producer is mobile and has to render services at a location where consumer is immobile (e.g. Korean construction firm moving to build in Saudi Arabia). (iii) Only the consumer is mobile and has to go to the producers' location to consume the service (Japanese tourist visiting Hawaii to enjoy the pleasures of a tropical island). (iv) Both producer and consumer are footloose and can trade in services in any nominated location. The principle of comparative advantage is deemed to be tenable for the various types except, perhaps for type (iii) service where exporting factors can shrink the production possibility curve of the exporting country and shift it out in the importing country undermining comparative advantage. This happens because the autarkic price of the factor for the exporting country exceeds that of the importing country (Deardoff, 1985:53–68). However, even when the principle of comparative advantage is violated trading is positive sum game that enhances the welfare of the participants (Jones, 1985). The whole gamut of neo–classical factor endowments theory or the Heckscher–Ohlin model seems to be applicable with equal vigour to trade in services as it is for trade in goods (Hindley and Smith, 1984). The fundamental theorems such as the Samuelson factor price equalisation theorem also seems to be tenable in the case of services (Bhagwati, 1984). Trade theory does not provide a persuasive rationale to treat trade in services any differently from trade in goods despite the fact they have different attributes.

The classification of services has also been made on the basis of the cost of interaction between consumer and producer of service, defined as the simultaneity factor (Hirsch, 1989). The simultaneity factor assumes values near the upper limit of unity for services that require high interaction costs of the consumer with the producer, whilst for traded goods the simultaneity factor may be near the lower limit zero as the required interaction is negligible. The revolution of information technology has reduced the transactions costs and increased the interaction between service producers and consumers internationally. In other words it has increased the tradability of services.

The revolution in information technology has increased the tradability of services through telecommunications. Rent seeking developing economies are poised to milk some of these rents by instituting mercantilist polices. The advanced information economies and their multinational corporations do not wish to witness the undermining of the free trade in services. Although there is no persuasive theoretical basis for establishing a separate GATT like regulatory framework for services the advanced countries have flexed their muscle and put the issue of service negotiations firmly on the GATT agenda. However, without making the GATT regime on goods function true to its free trade charter the duplication of another flawed institution to cover free trade in services appears to be questionable.

3. Free trade in rhetoric but protectionist in policy actions.

The neo–classical free trade paradigm provides a clear message that free international trade based on perfectly competitive markets maximises national income of the participants and thereby global welfare. Free trade is the first best optimum and its spirit is enshrined in the GATT principles and upheld by all its members at least in their public pronouncements, although not in their policies. This may be due to the fact that although the powerful normative superiority of free trade may win the arguments on international

1255

trade it may not win the votes at home (Yeager and Tuerk, 1976). The lengthy deliberations on telecommunications in GNS is a case in point on the schizophrenic behaviour of both advanced and developing economies. They are overtly free trade in their rhetoric in international fora but are covertly protectionist when their self interest or rent earnings are threatened.

The lengthy GNS deliberations on telecommunications did not advance beyond the acceptance of the same principles of free trade enshrined in the GATT charter on goods. Basically, GATT principles are committed to free trade in a competitive market environment and therefore aims at removal of trade barriers that distort gains from trade (Feketekuty, 1988). A review of the principles agreed for free trade in the telecommunications sector show that they are the same old GATT principles with a new GNS label and they are: (i) Non-discrimination or the Most-Favoured-Nation (MFN) principle whereby all trading partners are accorded the same treatment. (ii) Transparency or making the customs duties and non tariff barriers to trade clear to prospective competitors.(iii) Equal treatment whereby foreign and domestic firms are treated equally by host governments. (iv). Developing countries were also afforded progressive liberalisation or market access commensurate with their level of development thereby affording them non reciprocity. (v) The rights of establishment or enabling the foreign firms to perform their business operations through local branch offices in the host country.

However, when the first principle relating to non-discrimination or MFN provisions was put into practice the most vocal advocates of liberalisation of telecommunications have sought to undermine it. The USA and its national lobbies such as AT&T successfully sought to exempt basic telecommunications from free trade coverage on the grounds that it would enable foreign competitors to free ride without offering any reciprocal benefits. However, when it comes to non-basic or value added services the USA and its giant telecommunications multinationals have enthusiastically supported liberalisation. Ironically these multinationals enjoy a decisive technological lead and are poised to free ride in the telecommunication sectors of other countries and make massive profits. The double standards applied to liberalising non-basic services whilst protecting basic telecommunications services exemplifies once again the truth in the allegation that 'free trade when you are strong and mercantilism when you are weak' has been the hall mark of the recent GATT negotiations on telecommunications services. Despite, the free trade rhetoric on services similar mercantilist behaviour was evident in relation to other sectors. For example, USA was reluctant to liberalise trade in aviation and shipping, caving into pressure from domestic lobbies.

The developing economies have also sought to undermine the demands for free network access or market access to domestic telecommunications market by unbundling the mode of delivery from the network access issue. They hope, thereby to secure a bargaining chip in subsequent rounds of GNS negotiations. Furthermore, developing countries, based on promptings of the ITU, would like to tradeoff market access for infrastructure development in the vital telecommunications sector. The apprehensions of developing countries on the open door policy to telecommunications trade is not without some justification. First, developing economies fear that a free market in telecommunications services and equipment will toll the death knell of their nascent domestic telecommunications sector. Second, they contend that technological and cultural

1256

imperialism and further marginalisation of their telecommunications sector would result because of predatory competition by foreign multinationals. Third, they fear the loss of economic control over vital strategic sectors such as telecommunications, banking and finance, shipping and aviation. They consider that such erosion of control over key service sectors will pose a threat to their national security and sovereignty. However, developing economies despite their defiant and protectionist posturing have often toed the line when threatened with trade sanctions and other retaliatory measures by the advanced countries.

A major stumbling block in the progress of GNS at the beginning was the stubborn stance taken by the International Telecommunications Union (ITU) which regarded telecommunications to be a nontradeable service. Partly, this was a legacy of the ITU as the supranational cartel that regulated the international trade in telecommunications during the moribund industrial era by its monopoly over technical standard setting, tarrification, accounting. The ITU cartel operation enabled the reaping of monopoly profits from the provision of vital services that ensured the international interconnectivity and interoperability of domestic telecommunications monopolies. However, multinational corporations in their push for internationalisation of production demanded independent network access for enhanced service. Telecommunications was crucial to a multinational firms efficient performance in the competitive international trade arena. The ITU was exposed as a rent seeking cartel which manipulated tariffs and accounting. It was also alleged that it failed to deliver as the official custodian of infrastructure development in developing countries. Under pressure and virtual blackmail the ITU has softened its uncompromising stance to become a partner with GATT. It now acts to complement and support the GATT negotiations to establish a free trade regime for services (ITU, 1991).

The progress on multilateral lateral trade negotiations at the Uruguay Round (1986) has been mainly thwarted by the intransigence of the advanced countries to reduce agricultural subsidies. With respect to GNS there is disarray and " the developed rather than the developing economies– which always espouse trade liberalisation but are sometimes driven more by mercantilist and protectionist impulses" (Woodrow,1991:341) are responsible for it. This is because their free trade rhetoric does not translate into policy actions.

4. The case of promoting telecommunications as a strategic trade sector.

The protectionist arguments for government intervention in high–tech sectors such as the tradeable telecommunications services has recently received some academic respectability from the so called new trade theories. The new trade theories incorporate market imperfections, such as economies of scale, product differentiation, game theory, and organisational strategies. These new theories purport to explain why strategic sectors can maximise national welfare if promoted by government intervention by granting tariff and non tariff protection. The new theories have explained the empirical puzzle why much of the world's trade amongst advanced countries is increasingly intra–industry or in similar goods and services rather than in dissimilar ones as explained by the neo–classical theory of comparative advantage. Return to scale internal to the firm and product differentiation become crucial in explaining the genesis of intra–industry trade. Here, the type of firm is invariably a multinational corporation and telecommunications play a vital role in both internal and international management of the firms production and trading operations.

1207

Many government's therefore identify high-tech production and service sectors such as telecommunications as winners on strategic grounds for special protectionist treatment. It is generally argued that they generate positive externalities and R&D on them will not occur at the required level because of inappropriability problems (Hindley and Smith,1984). These are grounds that new theories invoke to justify protection for high-tech sectors such as telecommunications (Grossman and Shapiro,1985).

It is possible to use game theoretic pay-off matrices to demonstrate that government's can shift rents and make the domestic telecommunications sector gain at the expense of potential foreign rivals (Brander and Spencer, 1981). However, in practice such interventionist policies opens up a Pandora's box of uncertainties. First, the various game theoretic outcomes from the behaviour of rival interactions are very difficult to quantify. Therefore, policy formulation to implement strategic trade theory becomes a formidable task and a risky business (Grossman and Richardson, 1985). Second, even when strategic trade policies are implemented they could attract foreign telecommunications firms to domestic markets. Then the government would be unwittingly subsidising the foreign competitor rather than the local firm, thus undermining the whole rationale of rent shifting (Dixit, 1984; Hortsmann and Makusen, 1986). Thirdly, the general equilibrium arguments militates against the strategic promotion of telecommunications sector as this would shift resources away from other domestic sectors. Cost rises would make other competitive sectors in the economy uncompetitive. The losses from adverse effects on other sectors may far outweigh the benefits from the promoted domestic sector thereby resulting in a large overall macroeconomic loss of welfare. Fourthly, the introduction of domestic distortions to generate national welfare benefits welfare at the expense of world welfare are beggar thy neighbour type policies that can lead to retaliatory actions. These deficiencies make strategic trade polices loose some their appeal.

Some analysts contend that there is nothing new about strategic trade arguments. They are allegedly the old wine of the infant industry argument in a new bottle. The infant industry argument has an economic basis if according to the Mill-Bastable theorem, the net discounted value of an interventionist action turns out to be positive. However, the finely researched findings of the political economy of protection militates against giving of protection even on a temporary basis as it has a tendency to outlive its usefulness. The political economy of protection highlights the inefficiencies associated with rent seeking behaviour (Krueger, 1977) and directly unproductive activities of protectionist lobbies (Bhagwati,1982). In retrospect even the architects of strategic trade theory acknowledge the allocative inefficiencies, administrative costs, and the dangers of retaliation by rivals and recant their support for strategic intervention (Krugman,1987). Therefore, after careful analysis of the inefficiencies inherent in strategic trade theory we concur that free trade is not passe after all (Bhagawati, 1989). It remains the dominant paradigm for distilling policy guidelines for international trade in telecommunications and other services.

5. The emergence of trilateral regional trade and telecommunications blocs.

The violation of the basic tenets of the free trade principles enshrined in GATT articles of non-discrimination or MFN clause, and tariff only restrictions are evident in the USA Super 301 laws, the voluntary export restraints (VER) on textile, car and other imports. One of the most flagrant violation of GATT principles is the French non tariff barriers on

1256

Japanese video cassette recorders (VCRs) known as the Poitier's syndrome. The French reduced Japanese VCR imports to a trickle by subjecting them to delaying customs checks in a remote border post called Poitier. The rising tide of neoprotectionism has led to the emergence of a trilateral trading world centred around North America, Europe and by default the Asia-Pacific Region. The close symbiotic relation that exists between trade and telecommunications has been analysed empirically (Karunaratne, 1988). It is manifest, in the configuration of telecommunications to three separate blocs corresponding to the three trade blocs: North American Free Trade Area (NAFTA), Single European Common Market (SECM) and the residual Asia-Pacific Trading Area (APTA). The leading information economies in the telecommunications blocs are engaged in fierce competition to become switching nodes for leased lines or regional hubs. England is the current hub for Europe and Hong Kong is the hub for Asia-Pacific region. But, Ireland in Europe, Singapore and Australia in the Asia-Pacific region are increasingly competing to becoming regional hubs (Langdale, 1988).

The theory of economic integration or customs union theory enunciated by Viner (1950) and refined by Lipsey and Lancaster (1957) clarifies that formation of regional trading or telecommunications blocs are a special case of the theory of the second best. This implies that regional blocs whilst they liberalise trade between partners in the bloc may be welfare enhancing only if the trade creation effects exceed the trade diversion effects. Vinerian theory defines trade creation as the increase in welfare due to extra consumption arising from cheaper imports from a bloc partner. Whilst trade diversion is the welfare loss due to higher cost imports from a partner. The fact that regional blocs can be welfare reducing make them second best as a move towards freer trade is not necessarily Pareto optimal. There is no reason why the logic of Vinerian integration theory is not applicable to trade in telecommunication services. In fact, the formation of NAFTA and SECM are expected to result in massive welfare increases because trade in services are anticipated to increase within the regional trading blocs (Globerman and Booth, 1989; Stehmann,1991). Much of the increase in intra-regional trade is anticipated to be generated from the expansion of value-added network services or VANS. However, the welfare improvements in regional trading and telecommunications blocs are at the expense of the rest of the world as they have beggar-thy-neighbour effects. Some features of the North American and European regional telecommunications blocs are reviewed next.

The NAFTA or Free Trade between USA and Canada has witnessed a significant liberalising of telecommunications trade between the two countries. The achievements of NAFTA on regional telecommunications provides a way out of the tardy global liberalisation efforts of telecommunications under GNS. However, the theory of customs union warns that regional liberalisation in telecommunications trade could be second best. Also from a global perspective it is welfare reducing because it is at the expense of the other telecommunication blocs. Nevertheless, significant breakthroughs on transborder US-Canada telecommunications trade have been achieved under NAFTA:(i) The right of establishment to compete in the area of non basic value added network services;(ii) the reduction of tariffs; the relaxing of non-tariff barriers or requirements on technical standards; (iii) improved transparency in regulation of telecommunications trade; (iv) streamlined bilateral dispute settlement mechanisms; (v) elimination of restrictions on direct investment and lifting impediments to the movement of business personnel. The NAFTA agreement dodged the thorny transportation and culturally sensitive trade issues.

The proposed Single European Common Market (SECM) in 1992 would integrate telecommunications networks and aid free transborder flows of telecommunications in the Common Market. The architects of SECM realise that telecommunications is not merely a service but a vital resource that can be harnessed for economic integration by facilitating macroeconomic coordination and microeconomic harmonisation. Telecommunications services plays a critical role like a single currency unit, free factor mobility, in integrating and making SECM a reality. Therefore, the Commission for European Communities (CEC) has invoked the competitive provisions of the Treaty of Rome, article 90, to end or vary domestic monopolies on terminal equipment , government procurement and technical specifications on services. The net trade creation effects emanating from an integrated telecommunications market among members of a community closely bound by economic and cultural ties are anticipated to be spectacular in the near future. However, the contemporary environment in Europe remains fractured by competition and regulation (Mansell et al.,1989:64) but there are inexorable political forces that will hasten the integration of European telecommunication markets in the long run.

6. The Asia Pacific Region & the developing Pacific Island Nations (PINs)

The increasing competition amongst partners in each regional telecommunications bloc is manifest in the arena of fibre optic and satellite facilities construction. In the Asia–Pacific Region the submarine coaxial networks are being duplicated by new fibre optic cables linking up the other regional blocs. Furthermore, Cable and Wireless in implementing their strategy of establishing a global digital network is linking up the ASEAN countries, Pacific Island Nations (PINs) and the other regional blocs and investing in manner that will deter rivals as foreshadowed in strategic trade theory. Also several new satellites are anticipated to compete with INTELSAT. The net result is anticipated to be massive excess capacity and fall in prices particularly in the Asia–Pacific Region. However, even in the Asia–Pacific region the major beneficiaries from the telecommunications development bonanza are likely to be the richer countries that include the four dragons (Singapore, Taiwan, South Korea and Hong Kong). Australia and New Zealand have already embarked on a closer economic relationship agreement (CER) and there are larger benefits possible from integrating into a single market (Lloyd, 1991).

However, the PINs scattered over 29 million square kilometres of the Pacific Ocean could miss out from the benefits of competition in telecommunications in the Asia–Pacific region. The dispersed nature make them suitable for footprinting by satellites. However, the PINs are on the thin route telecommunication locus and do not offer multinationals the prospect of cream skimming. The economic disparities that exist between PINs is reflected in the teledensity disparities (telephones per 100 population) which is 1.5 for Papua New Guinea compared to 67 for New Zealand. The rural urban disparities within PINs are also large (Jussawalla and Ogden, 1989). The double dualism that prevails in developing PINs has been censured on humanitarian and common interest grounds (Maitland, 1985). The radical perspective contends that infusion of high–tech such as telecommunications can further marginalise PINs economically and culturally. On the positive side, theoretical analyses shows that the integration of PINs into a regional bloc would improve their welfare due to the presence of multinationals and their job creation effects (Beladi and Samanta,1991).

7. Welfare scenarios for services due to pursuit of free trade versus protectionist strategies.

The emergence of a trilateral regional trading and telecommunications blocs are certainly second best as they do not maximise world welfare and further one region's gain could be at the expense of another bloc. However, in the area of trade in services all the trading and telecommunications blocs are poised to grow in a symbiotic fashion with the rapid globalisation of the information economy. Below, we make use of the estimate of the CIE (1990) computer general equilibrium (CGE) model calculations to map out the welfare scenarios due to the pursuit of different strategies by the major regional blocs. The estimates are only ball park figures for services based on the heroic assumption that trade in services comprise 30% of the value of total merchandise trade, as reported in GATT statistics. The welfare implications **per se** for telecommunications services cannot be estimated as published data on electronic trade in information services is not available.

The Pay-off Matrix for welfare effects of trade in services (Table 1) is estimated on the basis of a protectionist strategy and free trade strategy for North American region and the European region. The GDP changes due to the pursuit of the alternative strategies on other regions are quantified in the pay-off matrix. If both North America and European regional blocs on a protectionist strategy we have in cell I the estimates for the worse case scenario with global trade in services shrinking and decreasing world GDP by $US61 billion. Europe would be the worst affected, Asia-Pacific would account for an 8% share of the global reduction in GDP. If Europe opts for a free trade strategy whilst North America keeps the trade shutters on services world welfare will increase by $US 40 billion and Asia-Pacific will benefit as much as other regional blocs as shown in cell II. If Europe opts for fortress strategy whilst North America goes free trade on services, welfare increase would be only $US 15 billion and the Asia-Pacific gains are as much as the North American welfare gains as indicated in cell III. The best welfare scenario eventuates when both North America and Europe goes free trade on services. The welfare effect on the world is shown in cell IV, by the increase of GDP of $US 119 billion. Europe is the largest beneficiary from the best case scenario, accounting for nearly 4 times the welfare gains of the Asia-Pacific region. The difference in welfare gains from pursuing extreme worse case or protectionist and the best case or free trade strategies for services by the major regional blocs is about $US 180 billion (i.e. cell IV minus cell I). Also other calculations indicate that if Asia-Pacific decides to unilaterally liberalise its trade in services it could gain $US 67 billion with Japan being the major beneficiary (Banks and Stoeckel,1990).

Table 1. **Payoff Matrix for Trade in Services Protectionist Vs. Free Trade Scenarios Percentage ($US billion)**

North American / European		Protectionist		Free Trade	
		Cell I		Cell II	
Protectionist	Europe	-61%	(-37)	32%	(13)
	Asia Pacific	-8%	(-5)	28%	(11)
	North America	-31%	(-19)	40%	(16)
	World	-100%	(-61)	100%	(40)
		Cell III		Cell IV	
Free Trade	Europe	74%	(11)	53%	(63)
	Asia-Pacific	13%	(7)	16%	(19)
	North America	13%	(7)	31%	(37)
	World	100%	(15)	100%	(119)

8. Concluding remarks.

The international trade paradigm and associated principles of comparative advantage appears to be equally applicable to both goods and services such as telecommunications, although they share different characteristics. Therefore, there is no theoretical grounds for asserting that policy making or institution building for regulating the free trade in services should be different from free trade in goods. Therefore, it is quite pertinent to question all the fuss about negotiating for a free trade regime for services (Voigt,1991).

The fact that the principal architects of GATT have flagrantly violated the cardinal free trade principles enshrined in Article 1 by non-tariff barriers needs to be rectified before a similar flawed system is duplicated for services. The replication of a malfunctioning systems does not augur well for free trade in services. It may only distract GATT from the task of counteracting the non-tariff barriers that is gnawing at its very existence as free trade custodian of the world. Non-tariff barriers on goods are so adverse in their welfare impact and opaque when instituted. But the insidious effects and nontransparency problems with regard to services are likely to be more complex and unless the practioners of neoprotecionism eschew them and act according to GATT free trade principles having a separate GATT like regime for services will not ensure free trade in services. Therefore, the fundamental problem that appears to threaten the world trade system is the spread of non-tariff barriers in goods and services or neo-protectionism. This has to be tackled head on by spokesman for both advanced information economies and developing economies by matching their public rhetoric on free trade with concrete policy action at home.

COMPETITION IN AUSTRALIA

A WINNER'S PERSPECTIVE

INTRODUCTION AND SUMMARY

On November 19th , 1991, a consortium named Optus Communications was announced as the winner of the competitive bid to purchase AUSSAT, Australia's domestic satellite carrier, together with a second carrier licence.
This paper describes the background to the unique bidding process, the regulatory environment adopted by the Australian Government and the strategies employed by Optus to present the winning bid. It further describes how, having won the licence, Optus intends to build and develop its network and services and rapidly provide the benefits of competition to the Australian public.

BACKGROUND

On November 12th 1990 the Minister for Transport and Communications, the Honourable Kim Beazley M.P. published a document entitled " Micro-Economic Reform: Progress Telecommunications". This document recorded the decisions made by the Government to introduce full network competition to Australia. The most significant steps in the process are as follows:

- the establishment by the end of 1991 of a private sector competitor to a merged Telecom/OTC in the provision of network facilities,
- the introduction as soon as practicable during 1991 of competition in the provision of services through introduction of full resale of domestic and international telecommunications capacity. In other words the current distinction between value added services and reserved services will be eliminated,
- three Public Mobile Telephone Services licences will be issued, including one to AUSSAT prior to its sale and one to Telecom/OTC. Telecom's MobileNet will be required to sell air-time on its existing analogue system to other PMTS licencees,
- the provision of Public Access Cordless Telephone Services (PACTS) will be opened to full competition in accordance with the recent AUSTEL recommendations,
- the issue of further mobile PMTS licences will be considered in 1995, and
- the duopoly will be reviewed on 30th June 1997.

The mechanisms adopted to achieve this process were revolutionary and wide ranging. It is clear that the Government had learned from the competitive experiences in the USA, UK and Japan. It was determined that where competition had been slow or incomplete, that the impediments causing those deficiencies would be removed. In achieving this, the Australian Government had the clear advantage of being the outright owner of the incumbent monopoly carriers, Telecom Australia and OTC.

The principal strategies proposed to encourage the rapid establishment of effective competition were as follows:

- Telecom would be required to provide interconnection for the second carrier on an equal access basis, **at directly attributable incremental cost.**
- Telecom would be required to share ducts, radio sites and other facilities where practicable,
- Telecom would be required to originate, carry and complete calls on behalf of the second carrier,
- Telecom would be required to provide full access to information about traffic carried on the network,
- International access will be equally available to both carriers

The regulatory body AUSTEL was charged with overseeing the detailed implementation of these arrangements. Its major functions were defined as: technical regulation; promotion of fair and efficient market conduct; protection of customers and industry policy objectives.

1257

David J. Lawrence

Optus Communications

The other major announcements in the paper were the proposed merger of Telecom Australia and OTC to form a single entity to be known as Australian Overseas Telecommunications Corporation (AOTC) and the arrangements for the sale of AUSSAT, Australia's domestic satellite carrier.

Overall, the paper set the stage for the most rapid and widespread introduction of competition in telecommunications ever attempted in an OECD country. A great deal of detailed work was needed to put these strategies into legislation and operation, but they have survived substantially intact and their effects will shortly be visible in the Australian telecommunications market.

FORMATION OF THE OPTUS CONSORTIUM

Within days of Minister Beazley publishing his paper, both BellSouth and Cable and Wireless were independently evaluating the opportunity. Cable and Wireless, as part of its global marketing strategy, maintained a small business office in Australia, while BellSouth had a significant interest, having acquired the largest paging company in Australia, Link Communications.

Both companies already had interests in the region. Cable and Wireless had been involved in bidding for Telecom New Zealand, which was sold in 1990 to a consortium of Bell Atlantic and Ameritech. BellSouth were preparing for cellular operations in New Zealand, in addition to their Australina operations.

Given the magnitude of the Australian opportunity, which encompassed domestic wireline communications, cellular and international, it made sense for the two companies to get together and letters of intent were exchanged in December 1990 between BellSouth and Cable and Wireless.

The Australian Government was prepared to wait, as was New Zealand, five years before requiring majority Australian ownership of the second carrier licensee. However, both BellSouth and Cable and Wireless believed that a consortium which was Australian owned from the outset would have a greater chance of success.

In March and April 1991, after much 'behind the scenes' negotiation and discussion a tentative consortium came together consisting initially of :

• BellSouth	24.5%
• Cable and Wireless	24.5%
• Mayne Nickless	20%
• AMP Society	10%
• NMP	10%
• AIDC	10%

The Australian partners have since formed a holding company, Optus Pty Ltd. which now owns 51% of Optus Communications.

BellSouth and Cable and Wireless as the 'telecommunications partners' were to be responsible for the building of the network and the initial marketing of services while the Australian partners provided valuable input in the areas of industrial relations, industry policy and of course lobbying.

DEFINING A STRATEGY

The first major task facing the telecommunications partners of the newly formed and 'yet to be formalised' consortium was the development of an overall strategy and an accompanying business case. On the major strategic assumptions, BellSouth and Cable and Wireless were remarkably close together from the outset.

The first and obvious priority was to develop a strategy which would win the licence and the right to purchase AUSSAT. To achieve this, it was obviously necessary to pay close attention to the Government's priorities, which as they stated in numerous publications were listed as:

- rapid development of network based competition and the offering of competing services to a broad spectrum of Australian consumers,
- development of an industry policy showing tangible benefits to Australian manufacturing and exports,

- Australian participation and the creation of new jobs.

The actual bid price for AUSSAT was consistently downplayed by the Government as being of relative unimportance. However, since it had been announced that AUSSAT would be sold debt free, which meant the Government picking up between A$700-$800 Million, there would clearly be political pressure to recover as much as possible from the sale of AUSSAT.

With these priorities in mind, the consortium agreed on the following major assumptions to be tested in the business case:

- that Optus would be a facilities based full service carrier and would make use of AOTC infrastructure only in the early stages of its development. Optus would not be a reseller in the long term.
- that Optus would not provide services until it could do so with its own billing systems as a minimum.
- that Optus would build its network as rapidly as technically feasible given the economic and geographical constraints imposed by the Australian market.
- that Optus would form strategic alliances with major equipment vendors to assist in developing an industry policy attractive to the Government and ensuring the rapid delivery of vital infrastructure after the licence award

Developing an agreed business case was a lengthy exercise, of which perhaps the most interesting and contentious issue was the prediction of market share.

In both the UK and the USA, the growth of market share by minority carriers had been relatively slow, impeded by interconnect regulations which had evolved rather than been imposed. In Japan, where competition had been introduced in international services with equal access, the growth of market share had been explosive.

Determining a realistic formula for market penetration in the Australian environment under the 'not quite equal' interim access conditions proposed, was a major undertaking. Too little share would result in a non-viable business case, too much would overwhelm a network in its embryonic stages of development. With little relevant experience world-wide, this problem remains the biggest unknown that Optus faces. However, when its initial network is built, the upper limits will be set for the short term.

(It is interesting to note that long after the Optus business case was developed, AUSSAT launched its own international telephone service across the Tasman Sea to New Zealand. Service commenced in July 1991, serving the Sydney market only. In December AUSSAT reported that it had gained approximately 15% of the available market using the alternate access code 0099 in place of the OTC code 0011.)

Technical decisions which were built into the business case were as follows:-

- Subscriber/Tandem switches would be installed in Canberra and the five major state capitals by the middle of 1993,
- Inter-city fibre optic links would be built using 2.5Gbit SDH technology to extend from Brisbane to Perth by 1997,
- Fibre optic rings would be built in the central business districts of the major state capitals and Canberra to enable direct connection and centrex services to major business customers,
- A GSM cellular network would be built to cover 80% of the population by 1997
- Intelsat earth stations would be built to enable access to both the IOR and POR satellites by the fourth quarter of 1992
- An international gateway switch would be installed in Sydney by the fourth quarter of 1992,
- To establish a customer base and early visibility for Optus, the air-time resale of Telecom's AMPS cellular service would commence in mid-1992,

- To commence the development of integrated operational support systems with the aim of, not only providing Optus with the ability to compete effectively, but of building a potentially valuable export product.

RESPONSE TO THE "REQUEST FOR PROPOSAL"

The Government had called for detailed proposals from those parties intending to bid for the purchase of AUSSAT to be submitted by July 15th. At the time, no official information was available on the number of interested parties. A reported total of 25 companies had filed an expression of interest, but it became increasingly clear that only two consortia were seriously pursuing the opportunity.

Optus made a decision to disclose its plans in considerable detail to the Government in its response and submitted a substantial document with heavy emphasis on its industry policy, supported by the strategic vendors which had been selected for its major infrastructure.

The proposals were treated in strict confidence so nothing is known of the relative merits of those submitted, but the outcome was that two consortia submitted proposals and two consortia were 'short listed': Optus and the Kalori consortium consisting of Bell Atlantic, Ameritech and Hutchison Telecom.

PLANNING AND CAMPAIGNING

The Government announced that it would be holding to its original timetable and that the short-listed contenders would be required to submit their final tenders for the purchase of AUSSAT by the end of October.

In the meantime, a two month period was allowed for the individual negotiation of a detailed interconnect agreement between both contenders and AOTC. The negotiations were intended to be bilateral, allowing for different agreements with each contender and were to be commercially based. Recognising the difficulties of interpreting the original Government offer of interconnect at 'directly attributable incremental cost' , Austel was charged with producing the initial charges for basic interconnect which are discussed in more detail in another section of this paper.

There were a number of important tasks to be accomplished in the period between submitting responses to the RFP and the final tender. Among these the most important were:

- The development of Optus' industry policy to the point where tangible and irrevocable commitments could be made.

- Monitoring and providing input to the new Telecommunications Act which had to be passed by the Commonwealth Government before the sale of AUSSAT could proceed.

- The negotiation of a draft licence.

- The negotiation of a sales contract acceptable to both Optus and the Government.

- The due diligence process, not only on AUSSAT which was being purchased, but in lesser detail on Telecom and OTC who held all the necessary information for sizing and valuing the existing market.

Optus established three teams for this period of the bidding process. A commercial team responsible for interconnect, and negotiations on the sale agreement and licence. A Public Relations team responsible for all lobbying and PR activities and the largest groupt of all tasked with Implementation Planning.

Because Optus had promised a rapid roll-out of its services and infrastructure in its RFP response, it was clear that the initial engineering, marketing and planning work could not wait for the award of a licence.

The implementation planning team therefore continued to work on developing detailed specifications, designs and marketing plans on the assumption that the licence would be awarded to Optus. There were obvioulsy additional benefits from this work in support of the commercial team and in the continual refining of the business case which would ultimately determine what Optus could afford to offer for AUSSAT.

1270

The result of this not inconsiderable effort was that , by the time the award was announced on November 19th, Optus had almost completely specified and agreed configurations and deliveries with major vendors, it had undertaken detailed studies of probable routes for its fibre optic links and was well advanced in the procurement of interim support systems and the planning of its GSM network configuration.

INTERCONNECT

In April 1991, Austel published progress and interim reports on the technical and operational framework and the arrangements and charges for interconnect. These were intended as discussion documents and generated widespread comment from Telecom, OTC and other interested industry participants including, of course, the then potential bidders for the second licence.

In June, Austel published confidentially its proposed usage charges for interconnection. The press release accompanying this determination referred to an average single ended charge in Metropolitan areas of A$3.14 cents per minute.

Given that untimed local calls in Australia cost A$0.24, allowing resellers an effective interconnect rate of about A$5.3 cents (based on a 4.5 minute call) payable only on effective calls, this determination is not particularly favourable to the second carrier. However it fell within the range of Optus' expectations.

The detailed interconnect arrangements negotiated with Telecom and OTC during September and October are still covered by confidentiality agreements and cannot be disclosed. Optus was able to draw upon the experience of Mercury in the UK, which, combined with well known precedents in the USA and Japan, made possible the negotiation of a satisfactory interconnect agreement in what must be a world record time.

For the benefit of those not familiar with the Australian interconnect environment the following are its major features:

- subscriber access from the AOTC network, prior to the implementation of full equal access, requires a single digit access code. For example instead of 03 nnn nnnn to dial Melbourne from Sydney, a subscriber choosing Optus will dial 103 nnn nnnn.
- Optus has the right to use capacity leased from AOTC to connect customers to its network, to connect Optus facilities to AOTC points of interconnect or to connect nodes on the Optus network.
- AOTC will supply CLI (calling line identification) to the Optus network when calls are handed over.
- AOTC will provide BNA (billing name and address) to Optus so that Optus may bill its customers directly from the CLI data.
- AOTC will prepare for equal access based on pre-selection and must be in a position to provide it on 100% of its customer lines by 1997. The method, and precise date of implementing equal access has not yet been determined.

Initially these arrangements are applicable only where AOTC has the technical capability of providing the necessary facilities. CLI is available at present only from about 69% of the Telecom network, but AOTC is committed to provide it on 100% of their exchange lines by 1997

THE OPPOSITION CRUMBLES

Having proudly announced the addition of France Telecom to its consortium in early October, a move that seemed to Optus necessary in view of its lack of international operating experience, Kalori announced later in the month that Bell Atlantic, Ameritech and France Telecom were pulling out, leaving Hutchison Telecom to continue alone.

This announcement, though preceded by the usual flood of rumours, came as a surprise to all concerned. Optus viewed the development with mixed feelings since, while it welcomed the 'downsizing' of its opposition, there seemed to be a real risk that, if all competition evaporated, the Government might be forced to rethink its entire plan.

In the event, Hutchison Telecom confirmed their intention to continue alone, with the addition of AT&T as a strategic vendor and presumably adviser and they left open the option for Telecom New Zealand to take equity in the consortium after a licence was awarded.

THE RESULT

Optus submitted its bid on November 12th. Given the length of the bidding process and the complex and detailed negotiations necessary, the final submission date was remarkably close to the Government's originally announced deadline.

By this time most media commentators were confidently predicting an Optus win and Optus confidence was high. However, Hutchison Telecom remained a serious contender with substantial resources and it was therefore with feelings of great relief that the press release was received from Minister Beazley's office on the afternoon of November 19th, announcing the award to Optus.

The reasons why Optus was selected will never be fully revealed, and perceptions are so often more important than facts, so perhaps some extracts from an article by one of Sydney's better informed journalists will have to suffice:

"If prizes are to be handed out for the most professional lobbying exercise of the year, Optus Communications would win hands down..."

"...a race Optus won in a trot, having burned its opposition with a very professional combination of lobbying, marketing and public relations backed by a solid and credible business case crafted to meet the concerns of the decision makers."

"The first and probably most significant advantage Optus had was...Link Communications, a paging company and subsidiary of...Bell South"

"Early on it announced the involvement of UK operator, Cable and Wireless. This had the double advantage of a partner, which through its subsidiary Mercury Communications in the UK knew what is was like to take on a monopolist (sic) carrier and which had experience running an international telecommunications network. Bell South and C&W together were enough to scare off most of the so-called 25 expressions of interest proving that if you look and act a winner you can often become the winner."

"One local partner, Mayne Nickless, gave the consortium a strong base in local industrial practices...Through Mayne, Optus managed to covert the communication's union from being a trenchant critic of competition, with threats only 12 months old of refusing to connect the second carrier into the Telecom network, into a positive supporter in Canberra. Not only a supporter but a critic of the opposition..."

"In contrast the opposition Kalori, decided to keep quiet, strangely arguing it was a commercial bid. In reality it was clear Kalori was a long way from having its bid in final form.

This reflected Kalori's biggest problem, a consortium group which had partners with very different ideas of how they were going to play it and who was really in charge."

Tom Burton, Sydney Morning Herald, December 14th 1991.

The award was, and is still, subject to final agreement on detailed financial arrangements and the actual closing of the sale of AUSSAT is now scheduled for January 31st 1992.

OPTUS DEVELOPMENT PLANS

The key elements of the Optus proposal to the Government were:

- Rapid Rollout
- Partnership with Suppliers
- Skills and Experience of Foreign Partners
- Australian Ownership
- Market Benefits

Of these, only the Rapid Rollout and Market Benefits remain to be demonstrated.

1272

Rapid Rollout

Market	Date
Cellular Resale	5/92
GSM Cellular	6/93
STD/ISD Coverage	
45%	12/92
70%	6/93
100%	12/96
Business Network Services	6/93

By the middle of 1993, Optus service offerings will include the following:

- Domestic and International Long Distance Service
  - Directly connected access
  -Indirect access
  -Operator Services
  -Calling Cards
  - Freephone Services
- Wireless Services
  - Resale of Analog Mobile Service
  - GSM Services
- Business Network Services
  - Centrex
  - Private Lines
  - Virtual Networks
  - Facilities Management
  - Consultancy and systems integration
  - ISDN
  - Video Conferencing
  - Facsimile Services
- Satellite Services
  - Transponder Leases
  - RCTS
  - VSAT Data Services

Partnerships with Suppliers

Optus strategic suppliers include the following companies, or their Australian subsidiaries

- Nortel
- Fujitsu
- NEC
- DEC
- Exicom
- Leighton Contractors
- Olex Cable
- Nokia

The fundamental relationship between Optus and its suppliers concerns training, Australian content in manufactured products and R&D commitments in Australia.

While most of these relationships are for the delivery of technology products in production, the development of Optus' OSS (Operational Support Systems) has attracted widespread interest and may well have had significant impact on its overall bid.

It is extremely rare for an major telecommunications company to attempt, or have the opportunity, to develop a complete suite of support systems from scratch without having to integrate or otherwise dispose of its existing systems. In most cases, carriers have developed systems to perform specific tasks at different times and it is rare for more than two or three of them to be able to communicate and share data.

Optus, with Digital Equipment Corporation, Australia as its prime contractor, systems integrator and potentially joint venture partner, intends to develop a totally new, fully integrated OSS. This development will not only provide Optus with the tools to compete effectively on service, but will also represent a potentially valuable saleable commodity.

In terms of available skills and development costs, Australia is an excellent location for the development of major software and the Optus OSS could become a significant source of export earnings.

Market Benefits

The general benefits to the consumer derived from competition in the provision of services need no repetition in this paper. Specifically Optus has predicted that the advent of competition will reduce the cost of long distance and international calling by 40% in real terms over the next five years and by 60% in the next ten years. It should be remembered that Australia already has some of the lowest prices in the world for long distance and international telephone service. Lower, for example, than the United States on a per minute/per mile comparison of most long distance tariffs.

A less tangible, but nonetheless important benefit, will be an improvement in standards of service which, according to many Australians, is a process that has noticeably started already.

SUMMARY

Around the world, more and more countries are experimenting with the introduction of competition in telecommunications. The completely laissez faire free market approach is being tried in New Zealand. Regulated competition from multiple service providers is changing the face of telecommunications in Japan

The Australian experiment is unique in that a regulated, limited term, duopoly has been created in an environment where competitive services can be delivered rapidly to the majority of the population. A major national and international carrier can be built from scratch, taking advantage of the latest technology without the burden of an existing obsolescent infrastructure. This is an opportunity which has been seen nowhere else in the world, but it could very well become a model for other countries to follow.

1274

TECHNOLOGY AND CHANGES IN VIDEO MEDIA

By Alan (Al) Levin
President - Professional Video Transmission Services (PVTS)
Washington, D.C., U.S.A.
Presented at The Pacific Telecommunications Conference
Honolulu, Hawaii, January 1992

ABSTRACT:

Rapidly evolving technology and a spirit of global access and deregulation will modivate "The Video Media Establishment" of today to continuously redefine itself.

New and old players alike who represent massive amounts of collective telecommunication bandwidth, will access "dynamic" and "seamless" digital highways. The term "video media" will broaden, to be thought of as "multi-media" toward and through the end of the decade.

Until about 10 years ago, a paper on technology and the video media would center on TV network broadcasters with deep pockets who freely used technology to enhance their product. These were "over-the-air broadcasters," not cable entities, and they accounted for over 91% of TV viewership in 1980. Today their share hovers at 60% and is dropping.

The economics of broadcasting was changed by technology and deregulation. The diffusion of audience share now motivates broadcasters and cable entities alike to use technology to reduce overhead in an attempt to maintain profit margins and competitive status.

The milestones that sowed the seeds of this diffusion of viewership were evident to only a few in the early '80s. In hindsight, a clear cause-effect pattern is evident.

1. International satellite communications that developed during the early and mid-'60s brought the Vietnam War into American homes. This had the effect of elevating TV news, as opposed to the print media, to the primary source of news for the American public.

   This was a boon for networks then but was also the technological seed for the proliferation of cable TV via satellite - an economically diffusing force for the networks now.

2. The development of ENG - electronic news gathering - that occurred in the early and mid-'70s. This technology involved small electronic cameras and their associated video tape and microwave units to replace film cameras in the field. The almost obligatory local "live shots" became the norm during the late '70s, further enhancing the prestige of the video media in the public eye.

3. SNG - satellite news gathering - made it practical for ad hoc coverage of major events by news cooperatives - allowing independent stations to cover national and international events as never before.

4. Both SNG - fly-away-transmission systems - and ENG camera technology brought the invasion of Panama and the Gulf War into homes more dramatically then ever before. SNG made "live shots" commonplace on a global scale.

   Deregulation along with new and diverse technologies, will continue to drive change in the global video media in the '90s.

   We see a continuation of a pattern where technology and deregulation first aids the media "establishment of the day" but through increased efficiency begets opportunities for a new and broader media "establishment of tomorrow." This was CNN's path.

Fifty to 100 or more cable or DBS channels are taken for granted by today's youth. In my youth, 3 channels were the norm, and my parents were more than satisfied with radio.

Thus just to hold its own, today's video media establishment must keep pace with technology and deregulation while maintaining its client base.

In this sense, video media must constantly "re-invent" and "redefine" itself into a changing environment for it to grow and prosper. If an entity cannot grow with rapid advances in technology and deregulation, its very survival will be threatened. Loyalty to an industry is admirable, entrenchment in a fixed technology can be fatal. Technology will always change.

Our company was founded about 11 years ago, primarily to provide non-editorial technical services to foreign broadcasters based in Washington, DC. We provide camera crews to collect news, videotape editing services, and studios. We added a 7-antenna teleport 2 years ago because of increased demand for transmission services.

We have had to avail ourselves of all the latest technologies to stay ahead of the crushing effect of technological advancement. We developed (in house) a fly-away video uplink system with a communications package so that we could properly serve our clients. By adding technical redundancy, the communications package, and 5 channels of program quality audio, we were able to stylize the uplink system to our particular client base.

In the case of our work with Wold International, we developed an advanced computer control system so Wold could route signals for its clients with maximum control and flexibility.

Over the years, we have seen our client base expand to include US-based networks and cable entities, corporations, governments, and educational institutions. The term "news" or "media" can still be loosely applied to the majority of our client base.

News is a relative term, be it local, national, or international and can pertain to a narrow industry or special interest group. For instance, we do a lot of work involving "VNRs" - video news releases. This usually relates to an industry or special interest group. We work directly with the White House to do point-to-point full motion, broadcast quality, teleconferencing. This allows the President to address larger groups, usually conventions, without the time and expense of travel. During the election year, we will be doing a lot of media campaign work. We call this EWC - Electronic Whistle-stop Campaigning - and this always makes news in one way or the other.

Increasingly we see that the term "news" is interchangeable with information and knowledge. Its exact focus can change from client to client. Raw news is edited and given whatever "spin" a client desires. That's their editorial call and is a direct extension of freedom of the press.

We provide a working platform with information or news pools that our diverse client base share. Thus, we are able to reduce cost through technology and pooling clients together informally when covering big news stories such as wars and political conventions.

If one equates news to information and knowledge, then the distribution of knowledge is the root and destiny of the continuing re-invention and redefinition of video media. This is our industry.

We look for the following:

1. The free flow of information will increasingly define economic and social vitality, analogous to the opening of trade routes in the 1700s and the interstate highway systems in the 1950s.

   Free flow with a minimum of regulation is the key here. Just as a highway that ends or becomes restricted by a national boundary is compromised in its value, so are telecommunications paths that are restricted by jingoistic policies or closed architecture.

2. Along with global deregulation, telecommunication technology must become "seamless," "dynamic," and "on demand."

   This implies that digital technology, with open-ended architecture, will dominate.

   a. "Seamless" - The bandwidth occupied by the digital path will, in most cases, be a mix of various fiber and satellite paths selected by complex optical computer switches. The user of such a system will be able to activate a "class" of services based on performance/economic criteria.

   b. "Dynamic" and "On-demand" - This is critical for economic, video, or high bid rate data service such as our client base uses.

"Broadcast quality" will probably imply compression with a minimum of 8 to 40 mbs when HDTV-criteria is considered. A broadcaster wishing to backhaul news or sports feeds to its hub must be able to dynamically create and expand a digital path on deregulated highways to compete economically. This is true NOW in today's world and is greatly needed.

Bandwidth on demand is not currently available for analog video. The 4 American TV networks each maintain 24-hour transponder paths over the Atlantic, costing each over a million dollars per year. Eighty to 90% of the time, test signals traffic these paths as news and sports feeds occur intermittently.

The only time I can remember that this arrangement made any economical sense was during the Gulf War when there was 'round-the-clock coverage. At times, these non-dynamic paths would "bottleneck" due to simultaneous events occurring in various parts of the region.

c. Near the end of this decade, low earth orbit satellites, or LEOs, will provide dynamic bandwidth on demand. This class of transmission service will be priced at a premium but should allow for easy video access from virtually anywhere on earth with small lightweight equipment that is easily transported as passenger aircraft baggage.

d. The new buzzword will be "multi-media" where computers that access advanced ISDN services are used to route and collect and edit video news material from diverse global sources. The computer terminal, or work station, will manage this flow, replacing the video-tape editing rooms of today and will incorporate an integrated and shared newsroom database. Finished products will again be delivered via ISDN to our clients' final hub. Multi-media will also give our clients instant access to archival news material so breaking news stories will be easily capable of showing historical perspectives.

The changes implied by the re-invention of "video media" are, at first glance, deeply challenging if not frightening. We see established networks and divested former telecommunications monopolies struggle to hold their

own in a changing world. Change - where there was once perceived stability.

I believe that the mix of businesses which we are colleagues in is an industry simply based on information flow, perhaps the most rapidly growing industry of our time.

Its beginnings trace to the dawn of spoken language and its first technological breakthrough was possibly smoke signals. Its future is as boundless as its past.

PACIFIC TELECOMMUNICATIONS CONFERENCE '92
Remarks for Mr. Ronald J. Mario
President of COMSAT Mobile Communications
Wednesday, January 15, 1992

Good afternoon ladies and gentlemen. I'm Ron Mario, President of COMSAT Mobile Communications, which serves as the U.S. partner and largest owner in the international organization known as Inmarsat. COMSAT is based in Washington, D.C., and is the largest provider of mobile satellite communications services around the world.

The organization was originally called COMSAT Maritime Services, but is now called COMSAT Mobile Communications, since it has added Aeronautical and Land Mobile to its family of mobile communications services.

My remarks today will focus on just those issues that effect Mobile Satellite Communications (MSS), but I believe they will be pertinent since spectrum allocation for mobile communications is such an important topic at next month's World Administrative Radio Conference.

The key message that I'd like to get across to you and to everyone who may have an impact on the outcome of the WARC is that competition is healthy for the mobile communications industry, but the extremely limited amount of spectrum that is available for mobile satellite services is limiting the potential for competition. For there to be true competition, customers need to have a choice among services and suppliers, but the limited spectrum available severely limits those choices. This issue will become critical in the very near future as the demand for mobile communications continues to grow.

Sixteen years ago COMSAT launched the world's first mobile communications satellite to provide ships at sea with a way to communicate that was reliable, private and accessible 24 hours a day from any location in the world.

Five years later, about the same time Inmarsat was formed, there were 1000 users of the system. Today, that number has grown to 18,000. And that number is expected to grow exponentially in the next two to five years as we bring on smaller, more portable and less expensive mobile terminals. They have the potential to revolutionize the way we communicate around the world.

We've already started to see the explosion in growth from many different directions: From private and commercial aircraft that need instant communications with ground control or their home office; from reporters like Peter Arnett of CNN using land transportable satellite communications to cover Persian Gulf developments as they occurred; from Red Cross volunteers helping disaster victims get back on their feet after a devastating earthquake.

The explosion is also coming from individual consumers who have already started to equip their pleasure craft with smaller, more affordable Inmarsat-C text messaging services. And they will soon be able to take advantage of low-cost digital voice, fax and data services from the upcoming Inmarsat-M service, which COMSAT will be introducing later this year. These services will bring the benefits of reliable communications via satellite to hundreds of thousands of consumers all over the world.

There are also a half dozen companies developing the systems that will allow hand-held devices to operate over satellites in the very new future. And some, like Inmarsat, are targeting these systems to be available before the end of this century. People will be able to take the hand-held terminals anywhere, and use them anytime--to call London or Moscow or Cairo. They can take then with them when they go to the Aleutian Islands or to Tonga--and they'll be able to communicate the same way that you and I communicate each day, when we pick up the telephone to call our spouse, or send a fax to a

1282

business associate half-way around the globe. Some of these systems will use geosynchronous satellites (GSO); some may use Low Earth Orbit, or LEO, systems; and some may use High Elliptical Orbits (HEO) or a combination of systems.

But regardless of which systems are used, the actions that will be taken at the up-coming WARC could have far-reaching effects on not only Inmarsat and COMSAT, but on the plans of all the other hopeful Mobile Satellite service providers waiting in the wings to see how much spectrum will be made available for these services.

The available spectrum for mobile communications is in critically short supply, and that is the single biggest barrier to allowing new service providers onto the scene. It ultimately may not matter which organization is allocated the spectrum, because there is only enough to offer a limited range of services and not enough to create the volume necessary to significantly reduce prices for the customers who want and need the service.

To illustrate how little capacity is available today for Mobile Communications: did you know that the entire mobile community today -- and I'm referring to all existing or authorized mobile systems including Inmarsat, Aussat, the Soviets and AMSC, combined -- operate on the equivalent of 1 transponder on 1 INTELSAT satellite? INTELSAT, by the way, has 16 satellites with 27-48 transponders per satellite. These mobile systems use about 30 MHz of spectrum, compared to INTELSAT's 575 MHz at C-band plus 500 MHz at K-band.

It is in the public interest for new companies to enter the mobile market, but they can't without taking spectrum currently allocated to other mobile service providers, because we're all competing for a very scarce

resource. Therefore, many of the issues facing us at next month's WARC are crucial to the entire mobile industry's survival. And here's what we at COMSAT would like to see happen there:

1) A mobile satellite allocation for LEO satellites in the RDSS Bands: 1610-1626.5 and 2483.5-2500 MHz--plus a secondary allocation (space to earth) for MSS in 1613.8-1626.5 MHz.
2) Additional spectrum made available for geosynchronous mobile satellites. To meet the extensive demand forecast by the CCIR, we need a minimum of 125 MHz of new spectrum by 2010.
3) The best result would be enough spectrum to accommodate both LEO and GSO satellite systems, so customers truly have options.
4) We must also protect safety-related services in the existing L-band: GMDSS in Maritime (lower 14 MHz L-band) and Aeronautical communications related to safety and regularity of flight in the Aeronautical band (upper 10 MHz L-band)--these are special obligations that Inmarsat and the U.S. (Coast Guard/FAA) share.

We believe these actions will serve all the Mobile Satellite service providers and will offer the most opportunity to expand competition in the industry. Thank you.

OUTLINE OF REMARKS BY

PETER MARSHALL
PRESIDENT, KEYSTONE COMMUNICATIONS
USA

AT
PACIFIC TELECOMMUNICATIONS CONFERENCE
14 JANUARY 1992

(SESSION NO. 3.2.4.3)

1235

400 North Capitol, N.W., Suite 177
Washington, DC 20001
Telephone (202) 737-4440 FAX (202) 783-5166

This panel does not include a speaker from INTELSAT, which obviously has an important role in considering the subject of Regional satellite systems for the Pacific. I do not intend to speak for INTELSAT - there are others here from that organization who will do so effectively in other panels. But I will try to add an INTELSAT perspective to our discussion. I do so as a former executive of INTELSAT, and now, in my new capacity, as a major user (not for the first time).

Keystone has recently signed a contract with COMSAT and KDD for the full time lease of an INTELSAT Pacific Region transponder to provide video services from the US to Japan and to other Asian countries. I am and have always been in favour of private systems and competition in the international satellite market. I want to see choice and competing services and innovation which will stimulate the market and help it to grow even faster. I applaud the success of ASIASAT in this region and PANAMSAT in the Atlantic; and I welcome the endeavours of Mat Nilson and all the others who have been planning international satellite ventures here for so many years. But my files are full of statements and forecasts about start-up dates which have not been fulfilled. I sympathise with TONGASAT and PACSTAR and CELESTAR, FINANSAT, and COLUMBIA and understand the problems which they and their promoters have continued to face as they tangle with Governments and PTTs who have controlled telecommunications for so long. So often it is one step forward and two steps back - hopes and promises fulfilled or delayed. So when Keystone decided to enter this market it was still Hobson's choice - INTELSAT or nothing if we were to start the business now. I would have dearly loved to have some options, some competitive quotes for the space segment - and I might still have chosen INTELSAT because of its coverage and connectivity, the potential for back-up capacity and for future expansion. But in the real world, away from the conference and press reports, there is still no choice in 1992 for transpacific services.

Despite all their problems with capacity shortages, INTELSAT has managed to meet most requirements for video leases and other non-voice services by juggling with transponder assignments and by building up confidence in their inclined orbit satellites. The broadcasting users viewed the prospect of inclined orbit very reluctantly, even with hostility, at first - I remember it well, I was there at INTELSAT when we first discussed this solution with the users. But when there is no real alternative, even the broadcasters became pragmatic and looked at the benefits of lower tariffs while the engineers coped with the technical requirements. Now there are even those in the industry who are so conditioned by the experience that they are asking whether the economics of fixed station-keeping are really justified? How about putting new satellites into inclined orbit straight away and providing services based on a 20 or 25 year satellite operating life? That certainly alters the satellite vs. cable cost argument. The instinctive reaction is to say "no way" - this would be offering second-class service in a market used to high grade engineering standards. But stranger things have happened and it would not surprise me if extended life satellites (that's a more palatable description than inclined orbit) became at least a part of the permanent satellite system - whether they are operated by INTELSAT or by the private sector.

Of course, INTELSAT's need to consider this option and indeed their ability to compete in this region for the rest of the decade - will depend to a great extent on the successful launch of the new INTELSAT - 7 series, and on the recovery and relaunch this spring of the INTELSAT - 6 which is still stranded and in low earth orbit. If they have 100% success with the launch program in the next couple of years, they will be able to recover from the current capacity shortages in the Pacific, for transoceanic and regional services. They will also be able to expand and develop new services including the additional Ku-band spot beams on the sevens. The private system operators - including those here on this panel today - must now be planning to enter a

marketplace in which a revived and strengthened INTELSAT will be competing. The window of opportunity to exploit INTELSAT's capacity shortage is probably closing. Hindsight is easy, but if PANAMSAT or any others had been able to finance new satellites for this region five years ago, and had been able to pressure the regulatory mandarins in Asia as successfully as they have done in Europe and South America, they would be reaping the benefits today.

But unless INTELSAT runs into further capacity problems through launch failures, I think that opportunity has now gone and the realistic scenario for the rest of the 90s is one in which those private operators who actually get into business will be competing principally in the specialized markets - such as video, VSAT services, INTELSAT and its members will continue to dominate the public switched networks and those services which require universal coverage, where they will also increasingly compete with the undersea cable systems.

Within this scenario, there are certainly welcome signs of change and relaxation of the regulations in some Asian countries, sufficient to encourage me to take the first steps with Keystone to enter the video transmission services market. The concept of service providers and space segment resellers has been one of the elements in stimulating the growth of the industry in the US. The same concept has become successful in the Atlantic region through Brightstar. And now, the opportunity has come to start something similar in the Pacific Region.

The Asian countries are changing and opening up their telecommunications markets - but slowly and carefully, according to their own agendas and their own needs. As American car manufacturers learned the hard way last week, apparently to their surprise, Asia is different. As everyone on this panel knows, business

relationships there are built slowly and patiently and professionally. That way, in time, there will be alternatives available in the Region, and when Keystone needs a second or third transpacific transponder, we will be able to have a real choice. I look forward to that day.

BIOGRAPHICAL NOTES

Peter Marshall has more than 25 years of experience in senior positions in the broadcasting and satellite communications areas, working in both public and private sectors.

He was recently appointed President of Keystone Communications, a US-based satellite transmission services company which provides US domestic and international video service, mainly for broadcasting and business communications uses. He was formerly with INTELSAT in Washington, DC.

Mr. Marshall is British, and after service as an officer in the Royal Navy, he began his career in broadcasting with the BBC. He then moved to Visnews Ltd., the London-based international news and communications company, where he became General Manager and CEO. During this period, he was closely involved in the development of satellite distribution for broadcasters throughout the world. He also created Brightstar Communications, the first company to lease international satellite capacity for third party traffic.

This experience led to his appointment in 1986 to INTELSAT in Washington, DC as Deputy Director, Broadcast Services. INTELSAT is an international cooperative organization of 117 member nations. It owns and operates a global system of 13 communications satellites which provide voice, data and video services to users in 170 countries of the world. At the end of 1988, he joined a Washington, DC telecommunications consulting group.

Mr. Marshall's career has spanned many aspects of television and international communications, and he developed a wide range of industry contacts in the UK, USA and many other countries.

Mr. Marshall was vice Chairman of the Royal Television Society in 1984 and 1985 and was elected Chairman in 1986. He was a founder member of the UK Space Society and is President of the Washington-based Society of Satellite Professionals International.

He is the author of a number of papers and articles, notably on the role of satellite communications in the development of international broadcasting; and he has presented papers on related subjects at conferences in the United States, Europe and Japan.

Remote Telemetry Applications in Micronesia

MCCONNELL, J.; B. R. BEST
University of Guam, Mangilao Guam 96923

SUMMARY

The University of Guam College of Agriculture and Life Sciences has been exploring the use of a specialized packet modem data transfer package designed to relay remotely logged field data to a central hub in the Micronesia Islands. The data can then be transferred to other sites via the GOES PEACESAT system. Incorporated with the Mallard electronic mail system (see Cohen et al. PTC'92), remote data can be forwarded around the islands and internationally.

Originally, the authors designed the system with a packaged packet modem system and sensors. The sensors collect data on the environment and plants. Field modifications have enhanced the system for use with a Macintosh computer for Micronesian experimental applications. Software was developed for automatic local data retrieval. This system will link remote solar powered UHF RF links through the local loop or simplex VHF or HF radio into the district or state educational GOES PEACESAT uplink to be received by other similarly linked Pacific Island experimental field sites.

Previous Micronesian computer/voice-integrated networking experiments were carried out through the PEACESAT ATS-1 satellite and commercial carriers. The high cost and lack of local loops in Micronesia have made normal BBS or duplex systems infeasible. This paper will review the problems encountered and the benefits of this remote electronic mailbox network.

KEYWORDS: AGRICULTURE, DATA TRANSFER, PACKET RADIO, SOFTWARE, MACINTOSH

INTRODUCTION

During the past few years we have used various equipment which produce large quantities of data. It is becoming increasingly common to interface the equipment to computers. The level of communications between the equipment and the computer varies greatly ranging from simple data transfer to allowing complete remote control. We have used equipment with various levels of communications abilities. I would like to describe 3 types of equipment we have used.

HPLC

The HPLC is used for the separation of various compounds in liquids. This particular system is controlled by a Macintosh. There is a control box which connects to the serial port. The computer controls the equipment and also stores data. Two different data loggers are currently used for collection of weather data. Weather data is important in agriculture for identifying plant responses to treatments under various environmental conditions.

DATA LOGGERS

Two types of data loggers have been used. One type is a small self-contained unit that must be removed from the field and brought into the lab for connection to a computer. A standard communications program is used for data transfer It is very easy to set up the logger however it has limited flexibility for customization. This logger is good for short term data logging. It has the capacity to store about 3 months of data. A modular, multi-component system is the other type of logger we are using. This system has increased flexibility. Many options are available for configuring sensors. The format for the storage and transfer of data are also flexible. There are two main formats of data storage and transfer:

1. EPROMS. Data is stored in removable EPROMS. The EPROMS are removed from the logger and taken to a reader which is attached to a computer. The disadvantage to this method is that the EPROM must be removed from the unit to transfer the data and for erasing the memory. The advantage is that the storage is non-volatile.

2. RAM packs. This is volatile memory and data stored will be lost with loss of power to the logger. Data transfer is either accomplished by directly connecting a computer to the logger in the field or by remote connections. The data is can be transferred via telephone lines or radio. It was desired to make the transfer of data from the weather stations as easy and efficient as possible. It

was decided to set up the weather station for remote data transfer. Along with data transfer, data storage is an additional consideration.
Today I would like to describe our weather station configuration and show our software we use for storing the accumulated data.

Logger Configuration

Due to current limitations with telephones on Guam, it was decided to use radio with packet modems. An additional advantage is the flexibility of moving the location of the station allowed with radio. With telephone connections, a telephone line needs to be installed to each site. Originally, the system was installed with a packaged packet modem system and sensors. The sensors collected data on the environment and plants. This communication package was a commercially available. Once this system was installed and in operation, the communications system was customized with locally available components.

Software description

As mentioned earlier, besides developing the means to conduct remote data transfer a database was developed to store data. The database was developed to store information on agricultural experiments. 4th Dimension was customized for this purpose.
There are multiple files in the database. It is a multi-purpose database that stores different types of data including weather data. I would like to describe some of these features. The database has been under development for 5 years. Among the goals was the desire to have an easy to use interface. The basic layouts have buttons in similar locations. It was set up to function like HyperCard.

Accessions

One file is basically a plant inventory (Figure 1). Information is stored on plant material. Much of the plant data is on orchids such as this dendrobium. As new plants are entered into the database, a unique ID number is assigned by the computer to each plant.

Experiments

Another set of files handles the definition of individual experiments. Each experiment is entered as an individual record. There are multiple screens included in each record (Figures 2-5). Data related to the experiment is entered into the specific record. Once entered, the data is posted to another file where all plant data is stored. These are some of the screens included in the experiment record. Figure 2 is the layout for defining the treatments and the parameters that will be recorded. Information such as the interval of data taking is entered. Once the treatments are entered, the plants are assigned to the experiment (Figure 3). This shows the plants that have been assigned to the experiment. Clicking on the Add plants button calls a window which shows what plants are available (Figure 4). Finally this is a Spreadsheet used for data entry. The column headings are defined from pop up menus (Figure 5). Once the data is entered, it is posted to permanent records in another file and this sub-file is cleared.

Weather Data

The weather data files were developed to allow storage of data from multiple loggers in one database. The original design was solely for importing data into the database after it had been transferred with a communications package
More recently communications features have been added for direct transfer from the logger to the database. There are multiple files associated with defining a weather station. One file handles the configuration of loggers. One record is entered for each logger station
The record contains fields for:

- Name of logger
- Location
- Other description
- Number of reports from a logger
- The Li-Cor store one report
- The Omnidata can store 3 with different variables and report intervals
- A sub-record stores information on each of the reports (Figure 6).
- 1 to 10 fields of data are defined per report
- The name of the field
- The type of data--instantaneous, average, sum, maximum, minimum
- Interval reported
- The database generates an ID to assign to the various reports

Once a weather station is defined, the database will connect to the weather station at the designated time. Once the connection is

established, data is transferred and the loggers memory is cleared and then the communication is disconnected. This is all accomplished by the database.

The entire system is capable of being battery powered. The weather stations are solar powered. During the last typhoon, the weather data was transferred the day after the storm even though there was no power on the entire island. Figure 7 shows some weather data that is stored in the database. The database has the capabilities of producing graphs of desired data through the use of 4D Calc and 4D Graph. FIgure 8 is a plot of solar radiation data. Figure 9 is a plot of humidity, temperature and wind speed.

DISCUSSION

Difficulties

One of the difficulties we did experience was in powering the weather station. The solar panel originally supplied with the commercial package was found to be too small. This was replaced with a larger panel.

There has been some interference from other sources. This problem was addressed by shortening the packet length.

Uses and Future Goals

One of the attractive features of this system is it flexibility. It is very easy to set up a weather station in a remote site without needing to make frequent trips to the site for data transfer. While currently we are using this system for weather data, this system could be used for the transfer of other types of data. One goal is to explore the use of other radios and to utilize GOES PEACESAT to allow data transfer among islands. Various approaches are currently being explored for allowing the data to be stored on a hub computer that can be transferred as subsets to other sites.

INTRODUCTION

During the past few years we have used various equipment which produce large quantities of data. It is becoming increasingly common to interface the equipment to computers. The level of communications between the equipment and the computer varies greatly ranging from simple data transfer to allowing complete remote control. We have used equipment with various levels of communications abilities. I would like to describe 3 types of equipment we have used.

HPLC

The HPLC is used for the separation of various compounds in liquids. This particular system is controlled by a Macintosh. There is a control box which connects to the serial port. The computer controls the equipment and also stores data. Two different data loggers are currently used for collection of weather data. Weather data is important in agriculture for identifying plant responses to treatments under various environmental conditions.

DATA LOGGERS

Two types of data loggers have been used. One type is a small self-contained unit that must be removed from the field and brought into the lab for connection to a computer. A standard communications program is used for data transfer It is very easy to set up the logger however it has limited flexibility for customization. This logger is good for short term data logging. It has the capacity to store about 3 months of data. A modular, multi-component system is the other type of logger we are using. This system has increased flexibility. Many options are available for configuring sensors. The format for the storage and transfer of data are also flexible. There are two main formats of data storage and transfer:

1. EPROMS. Data is stored in removable EPROMS. The EPROMS are removed from the logger and taken to a reader which is attached to a computer. The disadvantage to this method is that the EPROM must be removed from the unit to transfer the data and for erasing the memory. The advantage is that the storage is non-volatile.

2. RAM packs. This is volatile memory and data stored will be lost with loss of power to the logger. Data transfer is either accomplished by directly connecting a computer to the logger in the field or by remote connections. The data is can be transferred via telephone lines or radio. It was desired to make the transfer of data from the weather stations as easy and efficient as possible. It

was decided to set up the weather station for remote data transfer. Along with data transfer, data storage is an additional consideration.
Today I would like to describe our weather station configuration and show our software we use for storing the accumulated data.

Logger Configuration

Due to current limitations with telephones on Guam, it was decided to use radio with packet modems. An additional advantage is the flexibility of moving the location of the station allowed with radio. With telephone connections, a telephone line needs to be installed to each site. Originally, the system was installed with a packaged packet modem system and sensors. The sensors collected data on the environment and plants. This communication package was a commercially available. Once this system was installed and in operation, the communications system was customized with locally available components.

Software description

As mentioned earlier, besides developing the means to conduct remote data transfer a database was developed to store data. The database was developed to store information on agricultural experiments. 4th Dimension was customized for this purpose.
There are multiple files in the database. It is a multi-purpose database that stores different types of data including weather data. I would like to describe some of these features. The database has been under development for 5 years. Among the goals was the desire to have an easy to use interface. The basic layouts have buttons in similar locations. It was set up to function like HyperCard.

Accessions

One file is basically a plant inventory (Figure 1). Information is stored on plant material. Much of the plant data is on orchids such as this dendrobium. As new plants are entered into the database, a unique ID number is assigned by the computer to each plant.

Experiments

Another set of files handles the definition of individual experiments. Each experiment is entered as an individual record. There are multiple screens included in each record (Figures 2-5). Data related to the experiment is entered into the specific record. Once entered, the data is posted to another file where all plant data is stored. These are some of the screens included in the experiment record. Figure 2 is the layout for defining the treatments and the parameters that will be recorded. Information such as the interval of data taking is entered. Once the treatments are entered, the plants are assigned to the experiment (Figure 3). This shows the plants that have been assigned to the experiment. Clicking on the Add plants button calls a window which shows what plants are available (Figure 4). Finally this is a Spreadsheet used for data entry. The column headings are defined from pop up menus (Figure 5). Once the data is entered, it is posted to permanent records in another file and this sub-file is cleared.

Weather Data

The weather data files were developed to allow storage of data from multiple loggers in one database. The original design was solely for importing data into the database after it had been transferred with a communications package
More recently communications features have been added for direct transfer from the logger to the database. There are multiple files associated with defining a weather station.
One file handles the configuration of loggers.
One record is entered for each logger station
The record contains fields for:

- Name of logger
- Location
- Other description
- Number of reports from a logger
- The Li-Cor store one report
- The Omnidata can store 3 with different variables and report intervals
- A sub-record stores information on each of the reports (Figure 6).
- 1 to 10 fields of data are defined per report
- The name of the field
- The type of data--instantaneous, average, sum, maximum, minimum
- Interval reported
- The database generates an ID to assign to the various reports

Once a weather station is defined, the database will connect to the weather station at the designated time. Once the connection is

established, data is transferred and the loggers memory is cleared and then the communication is disconnected. This is all accomplished by the database.

The entire system is capable of being battery powered. The weather stations are solar powered. During the last typhoon, the weather data was transferred the day after the storm even though there was no power on the entire island. Figure 7 shows some weather data that is stored in the database. The database has the capabilities of producing graphs of desired data through the use of 4D Calc and 4D Graph. FIgure 8 is a plot of solar radiation data. Figure 9 is a plot of humidity, temperature and wind speed.

DISCUSSION

Difficulties

One of the difficulties we did experience was in powering the weather station. The solar panel originally supplied with the commercial package was found to be too small. This was replaced with a larger panel.

There has been some interference from other sources. This problem was addressed by shortening the packet length.

Uses and Future Goals

One of the attractive features of this system is it flexibility. It is very easy to set up a weather station in a remote site without needing to make frequent trips to the site for data transfer. While currently we are using this system for weather data, this system could be used for the transfer of other types of data. One goal is to explore the use of other radios and to utilize GOES PEACESAT to allow data transfer among islands. Various approaches are currently being explored for allowing the data to be stored on a hub computer that can be transferred as subsets to other sites.

NYNEX'S CUSTOMER ACCESS NETWORK

Emmett E. McDonough
Telesector Resources Group, Inc.
NYNEX Corporation
White Plains, New York

ABSTRACT

NYNEX's Customer Access Network is currently undergoing a major modernization program. In order to support NYNEX's VISION of deploying an Intelligent Broadband Communications Network, NYNEX wants to accelerate the deployment of fiber based systems in the local loop. This Fiber In The Loop (FITL) program will ensure NYNEX's being strategically positioned to be our business and residential customers' carrier of choice for their full complement of network services.

This briefing will expand upon the aforementioned FITL program. NYNEX's FITL trials of the Raynet LOC-1 System and the BroadBand Technologies, Inc's (BBT's) FLX-100 System will be highlighted. Results and lessons learned from these trials will be presented, emphasizing the criticalness of system costs, operations and loop powering. this report will address the strategic role SONET terminals, Passive Optical Networks (PONs) and wireless technologies (e.g., PCN) will play in the realization of NYNEX's Network VISION. NYNEX's Cable Television (CATV) operations in the U.K. will also be discussed as an alternative loop architecture.

INTRODUCTION

The global telecommunication industry is rapidly evolving towards the deployment of an Intelligent Broadband Communications Network. This Network VISION will enable network providers to satisfy their customers' demands for bandwidth diversity, service portability, user control and simplified user interfaces. Technology advancements in the areas of broadband, wireless, network intelligence and ergonomics provide a one for one correlation to the aforementioned service characteristics:

SERVICE	TECHNOLOGY
Bandwidth Diversity	Broadband
Service Portability	Wireless
User Control	Network Intelligence
Simplified Interface	Ergonomics

This paper will place major emphasis on the first two technologies - broadband and wireless; and how NYNEX plans to deploy Fiber-In-The-Loop (FITL) and wireless technology in its local loop network.

NYNEX's evolution to that broadband infrastructure has, in fact, already started in its facilities networks - interoffice and subscriber loop. NYNEX has deployed over 500,000 fiber miles in its network. Most of that deployment has been in the interoffice network, with a recent increase in the installation of fiber in the feeder plant. NYNEX's deployment of lightwave technology has been strategically targeted. It has focused on areas that are characterized as possessing accelerated market demands, potential competitive pressures and/or modernization requirements. The planning of NYNEX's fiber network is an integrated marketing, technology and operations effort. NYNEX's multiplexing strategy and its Operations Support Systems infrastructure ensures not only the cost effective deployment of technology, but also its efficient management.

NYNEX's infusion of broadband capabilities in its facilities network will continue. Nevertheless, one of NYNEX's biggest challenges is to accelerate the penetration of fiber-in-the-loop, especially in the distribution plant. NYNEX's drive to push broadband capabilities to all of its customers is hindered greatly by the bandwidth limitations of its local loop. NYNEX's local loop is predominantly narrowband (i.e., 64 kb/s). It has a tremendous amount of embedded copper plant. NYNEX's deployment of fiber in the loop constitutes a very small percentage of its loop infrastructure. As technology evolves, so does customer demand for more and more bandwidth (see Figure 1). The loop must be upgraded to the point where NYNEX is strategically positioned to provision, on a general deployment basis, those services requiring greater amounts of bandwidth. The answer is a fiber based customer access network!

TARGET LOOP ARCHITECTURE PLAN

Realizing that services and technology are evolving towards broadband and that several alternative FITL architectures exist as well as a plethora a systems vendors who would be vying for NYNEX's business, NYNEX has spent the last few years developing its target loop architecture. NYNEX's target loop (see Figure 2) will be fiber based and fully SONET compatible. The critical elements of the evolving local loop are:

- Next Generation Digital Line Carrier (NGDLC)
- SONET Add/Drop Multiplexer in Feeder
- TR-303 Standards Compliance
  - TSI Capability
  - Remote, Automatic Provisioning Capabilities
  - Automated Administration Capabilities
- Multiple Switching Machines Integration
- Standard OS/NE Interfaces
  - Enhanced OSSs (with Customer Control)
- Standard P1396 SONET Backplane
- Various Distribution Modules
  - "Traditional" DLC with Programmable Channel Units
  - Fiber To The Curb (PON)
  - Wireless
  - SONET Extension to Customers
  - Intelligent

The feeder portion of the local loop will constitute a physical ring, which will be fiber lean via a logical ring. The distribution segment of the loop will use a topology forming a physical star, which will also be fiber lean - but, via passive optical splitters. This local loop will be upgradeable to broadband.

FITL ARCHITECTURE REQUIREMENTS

NYNEX has conducted a series of meetings with numerous system vendors to explore those vendors' respective views on local loop evolution, as well as the particulars of their specific FITL systems. NYNEX has also issued an RFI (Request For Information) to the vendor community. This RFI delineated NYNEX's strict requirements for FITL systems to be as follows:

- Fiber based systems must provide cost and service parity to copper equivalent systems for narrowband services.

- Fiber based systems must provide a platform from which to evolve towards broadband and to deploy complementary loop technologies.

- Efficient network management capabilities must accompany these systems, whereby operations, administration and maintenance are enhanced.

FITL TRIALS

NYNEX has conducted or is in the processing of conducting two field trials of a FITL System. These field applications are the New England Telephone (NET) trial of Raynet's Loc-1 System in Lynnfield, MA; and the New York Telephone (NYT) trial of BroadBand Technologies' FLX-100 System in Poughkeepsie, NY.

Raynet:

The first system to qualify for a NYNEX field Application is Raynet's Loop Optical Carrier (LOC-1) system (see Figure 3). The Raynet system is a bus architecture which employs a non-invasive coupler at the far end electronics site. LOC cost models are consistent with NYNEX's cost per line targets. An enhanced network management system is integral to LOC.

The NYNEX FTTC application was conducted in Lynnfield, Massachusetts. It entailed the provisioning of 130 lines to a 100 home development, which was an existing neighborhood. This rehabilitation project (REHAB) was consistent with NYNEX's goal to modernize its network with cost effective, state-of-the-art technology. The loop length of this area was 13.9KFT.; thus, a remote terminal (RT) was required. The RT was located in a controlled environmental vault (CEV); it housed a NEC 1840A 135 Mb/s fiber optics transmission system, LOC's head end (office interface unit) and ancillary equipment. This application provisioned telephone services only. The field evaluation with in-service customers began in January 1990 and concluded in October of that same year.

Raynet's LOC-1 comprises six (6) system components; Office Interface Unit (OIU); Subscriber Interface Unit (SIU); Optical Transport; Remote Power Supply (RPS); System Administration Module (SAM); and the Remote Intelligence Distribution Element Support (RIDES) System. The OIU is an intelligent network element that serves as the centralized intelligent node for system configuration and monitoring. It also provides an interface to the fiber optic bus. The SIU is a field deployable fiber optic based remote intelligent network element. It is used to provide narrowband (and eventually broadband) services to the customer. The non-invasive coupler is housed in this unit. The optical-to-electrical conversion as well as the interface to copper drop wires (and eventually to coaxial cable crop wires for video transport) is done at the SIU. The Optical Transport is a bus architecture and is provided by two fibers between the OIU and up to 24 SIUs. Each fiber enables a unidirectional bus that is passively tapped at the SIU. The RPS contains rectifiers, back-up batteries, power cables, power pigtails and alarm lines to each SIU on the bus. SAM is a micro-computer and resident software that administers the LOC system. SAM is a micro-computer and resident software that administers the LOC system. SAM functions include line provisioning, testing, alarm surveillance and the collection of historical data pertaining to LOC. RIDES enables remote flow through provisioning, testing, maintenance and alarm surveillance and retention of historical date for one or more LOCs.

NYNEX's field application of the Raynet LOC-1 system provided an opportunity to conduct a comprehensive review of the technological, operational and service provisioning aspects of deploying a local loop fiber distribution system. Some of the areas pursued were the:

- Development of subscriber fiber access experience.
- Evaluation of alternative loop architectures.
- Assessment of operations support system capabilities.
- Validation of cost assumptions.
- Driving of NYNEX's loop architecture evolution.

The planning, engineering and assessment of Raynet's LOC system was conducted by an intercompany project team. The project manager received corporate wide support in his assembling of a professional cadre to make this project the success that it was. Based on the positive feedback from the LOC-1 evaluation, NYNEX may conduct similar trials of Raynet's LOC-2 system, which is a more powerful, flexible and robust system (than LOC-1) for the local loop. The LOC-2 system also employs the flexibility of the Passive Optical Network (PON) concept.

BROADBAND TECHNOLOGIES, INC:

NYNEX also conducted a lab verification of the narrowband version of BBT's Fiber Loop Access (FLX) 100 system at NYNEX's Science and Technology Center in White Plains, New York (see Figure 4). BBT has developed a digital fiber optic transmission system designed initially to carry POTS to residential subscribers and small businesses; and then to be upgraded to carry video. The BBT system achieves cost efficiencies with an architecture which shares electro-optical components and fiber optic cable between several subscribers.

In the BBT POTS system, a signal containing 16 voice circuits is transmitted from a remote terminal to a pedestal, where it is split passively, and shared among multiple subscribers (up to 16 with 4 being average). The BBT system may be deployed in single star, double star or triple star architectures. In the single star architecture, the BBT Remote Distribution Terminal (RDT) is located in the central office, thereby negating the need for a field deployed remote terminal.

The BBT system consists of the following basic elements:

- The transmission medium, which is a single mode fiber cable, carries signals between a central distribution point and the subscriber. The central distribution point, called the BBT RDT is normally located in the field (remote terminal) but can be located in the telephone company central office.

- Electro-optical devices housed in the ONU's. This element connects the customers to the remainder of the BBT system and converts the optical signal from the fiber to electrical signals used by the telephone and vice versa.

- Electro-optical devices housed in the BBT RDT located in the C.O. or at a remote terminal location. The BBT RDT connects the BBT system to the telephone company network and manages the connection.

- Passive optic splitters are utilized in the BBT FTTC architecture. The splitters are normally located at the curbside and allows sharing of the fiber optic cable.

1302

- Operations Interface Module (OIM) is a supervisory system which allows for integration of the FITL system into the current telephone company environment. It will be migratable to emerging generic requirements such as TR-303, SONET, etc. A single OIM provides supervisory functions for several BBT systems and acts as a gateway between these systems and various telephone company operations support systems.

This lab verification was completed with satisfactory results; and NYNEX is in the process of conducting a comprehensive field evaluation of the BBT System in Poughkeepsie, NY.

The Poughkeepsie trial, which encompasses 400 living units that account for 470 lines, is the largest NYNEX FITL project to date. The site itself is an area targeted for rehabilitation by NYT. This existing neighborhood calls for the BBT system to be deployed in both aerial and buried configurations. Telephone service is scheduled to be provisioned via BBT's FLX-100 system during 1Q92.

U.K. CATV OPERATION

NYNEX Network Systems (NNS) is developing a telecommunications and cable television business in the U.K. They are the majority partners in eleven franchises, which account for approximately 1.4 million homes passed. NNS officially opened its Portsmouth franchise (along the southern coast of England) in September 1991, when they provided CATV service to customers. They are scheduled to offer telephone service to its customers during 1Q92.

The network architecture being initially deployed in NNS' UK franchise is one that can provision both telephony and video services. The network, which is fiber based, utilizes separate systems for telephony and video that are overlaid on each other (see Figure 4). Efficiencies and economies of scale are achieved by utilizing shared headend/central office facilities, street cabinets and conduit systems. The operations support system is also evolving towards a single-integrated system that will manage both networks and classes of service. As technology matures, NNS' network will become more integrated at the system level.

CONCLUSION

Fiber Access Strategy

NYNEX's assessment of Raynet's LOC system and BBT's FTTC system are the first in a coordinated series of fiber system evaluations. These tests will come both in the form of lab verifications and field applications. The goal of this corporate action will be a resulting understanding of which local loop fiber distribution systems are best suited for the NYNEX environment. Vendor selection and product approval will follow, as well as the establishment of general deployment guidelines.

These fiber system evaluations are critical elements of NYNEX's customer access network strategy. Briefly, this strategy is as follows:

- Continue to evolve NYNEX's fiber network.
- Conduct marketing and technology fiber trials.
- Drive vendors to meet NYNEX's service concepts, technology and operational requirements.
- Accelerate fiber deployment in targeted areas.

This paper has defined NYNEX's FTTC trial program, which will enable and enhance the evolution of our Vision of an Intelligent Broadband Communications Network. Technology and the marketplace are converging and evolving at a rapid pace. Without an equally enlightened evolution of the regulatory/judicial/legislative arena, the achievement of theat Vision will be delayed.

Restricting regulations must be loosened at the federal and state levels (e.g., MFJ restrictions concerning information content and manufacturing, accounting rules, depreciation schedules, price cap regulations, Telco/CATV crossownership rules, etc.) to create that positive political environment which will facilitate the actualization of a fiber based loop infrastructure in not only the NYNEX territory, but the entire U.S. NYNEX's conduct of its FTTC trial program and the resulting analyses are instrumental input to the overall plan to attain those alternative forms of regulatory policy.

ACKNOWLEDGEMENTS

The author wishes to thank the many colleagues who have contributed towards this paper - particular Bob Froelich and Dave Petruziello of NYNEX's Science and Technology; , Bob Boucher, Bill Judge, and Tom Juris of the Telesector Resources Group; George Ballog and Dave Lowe of Raynet; and Salim Bhatia and Rick Jones of BBT - for their invaluable assistance.

The COMSAT Model for Signatory Representation

Maury J. Mechanick
COMSAT World Systems
Washington, D.C.

1. ABSTRACT

This article examines the essential features of the COMSAT model for Signatory representation, as it operates in the INTELSAT environment, and how that model has advanced overall U.S. commercial and national policy interests. The COMSAT model for Signatory representation has afforded numerous advantages and benefits within the U.S., which have facilitated the desired evolution of a competitive marketplace for the provision of satellite-based, international end-user services.

2. INTRODUCTION

2.1 Considerable attention has recently been focused on models for Signatory representation in international satellite organizations such as INTELSAT, INMARSAT and EUTELSAT, driven largely by worldwide trends towards privatization and deregulation. The U.S. has always had a privatized Signatory, Communications Satellite Corporation ("COMSAT"). The U.S. experience in this regard has been characterized by a level of competition in the satellite-based, international end-user services market far exceeding that achieved (or even contemplated) in any other country. The "COMSAT model" for Signatory representation has been a critical linchpin of this competitive environment, while simultaneously serving to maximize collective U.S. interests in the international satellite organizations in which the U.S. participates.

2.2 This article examines the essential features of the COMSAT model for Signatory representation, as it operates in the INTELSAT environment, and how that model has advanced overall U.S. commercial and national policy interests.

3. ESSENTIAL FEATURES OF THE COMSAT MODEL FOR SIGNATORY REPRESENTATION

3.1 The following constitute the essential features of the COMSAT model for Signatory representation as it presently exists in the United States:

- COMSAT, in its capacity as U.S. Signatory, is a private company, rather than a governmental entity, whose principal INTELSAT-related business activity is the provision of space segment resources, available on a nondiscriminatory basis to all U.S. carriers and users (collectively "U.S. operators").

- COMSAT is incentivized, principally through marketplace/ commercial forces (and, to a lesser degree, through regulatory oversight), to seek to maximize benefit of INTELSAT system for all U.S. operators at a reasonable cost.

- COMSAT has acquired extensive expertise in dealing with all phases of INTELSAT operations, upon which U.S. operators can call as they need assistance.

- COMSAT is fundamentally uninvolved in the domestic regulatory aspects of the provision of international end-user services in the U.S.

- The COMSAT model for Signatory representation has facilitated low-cost entry into the competitive telecommunications sector.

4. BENEFITS PROVIDED BY THE COMSAT MODEL FOR SIGNATORY REPRESENTATION TO U.S. COMMERCIAL INTERESTS

4.1 As a result of the COMSAT model for Signatory representation, a number of commercial advantages accrue to U.S. operators that access the INTELSAT system. These advantages include the following:

- COMSAT, through participation in the INTELSAT Board of Governors' activities, develops INTELSAT policies, programs, services and charges intended to benefit the interests of U.S. operators as a whole, and to be responsive to individual U.S. operators' requirements to the maximum extent possible.

- COMSAT seeks development of optimum operational plans to assure that maximum space segment capacity is available for all U.S. operators. COMSAT serves as the head of the U.S. Delegation at Operations Representatives ("Ops Reps") meetings, assures the establishment of coordinated (among all U.S. operators) U.S. positions on all operational matters considered at those meetings, and seeks approval at those meetings of the coordinated U.S. positions.

- COMSAT commits considerable resources and expertise to activities related to the planning and development of future system capacity in anticipation of expanding, shifting and evolving U.S. operator requirements.

- COMSAT maintains a network control center which is manned on a twenty-four-hour-per-day basis, thereby allowing for around-the-clock submission of and processing of service orders and activations, as well as trouble-shooting activities.

- COMSAT provides technical support and expertise for a number of developing countries and provides technical support through COMSAT Laboratories to advance satellite technology and knowledge, and to increase the quality and availability of international satellite communications.

- COMSAT actively participates in INTELSAT intersystem coordination matters involving all U.S. domsats and U.S.-registered separate systems, and has made available world-class technical resources to facilitate the successful completion of the technical aspects of such consultations. To date, there has not been a single U.S.-initiated intersystem coordination with INTELSAT that has not been successfully concluded.

- In crisis situations, such as the Persian Gulf situation, COMSAT has effectively served as a single interface point with INTELSAT to best represent collective U.S. interests in obtaining satellite services.

5. BENEFITS PROVIDED BY THE COMSAT MODEL FOR SIGNATORY REPRESENTATION TO U.S. NATIONAL POLICY INTERESTS

5.1 The COMSAT model for Signatory representation also provides a number of benefits to U.S. national policy interests, as they relate to

expanded availability of international telecommunications services generally to U.S. users. The advantages to U.S. national policy interests flowing from the COMSAT model for Signatory representation include the following:

- Maximization of total U.S. use of the INTELSAT system.

- Assurance that one U.S. operator does not attempt to thwart or discourage access or use of the INTELSAT system by another U.S. operator.

- Assurance of lowest prices to all U.S. operators by taking optimum advantage of INTELSAT bulk offerings now available under resource-based pricing and equitably sharing the benefits of these price breaks with all operators.

- Assurance that appropriate space segment resources are available and optimally configured to meet all U.S. requirements.

- Promotion of satellite technology over alternative media.

- Assurance that a low cost satellite option to facilitate market entry by new entrants is available.

- Encouragement to other Signatories to provide favorable access arrangements and operating agreements to all U.S.operators.

- Safeguarding of overall U.S. interests on a collective basis.

6. CONCLUSION

6.1 While circumstances vary from member country to member country within the INTELSAT arena, the COMSAT model for Signatory representation has afforded numerous advantages and benefits within the U.S., which have facilitated the desired evolution of a competitively-oriented international telecommunications marketplace. These advantages have enabled the U.S. successfully to promote the development of a competitive marketplace for the provision of satellite-based, international end-user services while avoiding a number of potential pitfalls that are currently being assessed in other countries with regard to the equitable, nondiscriminatory performance of the INTELSAT Signatory function.

Honolulu

Opportunities for the Integration of Telecom and Video Distribution in Hong Kong

by
Stephen Ng
Managing Director
The Wharf (Holdings) Limited, Hong Kong

Wharf

Wharf is one of the major public companies in Hong Kong. Our main businesses are property and franchised infrastructure, including terminals, transport and communications.

Wharf first became involved in Cable TV in 1988 when it joined a consortium to bid for a franchise in Hong Kong. The 5-member consortium was successful. However, as some of you will know, the other 4 consortium members subsequently voted not to continue with the project. That was in November 1990. Since that time Wharf has been working hard to win the franchise, hopefully later this year, that was handed back to the Government.

Television in Hong Kong

Currently Hong Kong has two terrestrial television stations offering a total of two channels in Cantonese and two in English. In addition 5 satellite television channels are licensed and broadcasting.

Telecom in Hong Kong

As the world's gateway to China, Hong Kong is a robust and dynamic place to do business. It is the regional centre for commerce, finance and services in Southeast Asia.

1319

Currently Hong Kong is undergoing a rapid transformation from a heavy dependence on manufacturing to a service centre. Its future prosperity is projected to rely on its service sector which provides over 65% of total GDP and employs over half of the work force.

As some of you already know, the telephone system in Hong Kong is operated by a private sector monopoly: the exclusive licence for domestic telephone services expires in 1995 and that for international telecom in 2006.

Hong Kong has 2.5 million telephone exchange lines and a total of 15,300 international circuits. The number of telephone sets in use, presently 3.1 million, is expected to increase by about 50% by the end of the century. International voice traffic, currently 1500 million minutes with gross revenue of about US$1 billion, is expected to grow by more than 20% each year and international data and fax by about 25%.

Demand for Competition

Although the present telephone infrastructure is advanced and adequate, monopoly means there exists little motivation for improvement. The trend towards a service based economy has made the transmission of information more vital. The customer is ready to go beyond basic telephone service into a more sophisticated telecom environment, in which choices may be made. As with any monopoly-provider environment, there exists a service gap between customer needs and services available.

In a financial community such as Hong Kong, excellent communications are crucial. The business community is crying out for more innovative and sophisticated telecom solutions. Many companies require unique solutions for their telecom problems which the existing service provider cannot or does not accommodate and many networking solutions offered by the telephone company are cost prohibitive.

Recent history in other countries has proven the success of second networks. Hong Kong too will benefit from competition in the local loop. In the competitive environment offered by the introduction of a second service provider, at a minimum the customer will benefit from price and service competition. The larger promise is that it may also bring innovation and a menu of new products and services.

Planning Considerations

With the imminent expiry of the exclusive licence for domestic telephone services any company installing a cable TV network must plan also for the eventual deregulation of telecom in 1995.

The evolution from a cable TV network to a telecom network is natural since the basic infrastructure will be in place. Given the existence of a suitably planned cable network, telecom can be added at a pace which is commensurate with the pace of deregulation and/or consumer demand.

A second network must be designed to meet the demands of the 21st century. This means that we must adopt a network architecture from the outset which will have the capability of evolving to one that can carry all types of signal, whether entertainment or telecom.

In co-operation with NYNEX, we have proposed to the Hong Kong Government a cable TV system delivered initially by microwave (MMDS) to the top of high rise buildings for local distribution by coaxial cable. This we see as a temporary measure to get the service up and running quickly and intend to replace MMDS as soon as possible with fibre.

Optical Fibre

Optical fibre is now the 'medium of choice' for telecom systems around the world, and many of the new services are fibre technology based: image transport, bulk data transport, multi-media services and video-conferencing.

1321

We have no doubt that a network installed today for a modern city has to be based on fibre. The network must also offer an evolutionary path from a purely television distribution network to one which will permit the integration of television and telecom as technology permits.

We are aware that in the last two years fibre-to-the-curb has become widely accepted in the US because it offers early cost parity with copper and provides increased savings in future years. The cost of upgrading the drop becomes quite manageable and can be done as broadband service needs arise. We have in Hong Kong the advantage that we are not planning an upgrade from copper but installing a completely new network based on fibre.

Integration of Telecom and Video Distribution

Historically cable companies and telecom companies operate distinctly different businesses. Although cable TV and telephone networks are inherently different now, they are both independently evolving step by step towards the same goal - a 2-way broadband network which can deliver bandwidth intensive services. Although not a universal view, analyses indicate that the cost of integrated delivery is less costly and of higher quality than separate delivery over today's independent networks.

In many respects the cable and telephone services appear similar to the consumer. Both services are delivered ubiquitously, both provide a way to communicate, both are delivered to the home through a jack on the wall and both services are perceived as basic necessities. With the convergence of cable and telecom we hope to be able to offer both services on our infrastructure in the longer term. A broadband network for cable TV means more channels and more services such as "pay-per-view" and "video-on-demand". In telecom it means a host of broadband switched services such as high speed switched data and multiple media services.

Video Applications

The appetite of consumers for information and entertainment is not expected to diminish. In fact, consumers will expect far more of their communications services as technologies continue to advance. We envisage a future where voice, data and video capabilities will all be interconnected. Consumers will be able to select and use various combinations of services according to their special needs, and at a time that is convenient to them. This customisation will give the consumer more flexibility and control than is available today. A broadband network based on fibre optic transmission is at the heart of this vision.

Switched digital video distribution will allow an exponential increase in the range of programme content available to the consumer. Just as telephone users can be connected to anyone else in the world who has access to a telephone, video switching will enable the user to have access to any programming service that is on the public network. The consumer can exercise a greater choice and control over viewing.

Fibre optic installations are opening up new dimensions in transmission services. Many opportunities will be opened up, limited, possibly, only by our imagination. For example:

Video-conferencing allows business people to reduce or eliminate their travel time. It is currently available in Hong Kong on an as required basis. The fibre based network we envisage would make it readily available. Once it is readily available not only will it be used by businesses, it will also provide a realistic alternative to school or university learning for people who cannot attend class.

There are also benefits to industry. In particular for Hong Kong, transmission of mixed text, pictures and data will be of extreme value to the many companies involved in publishing. Complete or partial magazines, books and so on can be produced in electronic format in one location and printed in another. This capability has revolutionised the newspaper industry in many parts of the world, most dramatically perhaps in the UK.

1325

Health care is another obvious and very important use.

One area of concern in Hong Kong is the shortage and high cost of providing medical facilities. The introduction of 'Enhanced Image Technology', similar to that offered by NYNEX in Boston, would help alleviate the problem.

At present there are, for example, a limited number of CAT scanners and MR imagers in Hong Kong, which are needed for diagnosing certain illnesses. This means that doctors have to travel across Hong Kong in order to be present when their patients require these facilities. Provision of high resolution medical imaging would mean that doctors could save time by having a display in their office and view results remotely. It would be possible for other specialists to give a second opinion without having to leave their own offices. In this way major hospitals can pool their facilities and share expensive and scarce medical expertise.

Conclusion

Today, digital switched video is not at the stage of development where it can supersede today's broadcast video systems. But in the not-so-distant future, advances in technologies combined with cost reduction in broadband switching, multiplexing and digital electronics will allow the evolution of an integrated network which can deliver digital video, voice and data to masses of customers.

We believe that consumers will be eager to embrace these new services and advanced technologies. The talents and energies of many businesses and organisations may be realised to their full potential by utilisation of these new services.

There is a well documented list of factors taken into account by multi-national organisations when they decide whether or not to set up a base in any given country. Well developed telecom is a priority factor on most lists. Not only good business telecom but

also residential. We are in a global market. Decision makers in major corporations because of different time zones frequently need to communicate with others from their home.

Once good telecom is available readily and economically at home they will soon be seen as essential Perhaps in a few years time more and more businessmen and women will operate from an office in their home.

Video encompasses all types of visual information which can be transported over a broadband fibre network. The use of fibre is a central ingredient in the evolutionary trend of a future switched video system. Whatever the future we plan to build a fibre network to keep Hong Kong as a leading world financial and trading centre into the next century.

At this time the opportunity for building and operating a second network is good, based on customer needs and the technologies available to meet them. A fibre network brought very close to the home, is the essential element in the broadband network of the future. From a Hong Kong perspective, the time is now to exploit this readily available technology to construct a superior network providing switched broadband services and maximise the tremendous opportunities that it will provide.

HDTV in Japan

1. History of the development of HDTV in Japan
2. Features of HDTV
3. Present state of HDTV technology
4. Establishment of HDTV standards
5. HDTV satellite broadcasting
6. Development of home use receivers
7. HDTV program production
8. Non-broadcast applications of HDTV
9. Exposure of HDTV to general public
10. Promotion activities of introduction of HDTV
11. Future of HDTV

History of the development of HDTV in Japan

1970: Development of experimental black & white camera
1972: Proposal to set up a new Study Program for HDTV to CCIR
1974: Development of experimental color camera
1975: Development of HLO-PAL transmission system
1978: Experimental satellite transmission of HDTV signals using 2 channels for luminance and chrominance signals
1981: Development of MUSE satellite broadcasting system
1985: Demonstration in Tsukuba Expo'85 including MUSE terrestrial transmission and 400-inch large screen projector
1986: Development of digital VTR
1986: First Experimental satellite transmission of MUSE signals
1987: Establishment of BTA studio standard (S-001)
1987: Development of HARP pich-up tube
1988: Development of UNIHI VCR
1988: International transmission of MUSE signals from Japan to Australia
1988: Transmission of Olympic games from Seoul, Korea to Japan
1989: Start of daily one-hour HDTV experimental satellite broadcasting
1990: Adoption of CCIR recommendation for studio standard
1990: Development of MUSE receivers using MUSE decoder LSIs chips
1991: Establishment of the standard for satellite broadcasting based on MUSE system

Feature of HDTV

1.	Wide aspect ratio	16:9
2.	Large screen	50-inch or larger in diagonal
3.	High resolution	Twice of standard TV in both vertical and horizontal directions (active 1035-line x 1920-sample)
4.	High quality color reproduction	
5.	Viewing distance	3 times of picture height
6.	Multi-channel audio	Rear 3 speakers Front 2 speakers
7.	Wide application capability for industrial uses	

1329

Present state of HDTV technology

1. Camera
   - High sensitivity HARP camera
   - CCD camera (2-million and1.3-million picture elements)
2. VTR
   - 1-inch open reel digital VTR
   - 1/2-inch cassette analog VTR
3. Switcher and special effect equipment
4. Standard converter
   - HDTV to NTSC
   - HDTV to PAL and SECAM
   - HDTV to Film
5. Transmission equipment
   - FPU (Field pick up unit)
   - Satellite transmission equipment
   - Digital transmission equipment
6. OB-van
7. Display
   - CRT display (32, 36 and 40-inch)
   - Rear projection display(50-inch ~)
   - Front projection display(100-inch ~)
   - Liquid crystal projection display
   - Plasma display(40-inch)
8. Broadcasting system
   - MUSE encoder
   - MUSE home receiver
   - MUSE home VCR and Disk
9. Other equipment and systems for industrial uses

1330

Establishment of HDTV broadcasting standards

1. Provisional studio standard used for Tsukuba Expo'85

   Scanning : 1125/60 and 5 t0 3 aspect ratio

2. BTA S-001 Standard

   Established by BTA (Broadcast Technology Association) in August 1987

   Scanning : 1125/60 and 16 to 9 aspect ratio

   Same parameter valuse with SMPTE 240M standard

3. National Standard for HDTV satellite Broadcasting

   Established in March 1991

   Based on the recommendations made by CCIR and the Telecommunication Technology Council (Japan)

   Studio standard : 1125/60 and 16 to 9 aspect ratio
   Emission standard : MUSE system

1331

HDTV Satellite Broadcasting

1. Daily 1-hour experimental broadcasting

(1) Operator : NHK

(2) Started in June 1989 using BS-3a

(3) Receiving site : more than 100 sites all over Japan

(Public spaces and department stores etc.)

2. Daily 8-hour test broadcasting

(1) Operator : Hivision Promotion Association
(Members : NHK and commercial broadcasters, production, manufacturers and others)

(2) Started on November 25, 1991

(3) One of three transponders of BS-3b is used exclusively for this broadcasting

(4) 4 hours are used for NHK programs and other 4 hours are used for programs produced by other broadcasters and program providers

Development of HDTV Receiver

1. Development of MUSE decoder using discrete-type ICs

(1) 11 manufactures developed MUSE decoders

(2) Started in April 1987 and finished in March 1990

2. Development of the first generation MUSE LSIs

(1) 6 manufacturers jointly worked with NHK for the development of MUSE LSIs

(2) 25 different type LSIs were developed in 1989

(3) MUSE decoders using LSIs were on the market in December 1990 and early 1991

3. Development of the second generation MUSE LSIs

(1) About 10 different kinds of highly integrated LSIs for a MUSE decoder

(2) Three different groups of manufacturers have been established for the development of 2nd generation LSIs

(3) Target date of the development is between 1992 and 1993

4. Consumer use VCR and Video Disk

(1) Several manufacturers agreed on the specification for HDTV VCR (Component signal type)

(2) Several manufacturers agreed on the specification for MUSE Laser Disk

HDTV Program Production

1. More than 600 programs have been produced using the 1125/60 system

2. Cost saving for the HDTV program production is essential

(1) International co-production of HDTV programs

(2) Use of HDTV programs for NTSC broadcasting

(3) Multi-media application of HDTV programs
Package, publication etc

Non-Broadcast Application of HDTV

1. Application areas

(1) Printing and publication

(2) Movie production

(3) Medical field

(4) Video theater

(5) Image processing

(6) Telecommunication

(7) Video data base

2. Estimation of market size of HDTV (by MPT and MITI in 1987)

Broadcasting : 3300 billion Yen (in the year 2000)

Indusrial use : 930 billion Yen (in the year 2000)

Exposure of HDTV to General Public

1. Objectives

(1) Better understanding of HDTV by general public

(2) Development of good and reliable equipment by manufacturers

2. Examples of large scale demonstration

(1) Tsukuba Science Expo'85 (1985)
MUSE terrestrial Broadcasting
400-inch large display theater

(2) Nara Silk-road Expo to Brisbane (Australia) Leisure Expo'88(1988)
3-hop transmission of HDTV signals using communications satellites(CS, Intelsat and Ausat)

(3) Seoul Olympic Games(1988)
HDTV satellite broadcasting of the opening and closing ceremonies of the Olympic Games(2-hop transmission)

(4) Osaka Flora Expo'90(1990)
Distribution of Expo HDTV programs to over 100 demonstration sites all over Japan

(5) Annual Hi-Vision Week(November 25 - 1125)
Special demonstration of HDTV

Promotion Activities of Introduction of HDTV

1. Hi-Vision City Project

(1) Project of the Ministry of Post and Telecommunication

(2) 24 cities have been appointed as Hi-Vision Cities

(3) Hi-Vison theater, Hi-Vision data base and Hi-Vision CAD/CAM will be introdused

2. Hi-Vision Community Project

(1) Project of the Ministry of International Trade and industries

(2) 19 cities have been appointed as Hi-Vision Communities

(3) Hi-Vision theater, Hi-Vision Art Museum and Hi-Vision data base

3. Hi-Vision Museum Project

(1) Project of the Autonomy Ministry

(2) More than 30 cities are appointed

(3) Hi-Vision Museum will be introdused using Hi-Vision still picture system recently standardized by HVC (Hi-Vision Promotion Center backed by MITI)

Future of HDTV

1. Digital HDTV broadcasting

(1) Analog HDTV Broadcasting (MUSE) using 12 GHz band

(2) Digital HDTV Broadcasting using 17~25 GHz band

(3) Integrated Service Digital Broadcasting
Family of services using 17~25GHz band, 12GHz and 1.5~2.5GHz bands

2. Stereoscopic (3D) broadcasting

(1) Much higher quality and reality than HDTV for picture and sound

(2) 3D display without using glasses

1335

Satellite Broadcasting in Japan

1. Present state of satellite broadcasting in Japan

2. Broadcasting service via communications satellites

3. Future of satellite broadcasting in Japan

1330

Present state of satellite Broadcasting in Japan

BS-3a

CH-7	Operator	: NHK
	System	: Digital Sub-carrier NTSC
	Service	: 24-hour
	Program	: World news and sports
CH-11	Operator	: NHK
	System	: Digital Sub-carrier NTSC
	Service	: 24-hour
	Program	: Entertainment and culture

BS-3b

CH-5	Operator	: JSB
	System	: Digital sub-carrier NTSC with scramble
	Service	: 24-hour
	Program	: Movie and entertainment
CH-9	Operator	: Hivision Promotion Association
	System	: HDTV (MUSE)
	Service	: 8-hour
	Program	: Entertainment, culture and sports

Future of Satellite Broadcasting Service in Japan

1. Schedule for launching of new satellites

(1) Broadcasting satellite

BS-4 (Post BS-3) (1997)

(2) Communications satellite

Super Bird-B	(Feb. 1992)
Super Bird-A	(Dec. 1992)
SJC-1	(Jun. 1994)
SJC-2	(Dec. 1994)
Post JCSAT	(1999)

(3) Experimental satellite for broadcasting and communication

COMETS	(1997)
COMETS-II	(1999)

2. New satellite broadcasting service

(1) Data broadcasting using digital data channel of NTSC satellite broadcasting (480Kb/s)

(2) ISDB (Integrated Service Digital Broadcasting)

- 17~25GHz band ISDN (~150Mb/s)
- 12GHz band ISDN (~40Mb/s)
- 1.5~2.5GHz band ISDN (~6Mb/s)
- Terrestrial UHF/VHF ISDN (~25Mb/s)

Broadcasting Service via Communications Satellite

1. Television service (Service to be started after April 1992)

(1) Super Bird B (To be launched in Feburary 1992)

- Nippon Cable Televisin
- Star Channel
- Music Television

(2) JC-SAT 2

- Space Shower
- Japan Sports Channel
- Eisei Eiga Engeki Housou

2. Digital sound service (Service to be started after April 1992)

(1) Super Bird B (To be launched in Feburary 1992)

- Space Sound Tokyo
- PCM Japan

(2) JC-SAT 2

- Satellite MUsic
- Music Bird
- PCM Zippang Communications
- Nippon Music Congress

BISDN STANDARDS IN THE US AND JAPAN

by
Dr. Hajime Oniki
Institute of Social and Economic Research
Osaka University
Ibaraki, Osaka, Japan 567
and
Prof. Terry Curtis
California State University, Chico
Chico, California 95929-0504

ABSTRACT: This paper investigates differences in the pursuit of BISDN standards in the United States and Japan. The hypothesis is that cultural and structural differences in the two nations have led to different assumptions and the setting of different priorities in the telecommunications standards arena. These differences at the national level result in difficulty at the international level as participants enter the international arena with differing conceptions of the values at stake.
KEYWORDS: BISDN; Telecommunication Standards; United States; Japan

Introduction

Critical political and structural differences exist between Japan and the U.S. with regards to their telecommunication industries. One area in which the differences have been quite marked is in the area of telecommunication standards. The processes by which telecommunication standards are agreed domestically -- and are pursued internationally -- in the two nations are quite different. These differences will be briefly reviewed here. The developments in BISDN standards will be used as an example.

The Setting of Japanese Telecommunication Standards

In the context of rapidly converging telecommunication and information technologies, the first key point to be made in describing the Japanese situation is that there is a division of responsibility between the MPT (Ministry of Posts and Telecommunication) and MITI (Ministry of International Trade and Industry). A gross simplification of the division is that MPT is responsible for telecommunication network standards and MITI is responsible for information systems equipment standards. On each side of this division the ministries are technically and officially responsible for the standards processes and publish the standards which are ultimately agreed. In each ministry the work of negotiating

[illegible] the output of these groups is advisory to the State Department and to its appointed delegations to the proceedings of the CCITT.

Because they cannot consider such matters as potentially conflictive with US national or international policy, national security, or enforcement for the US at international meetings, the US National CCITT Committee's conclusions are not binding on the delegations' discussions of contributions to the CCITT. Because of the emphasis on parallelism and participation in the US and because of the advisory nature of the US National CCITT Committee, normally the US CCITT Committee would wait for substantial agreement to have been achieved in TI before attempting to agree on a contribution to the CCITT. The proceedings of the TI Working Groups are considered the appropriate forum for the consideration of objections and for the debate over the wordings of documents. On the other hand, it is also normal for TI to work closely with the US CCITT Committee and to delay sending any draft standard to ANSI for recognition as an American National Standard until after the work of the CCITT on the issue. This delay is a recognition that deliberations at the CCITT, agreed to by the State Department's delegation, may substantially differ from the agreements reached at TI and may require reconsideration of the issue.

With regard to the division of authority over standards in the network and standards in the terminal equipment areas, there are other standards setting institutions in the US including the Institute of Electrical and Electronic Engineers and the Electronic Industry Association, among others. Unlike the Japanese case, however, there is considerable formal as well as informal liaison between the TI Working Groups and each of these other organizations in order to avoid duplication of effort and potential conflicts. Since all of this work falls in the private sector and largely concerns the code files, there is no comparable division of authority between ministerial bureaucrats, nor any justification for a failure to coordinate.

[illegible] BISDN STANDARDS

In using BISDN as an example of the differences in standards governance in the US and in Japan, the proper focus is on the way the two nations have reached domestic agreements and then have participated at the international level in the movement toward international standards. There have been a great many issues with regard to BISDN about which there have been differences along national lines. Two issues stand out as especially interesting:

a) SDH (SONET) frame format

system the structure not only allows but demands enormous input from a broad range of interested parties. But on the issues of a new technology like BISDN, one representative of one company can come to dominate the US contribution and the negotiation of the US position at the CCITT. Again, the causes of such a situation are both cultural and structural.

a) SDH (SONET) frame format

At the Hamburg meeting of Study Group XVIII in May of 1987, the US delegation tentatively gave up the US position of 13 rows of 180 octets and agreed to accept an SDH frame format of nine rows of 270 octets. Their position, however, was that they had no power to give up on the 13 row agreement which had come out of Committee T1, and would have to send the matter back to T1 for authorization. This frustrated the Japanese and European (especially British) delegations, which have the authority to negotiate for their countries. Two changes in the US participation at CCITT have since come about. First, T1 has begun to delay final consideration of any standard pending CCITT resolution. This recognizes the increasing importance of international standards to US manufacturers. Whereas at one time the US was a telecommunication island with little concern for global standardization, the market is now a global one and both US manufacturers and US carriers want global standards. In addition, US delegation meetings are held every morning at the CCITT and in some cases the attendance at these meetings includes virtually all of the interested and active members of the T1 working group responsible for the issue under consideration. This allows for some certainty that compromises negotiated at CCITT will be assured support at T1.

b) ATM payload type 2 - real time variable bit rate

NTT's view of the Japanese market for switched broadband services is heavily oriented towards video applications. Under the marketing label of Visual, Intelligent & Personal Services (VI&P), NTT plans a variety of services which will require the ATM type 2 - variable bit rate payload. For this reason, there has been considerable work at NTT on defining this transmission type. In the US, however, there are many competing visions of how video images can best be digitally coded and compressed for transmission. While some of the methods involve variable bit rates, many are continuous bit rate services. With little clarity on what will come out of the codec, there is little interest in the US on standardizing what will be carried through

STANDARD STRATEGIES - KEY TO PROFIT OR LOSS?

Joseph Onufrak
NYNEX, Telesector Resources Group
White Plains, New York, U.S.A.

1.0 ABSTRACT

This paper will discuss the strategic impact of standards development upon business success. The primary objective is to establish a linkage between evolving standards, the need for direct involvement, the resources, and the overall goals of the business. There will be several examples, and the paper will include information on the standards development organizations with an emphasis on telecommunications. The trend toward a global outlook in various standards development groups will be emphasized.

2.0 INTRODUCTION

Industry standards are the cornerstone for underlying technologies, networks, network elements, and services found in a companies network evolution or expansion plan. In the telecommunications industry, recent standards development trends in networking have facilitated the exchange of global information, and have improved the consistency of network interfaces. The overall impact has contributed to the communications infrastructure, and has been the basis for initiating global synergy between national communications networks. Examples of these trends are the evolution of international SONET standards, implementation of ISDN standards, the evolution to broadband ISDN, the worldwide development of Electronic Data Interchange standards, the developing standards for Universal Personal Telecommunications, and the Intelligent Network.

As detailed in subsequent sections, standards have a significant impact on a business entities ability to meet its strategic objectives. In addition, many of the services planned for introduction into communications networks will never work uniformly or on a national scale (or international scale) without the application of both national and/or international standards. It is therefore essential for business, at a time when globalization of the telecommunications market is taking place, to implement standards strategic plans based on corporate goals to assure the technical interoperability of a telecommunications network within local, national and international networks. Standards provide the foundation for confidence to network users and suppliers that all of the pieces needed to provide services will be compatible with each other's end-to-end network. Direct involvement in standards fora will enable economies in equipment acquisition operational costs, and significant opportunities in the offering of comparable services ubiquitously.

However, the key to using standards development as a strategic planning tool with an eye to improving the bottom line is direct participation in the development process. Unfortunately, very few if any businesses could reasonably afford the cost of broad base participation, specifically the cost of membership plus associated travel and the commitment of technical resources. In order to assure efficient use of technical experts to participate in standards development, the process should be managed to enable a select number of representatives to participate in key standards fora on a regular basis. These participants should be authorized to make standards development decisions, or agree to compromises at the working level. The representatives usually would be supported during the preparation of technical contributions by subject matter experts from a technical support organization (R&D; etc.). Planners, who could also be direct participants, should interact with R&D, manufacturing, and marketing to facilitate and ensure that the overall standards development is aligned with a common business goal.

3.0 OVERVIEW OF STANDARDS

The International Telecommunication Union (ITU), created in 1866 and now a specialized organization of the United Nations, is a key international organization for developing global agreements pertaining to the development of telecommunications standards. Per its charter, the purpose of the ITU is to maintain and extend international cooperation for the improvement and use of international telecommunications, and to promote the development of technical facilities with an emphasis on improving the efficiency, availability and effectiveness of telecommunications services, and to harmonize the actions of nations to achieve those results for the benefit of the general public. Membership in the ITU is by nation. Membership in the CCITT (International Consultative Committee on Telephone and Telegraph) and CCIR (International Consultative Committee on Radio) , the two technical organs of the ITU, is by Administrations, by Recognized Private Operating Agencies, and Scientific and Industrial Organizations. CCITT and CCIR are the key standards developing units within the ITU. CCITT develops recommendations for telecommunications. While countries are not legally bound by treaty to apply CCITT standards recommendations, they are encouraged to do so.

CCITT recommendations fall into two overall classes as follows: End-to-End standards, which cover the networks and the network terminals (not CPE), and both ends, and interface standards to enable customer premise terminals to interconnect into the regulated network. These recommendations have been published on a four year cycle and have been identified by the color of the binder. For example in 1984, the cover color was red, in 1988 blue, and in 1992 white. Beginning in 1993, recommendations will be published separately as soon as they are approved by the CCITT. United States participation is through the U.S. State Department via an organization officially designated the U.S. CCITT

(United States Organization for the International Telegraph and Telephone Consultative Committee). The public and private telecommunications sectors are encouraged by the State Department to meet and develop a United States position on all recommendations, and both sectors are further encouraged to participate directly in CCITT technical study groups (and related sub technical groups) to work on recommendations from the very beginning of the development process.

The U.S. standards telecommunications development process generally operates under the American National Standards Institute (ANSI) Guidelines, which require openness, balance, consensus, and due process in all phases of the standards development cycle. ANSI is a private, non-profit membership organization that coordinates the United States voluntary consensus standards system and approves American National Standards. It is also the U.S. representative and dues paying member of two non-treaty international standards organizations: the International Organization for Standardization (ISO) and the International Electrotechnical Committee (IEC) via the U.S. National Committee (USNC). ANSI membership consists of approximately 1,100 companies, 230 professional, technical, trade labor and consumer organizations, and 30 government agencies.

Prior to the divestiture agreement, which broke up the American Telephone and Telegraph Company (usually referred to as the Bell System), Bell System technical standards provided the specifications necessary for the national telephone network to operate in an integrated fashion. This effort was in cooperation with the United States Independent Telephone Association. One popular reference was entitled "Notes on the Network". (Note: A similar publication is currently published by Bellcore entitled, "BOC Notes on the LEC Networks-1990", Special Report SR-TSV-002275, Issue 1, March 1991.) With divestiture, there arose a need for an organization to carry out the network integration functions. The Exchange Carriers Association (ECSA) was established to promote the timely resolution of national and international issues involving telecommunications standards and the development of telecommunications operational guidelines. To accomplish this task ECSA sponsors the following committees:

- Standards Committee T1-Telecommunications: develops standards and technical reports related to interfaces for the United States telecommunications network, and develops positions related to telecommunications networks for presentation at international standards development fora.

- Carrier Liaison Committee: is an inter-industry organization, endorsed by the Federal Communications Commission, for discussion and voluntary resolution of nationwide concerns about the provisioning of exchange access service.

- Telecommunications Industry Forum: provides the guidelines for the electronic transfer of data over the network, and for the electronic transfer of telephone company customer billing based on Electronic Data Interchange (EDI) standards developed in ANSI Committee X12.

- Information Industry Liaison Committee: handles technical operational, and administrative issues associated with Open Network Architecture (ONA).

- Protection Engineers Group: provides for the discussion and development of standards contributions to ANSI accredited fora on electrical protection of exchange carrier facilities.

- Accredited Standards Committee 05: develops telecommunications standards for the telecommunications industry in technical areas dealing with wood poles and other wood products.

Committee T1 is accredited by ANSI and is the focal point for the development of telecommunications network interface standards. The work process is based upon ANSI Guidelines, specifically, on the ANSI "Style Manual for Preparation of Proposed American National Standards" and "The Procedures for the Development and Coordination of American National Standards". The objective is to publish standards with a broad consensus of support, usually unanimity. There are about 90 members in T1 representing Local Exchange Carriers, Inter-Exchange Carriers, Manufacturers (mostly U.S.), the U.S. government, Users of Telecommunications Services, and Others. Participation in standards development is open to anyone materially interested, and voting membership is easily obtainable by any interested service provider, manufacturer, user of services, or government agency, etc. Committee T1 is comprised of seven Technical Subcommittees (TSCs), which are further subdivided into working groups. These TSC working groups meet on a regular basis to develop standards that directly or indirectly affect communications networks. Because more manufacturers are developing equipment manufactured for global markets, cooperation and exchange of information between T1 and the CCITT has been the norm rather than the exception. In addition, there has been some limited cooperation between Committee T1 and the European Telecommunications Standards Institute (ETSI). Presently this work is being encouraged through regional meetings attended by Committee T1, CCITT, CCIR, ETSI and the Telecommunications Technology Council (TTC) of Japan. These meetings are known as the Interregional Telecommunications Standards Conferences. Key standards, which begin at CCITT, are often brought to T1 for comment or review to assure global compatibility. Conversely, T1 standards are submitted to CCITT as contributions via U.S. State Department Study Groups for the same reason. There are other organizations in the United States such as the Institute of Electrical and Electronic Engineers (IEEE), the Telecommunications Industry Association (TIA), the Corporation for Open Systems (COS), and the Cellular Telecommunications Industry Association (CTIA) to name a few, which also develop standards and contribute to the work of CCITT.

Another influential factor in the area of standards development both in the United States and internationally is the Bellcore Technical Analysis (TA)/Technical Requirement (TR) process. In practice, the TA/TRs and T1 standards feed into each other. Bellcore's TA/TR writers draw from both draft and finished standards. Often the TA/TR writers participate in the development of the standards. In general, the development of a TA/TR is faster and often helps to speed up standards

development. However, TA/TRs are technical analysis or requirements documents developed by Bellcore for the Bell Client Companies (regions) and do not have the industry and regulatory body acceptance of ANSI accredited industry standards. Often TA/TRs that have undergone industry scrutiny through the standards process become the basis for standards, which are often identical to the original TA/TR. A broad goal of Bellcore and the BCCs generally has been to work toward aligning TA/TRs with evolving standards.

Currently in the United States, there are telecommunications standards being developed for customer-to-network interfaces, network-to-network interfaces, services and architecture, switch to computer applications, intelligent networks, personal communications, network performance, network maintenance and many others.

4.0 BENEFITS OF STANDARDS

Standards serve the vital function of detailing the technical nature of telecommunications network interfaces and operations systems, thus ensuring proper interworking among the various elements of a modern network, including maintenance/operational systems. In addition, standards fora provide representatives unique opportunities to meet with other industry participants, gain insight into their telecommunications planning and obtain a level of both practical and technical network knowledge not available through any other industry association.

For a corporation, participation in the standards development process results in benefits as well as some risks. Examples of benefits are as follows:

- reduced equipment costs, by making network elements interchangeable and thereby inducing competition among vendors;
- vendor independence, by making equipment available from more than one vendor;
- economies of scale in the manufacturing and implementing of new network technologies, thus reducing costs and service providers rates;
- services and features transparency, thus ensuring that services will work the same way, regardless of the equipment used, or service provider;
- a source of competitive information;
- an enhanced corporate domestic and global image as a leader in telecommunication network development is acquired through visible and effective participation in standards fora;
- ensures that standards beneficial to corporations strategic business needs are developed through technical contributions, analysis of others' contributions, and efforts to develop industry consensus;
- provides a vital element for a companies Quality Program requirements for planning and implementing its future network architecture.

The risks are that standards could be adopted which are unfavorable to corporate business interests, that hamper the ability to meet the needs of customers or that delay the introduction of a service that has a finite market window. Obviously, all of these risks are associated with an economic penalty.

The key function of corporate standards strategic planners and representatives is to ensure that the standards developed are in harmony with network evolution and long term strategic business goals. Without effective participation and a strong voice, the other major industry players (who probably are competitors) may to a great degree determine how the telecommunications network will evolve, which may have a serious impact on overall competitiveness, the ability to increase revenues and conversely reduce operating and equipment costs.

4.1 Examples of standards activities in key technical areas

Below are *some* examples of standards issues related to Personal Communications Systems (PCS), Broadband Integrated Services Digital Network (B-ISDN), Switch-to-Computer Applications Interface (SCAI) and Universal Personal Telecommunications (UPT). These are presented here to provide the reader with an appreciation for the business implications resulting from the standards development process.

4.1.1 Personal Communications Systems

PCS are defined as systems that will provide a broad range of new communications services that will free individuals from the constraints of the wireline telephone network. With PCS, customers will be able to make or receive calls, regardless of physical location; home, office, train, etc., or another city/country.

The two major components necessary for full PCS are: (a) wireless access; and, (b) Intelligent Network (IN) functionalities. Wireless access will provide customers with a tetherless connection to the network enabling them to gain mobility. IN capabilities will provide networks with the intelligence to know where customers are located, how calls should be routed, whether customers attempting to initiate calls are authorized to do so, and how calls should be billed. With both components present, customers can initiate or receive calls anywhere in a home, office, train, plane, hotel, another city or another country.

PCS issues are being addressed by standards and/or regulatory bodies. Examples are as follows: new spectrum allocation, license eligibility, spectrum use, wireless access technology, and PCS numbering. Internationally, PCS standards are being developed in CCITT and CCIR under the designation Universal Personal Telecommunications (UPT) and Future Public Land Mobile Telecommunications Systems (FPLMTS). In the United States, PCS interface standards are being developed within Committee T1 with the cooperation of the Telephone Industry Association (TIA).

4.1.2 Broadband Integrated Services Digital Network (BISDN)

The U.S. standard for B-ISDN is being developed in Committee T1 technical subcommittees T1S1 and T1E1 and will be aligned with the standard being developed in the CCITT. This standard incorporates Asynchronous Transfer Mode (ATM) switching techniques and an ATM Adaptation Layer (AAL) for support services, which is connection oriented. The Institute of Electrical and Electronics Engineers (IEEE) 802.6 standards technical subcommittee on high speed connectionless data services approved a standard (December 1990) that defines a connectionless data transfer using a Distributed Queue Dual Bus (DQDB) interface for broadband services to be offered on Metropolitan Area Networks (MANs). This DQDB protocol forms the basis for an access protocol to a Switched Multimegabit Data Service (SMDS). The issue facing the standards bodies is one of compatibility, specifically between the IEEE 802.6 DQDB interface and the CCITT/T1 ATM/B-ISDN interface. Generally companies have encouraged the development of technical solutions to minimize the differences between the IEEE 802.6 DQDB interface and the CCITT/T1 B-ISDN/ATM interface to ensure a smooth migration to a B-ISDN network. This standards effort is being worked and probably has a high priority in company standards development strategy, in view of the evolution to a broadband network.

4.1.3 Switch-to-Computer Applications Interface (SCAI)

SCAI will provide the protocol and control mechanisms that will enable the definition and development of applications requiring the intelligent interaction between computers and either PBXs or central office switches. At issue in standards development fora, is the extent of alignment between a PBX computer and a central office computer interface.

SCAI has also been proposed as the application interface used to access the Service Node (SN), a subset of the Service Control Point. The SN is a network element identified in the Advanced Intelligent Network (AIN) Release 1 architecture. The SN may be used to provide advanced services. However, controversy surrounds the use of SCAI as the interface, and whether the SCAI standard will be completed in time for AIN Release 1, which is scheduled for deployment in the 1994-95 time frame.

Usually a regulated telecommunications standards planning strategy would support the development of a SCAI standard to provide a common platform for uniformly exchanging application process information between the telecommunications and data processing environments. Lack of a standard SCAI interface or other comparable interface could cause some customers of a telephone network services provider to request direct connectivity to a common signaling network, such as Signaling System Number 7 in the United States to access advanced call processing functions. SCAI provides access to these functions without the need for customer-to-SS7 direct connectivity. There is concern in some quarters that direct access to a network signaling system could cause network problems. (Note: In standards fora the rash of recent United States telephone network blackouts has resulted in considerable discussion on this question of direct access. Also of concern is the experience of data and computer systems and networks with virus infections, and unauthorized intrusion into communications networks and network elements.) The SCAI standard is being developed in the T1S1.1 working group (Architecture and Services). The group's objective is to define a method for uniformly exchanging application process information between the telecommunications and data processing environments.

4.1.4 Universal Personal Telecommunications Numbering

The broad goal of Universal Personal Telecommunications (UPT) standards development is to provide for communications services to (and from) a person rather than to (and from) a specific location, thus stretching personal mobility as well as terminal mobility. The transmission path used to transport this service may use wireless technology or wired technology and may be regulated or unregulated. As a result, a unique personal address (number) identifying a person rather than a location with an associated data base is desired. At issue, is the standard structure of the address, its relationship to the service provider's network, and the administration of the number data base. Other issues concern portability of numbers, simplicity, and the evolution to a personal number not based on geography.

The numbering question is being discussed in CCITT Study Group II. One camp feels that the present numbering arrangements are adequate. Another proposal is for a plan based on using a prefix of up to three digits prior to a personal number to identify a UPT call. At issue is the economic penalty which will probably be incurred by the operators of telephone networks to handle the potential of a longer address to terminate a call, and its subsequent effect on a future intelligent network data base.

5.0 CONCLUSIONS

In order for a business entity to be effective in ensuring that evolving standards are consistent with strategic network plans, it must be prepared to commit the technical and planning resources required to support strategic network business goals in an ever-accelerating development of software and protocol related services. The number of services that require standardized protocol and procedures is a direct function of the explosive growth in computer processing power and the growing use of computer to computer communications. The massive increase in microprocessor capacity and throughput is fundamentally changing the nature of the telecommunications business; the focus is now on software design and protocol development. The demand this places on standards resources is clear. To position standards to assure effective implementation of company network modernization strategies will require a managed commitment to the standards planning and development process, by participating in those standards fora that will most benefit business goals, while making efficient use of usually scarce technical resources.

Standards are critical to sustaining a robust information industry and a nation's communications infrastructure. Companies that participant in the information industry usually do or will compete throughout the world. However, it is probably impossible for the United States information industry or some other nation's information industry to succeed in a global competitive market without a robust modern communications infrastructure. There is no doubt that evolving standards in both domestic and international fora will determine to a great extent the communications infrastructure. The effective way to ensure that communications standards will not result in an economic penalty is to influence standards development through an active participation plan in key technologies based on a business strategy related to specific business goals. The alternative is to react to the influence of others. Usually these others may be your competitors in the global (or local) market.

6.0 Acknowledgements

Mr. Woody Saleh, Staff Director at NYNEX, was a great help in sorting out the international view of standards. Mr. Saleh and Mr. Victor Acosta (also a Staff Director at NYNEX) offered suggestions concerning examples and patiently read and re-read the manuscript. I thank them both for their valuable help.

WIRELESS EVOLUTION
NEW CHOICES FOR ASIA PACIFIC

by

Rafael A. Sanabria and Ken Blakeslee
Northern Telecom Wireless Systems
Richardson, Texas, U.S.A.
&
Maidenhead, England, U.K.

When it comes to the evolution of personal communications, the wireless options associated with cellular and other transmission methods provide Asia Pacific with a unique advantage.

The rapid advances in mobile telecommunications technology taking place in other parts of the world are too often slowed, if not actually hampered, by the need to take existing infrastructures and regulatory requirements into account. Asia, on the other hand, has the advantage of being able to select the most appropriate communications technology and protocol from any source. (See Figure 1).

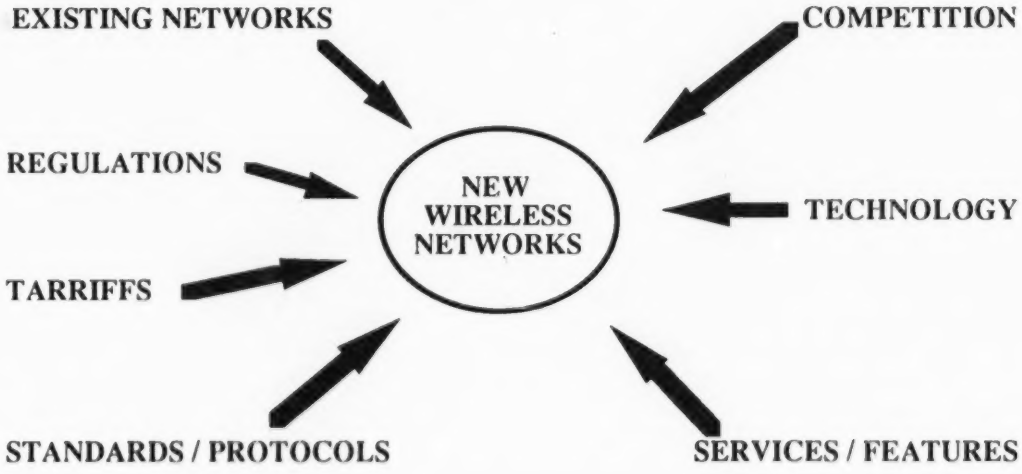

Figure 1. - Influencing Factors

Where necessary, this choice could mean a mixture of protocols and standards, subject to careful planning and a prudent assessment of the functionality to be deployed. As a pointer to the choices likely to face potential user countries, it is useful to examine how mobile communications is evolving in the US, Europe, and Japan.

In the US, despite the difficulties associated with analog cellular, the single AMPS (Advanced Mobile Phone System) analog standard has allowed cross-country uniformity

of systems which has brought associated cost benefits. Unfortunately, as subscriber demand has increased, so has pressure on the radio frequency spectrum.

This pressure is causing a split in the approach taken to solving a developing spectrum capacity problem. Different localized digital solutions are being proposed in an attempt to balance network capacity requirements with allocated spectrum. Several radio standards have emerged and the 1990's see several major divergent solutions competing for market share. (See Figure 2).

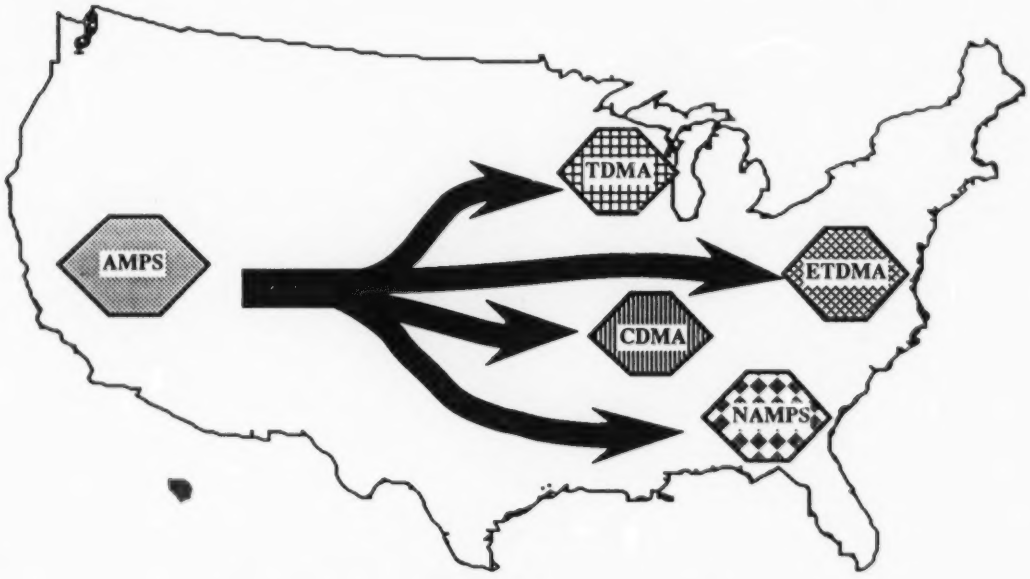

Figure 2. - US Standards/Protocols

Each is hailed as the solution to the efficient division of the radio frequency spectrum, each dominant in its own specific areas: NAMPS (Narrow band AMPS), CDMA (Code Division Multiple Access), TDMA (Time Division Multiple Access), ETDMA (Extended TDMA), etc. The result is a patchwork of mobile communications systems, each one incompatible, or compatible at only a basic level, with another.

Subscribers to these incompatible solutions are limited to their area of coverage despite the localized spectrum efficiency on offer. In the US, these digital technologies are, in effect, only access methods laid over the analog AMPS network. Roaming beyond the initial area requires commercial agreements between companies, but more important, handsets may be incompatible across subscriber regions which use alternate protocols. The economies of scale associated with a widespread, homogeneous infrastructure, and which bring lower cost handsets and services to market, may now be more difficult for operators to

achieve in the US. Several field trials are ongoing in the US at this time to prove out the merits of each technology.

In contrast, the evolution of cellular systems across Europe and Japan, although initially fragmented, has taken an interesting turn towards homogeneity that can yield useful lessons.

In Europe, the analog TACS (Total Access Cellular System), an outgrowth and improvement on AMPS, and NMT (Nordic Mobile Telephone System), was soon followed by an extended version, ETACS, joining Radiocom 2000 (France), CNetz (Germany), and versions of NMT in a complex pattern of incompatible systems across Europe. The now familiar patchwork effect has become apparent on an international scale. (See Figure 3).

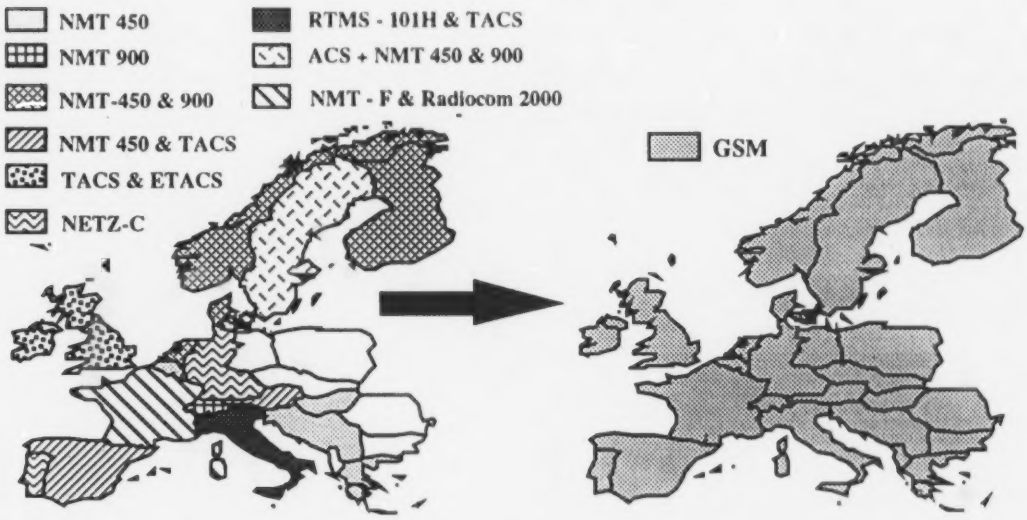

Figure 3. - European Standards/Protocols

Europe, however, has made moves to standardize on a new digital system to harmonize and provide mobility to the European Economic Community (EEC) as a whole. This system, which has evolved to be known as GSM (Global System for Mobility) has also realized the attention of many non-European countries, including several in the Pacific Basin.

In addition to full support from the 12 EEC members, GSM is being considered, or has also been chosen, as the future basis of digital cellular and Intelligent Network services by Australia, New Zealand, Singapore, Hong Kong and several countries in the Middle East, Eastern Europe and non-EEC countries.

Europe's approach to the capacity problem has been to allocate frequencies in the 900 MHz and

1800 MHz bands to accommodate the deployment of the new generation of GSM digital wireless systems.

Approximately 25 MHz of spectrum has been completely cleared across all of Europe at the 900 MHz band, and 75 MHz at the 1800 MHz band has also been cleared in several countries where capacity problems are expected (e.g. UK, Germany), and has been reserved in most other EEC countries. The 1800 MHz band, combined with the micro cell structure, will provide the extra capacity to deliver mobile cellular services to the population at large.

The global interest in GSM is partly due to the major effort being made in defining the infrastructure equipment and systems. Trial systems are already deployed, and commercial service is expected in several countries by mid-1992. Unlike cordless standards such as CT1(Cordless Telephone 1st Generation), CT2 (Cordless Telephone 2nd Generation), CT2+ (Cordless Telephone 2nd Generation Enhanced), and DECT (Digital European Cordless Telephone) and radio standards such as CDMA, TDMA, etc, GSM comprises a total open network specification, covering both radio and network interfaces and building blocks. (See Figure 4).

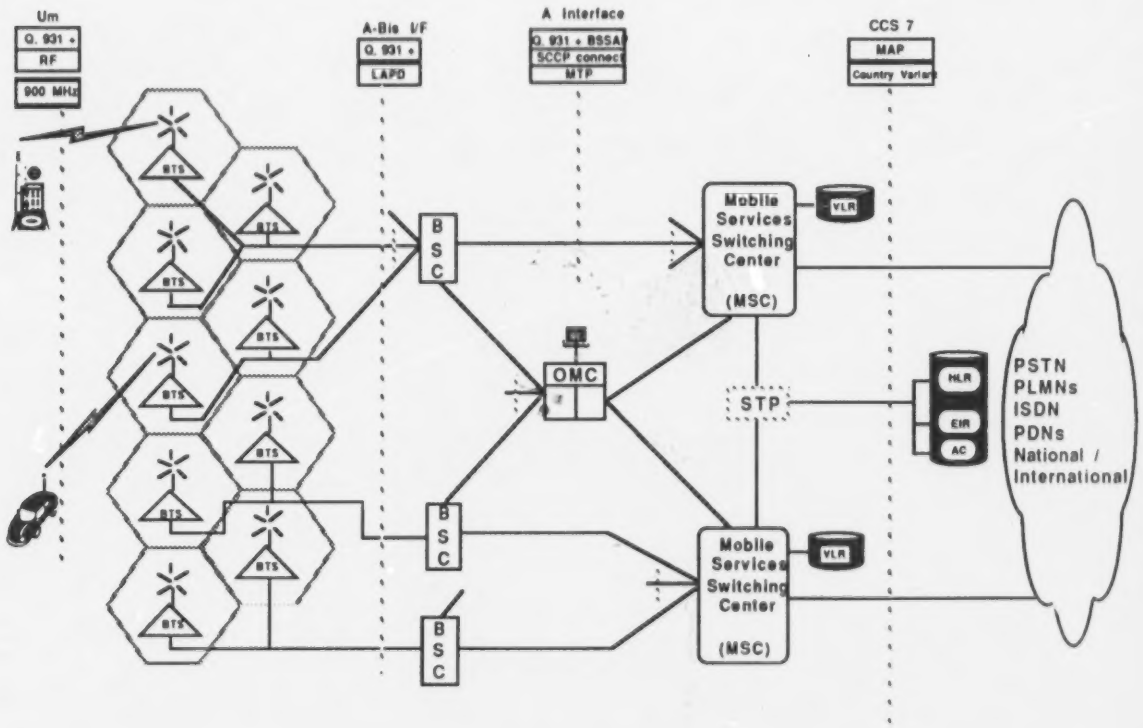

Figure 4. - GSM Model

The GSM standard is comprehensive, from the central billing and administration processing to handsets. It offers pan-European (and worldwide) roaming, high security, quality, and capacity. GSM offers the improved clarity associated with digital transmission, plus far greater reliability and consistency compared with analog cellular. Data services, being inherent, are faster and more reliable, obviating the need for modems.

The mobile network, with the GSM standard at its heart, can be a natural architectural and services extension of the fixed Intelligent Network, combining the traffic load of fixed and mobile subscribers on the same Intelligent Switch. It is both ISDN (Integrated Services Digital Network) compatible and AIN (Advanced Intelligent Network) friendly. A true "Intelligent" PCN (Personal Communications Network) could therefore evolve either from a mobile or a fixed network operation. (See Figure 5).

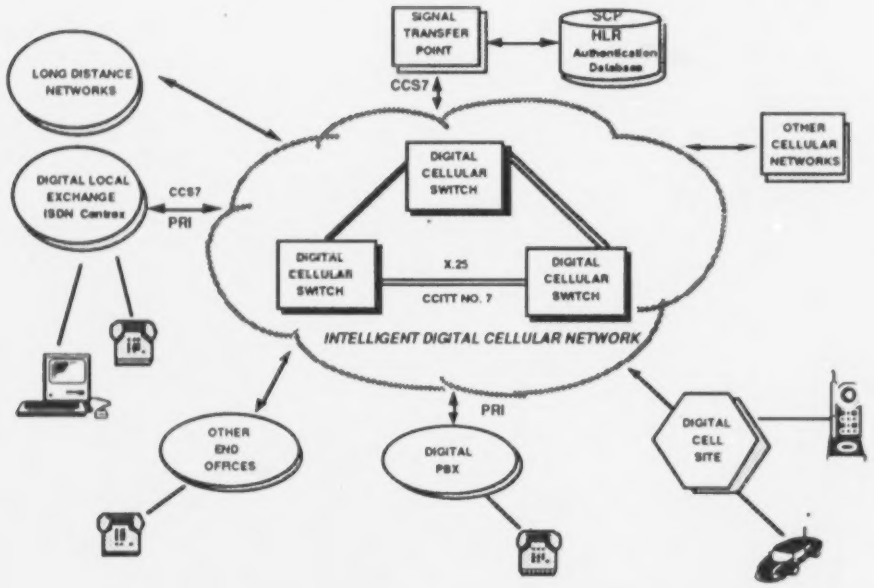

Figure 5. - Mobile Intelligent Network

In Japan, as in Europe, the evolution is also to a single digital standard, JDC (Japan Digital Cellular). (See Figure 6). It combines most network and functional characteristics of GSM (See Figure 4 - GSM Model), including ISDN/AIN capabilities and network architecture, with US-TDMA air interface type of protocols.

Other mobile techniques used in several markets, while appropriate in the absence of anything better, have similar limiting factors for a user base with growing expectations. Private Mobile Radio, for instance, provides effective coverage, but over a limited area. It is a closed system, with limited

capacity and lacks the signalling sophistication to interface to public or private voice/data systems.

The new wireless ISDN/AIN functionality and interface protocols will allow the deployment of enhanced revenue producing wireless features and services in the 1990's.

For their part, the 1980's will be remembered as the decade in which mobile communications flourished primarily through the introduction of cellular communications. The main emphasis of existing services deployment has been to provide extended coverage and network capacity. The 1990's will be characterized by quality enhancement and the availability of wireless communications features/services to the population at large.

Figure 6. - Japan Standards/Protocols

To date, users have for the most part been business and "status" subscribers. They have accepted high operating costs and inconsistent quality for the ability to make and receive calls away from the desktop or payphone. Network rollout timescales differ from country to country, as do expectations of the level of available services, but the growth of mobile communications continues unabated and at an unprecedented level.

Infrastructure and technological improvements in a free regulatory environment are only part of the solution; users must be given the right combination of services in a simple, controllable form to meet their individual needs. Services analogous to the PSTN (Public

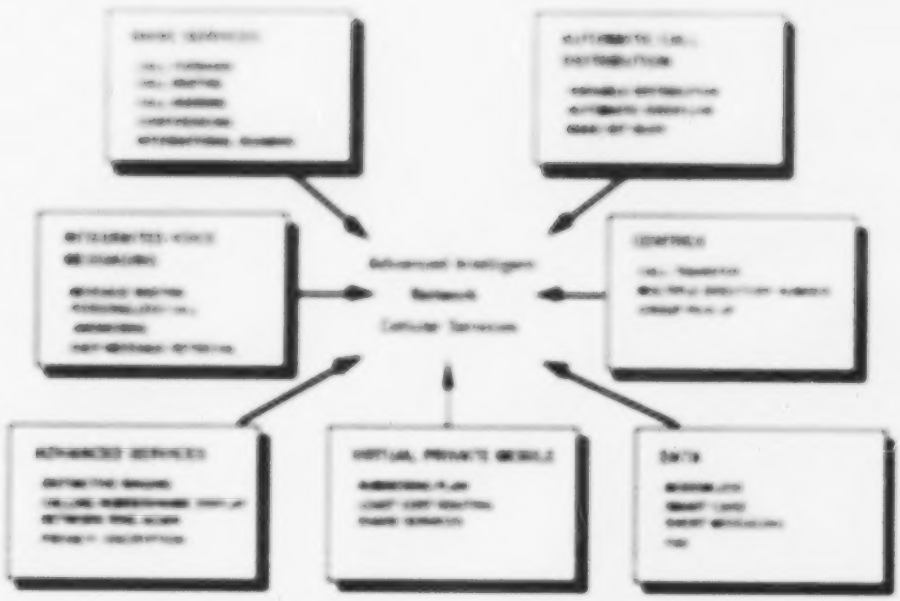

Figure 7. - Advanced Intelligent Network Cellular Services

Tariffs for local calls versus those for long-distance dialing are set to become a serious differentiator between service providers. The mobile network architecture should enable business services associated with centralized PBX's, such as call screening, call barring and least-cost routing, to be offered as part of the mobile package, with the same reliability as its fixed counterpart.

As a result, mobile services would then prove to be attractive to large corporate users, but in comparison with the conventional telephony, they will also be cost-effective for smaller organizations and, eventually, one-person businesses on the strength of extended functionality and mobility.

The attraction for countries already committed to ISDN based protocols, like GSM, is the ability to offer a mass-market service, rich in functionality, but recognizing that cost-effectiveness and control is critical. Corporate communications managers will only be interested in offering GSM handsets en-masse if the mobile network costs can be monitored and controlled to the same level as their fixed network. (See Figure 7)

Network operators can extend the control mechanisms inherent within the GSM specification to offer competitive accounting and billing services, such as selective barring, as well as value-added services. For their part, network providers have the challenge of delivering robust, high-capacity digital networks, including the AIN interfaces, across Europe and elsewhere.

Today, several digital technologies are being deployed throughout the world, catering to specific wireless applications, including cordless standards (CT2, DECT, etc.) and the new digital cellular standards including JDC, TDMA, CDMA and GSM, depending on the specific needs of each market.

Unlike the others, which are primarily air interface specifications, GSM and JDC represent a total network architecture consistent with AIN and ISDN, and therefore potentially compatible with the Fixed Network from a services ubiquity standpoint.

Learning from the pioneering work in the US, Europe and Japan, Asia Pacific countries can select viable and flexible architectures, able to deliver the right capacity and subscriber feature set to meet local and international user demand in an increasingly competitive world market. (See Table 1).

	AMPS	NAMPS	TACS	TDMA	CDMA	GSM/ PCN	JDC	CT2
Multi Market Acceptance	High	Low	Med	?	?	High	Low	Med
Enhanced Services (ISDN)	Low	Low	Low	Med	Med	High	High	Low
Quality	Med	Low	Med	High	High	High	High	High
Full Area Coverage	Yes	Yes	Yes	Yes	Yes	Yes	Yes	No

Table 1. - Systems Characteristics

Exactly how the rollout of communications services, both fixed and mobile, corporate and personal, will occur is still uncertain. How well and how fast subscribers will embrace the new, enhanced

services and their global capability has yet to be tested. Which standards will prevail is also unclear, but will no doubt depend on regional initiatives and on the market drivers in individual countries.

The explosive growth of the 1980's showed that in spite of capacity problems, question marks over quality, limited services, high costs and the variety of standards, mobile communications is already destined to capture a very large number of users. It alone provides the freedom, flexibility and security in communications sought by the potentially huge mass subscriber population. What remains to be seen is the relative success of the various standards, and how ubiquitously these Mobility based networks will operate with existing and developing public and private fixed networks.

Biographical Details:

Rafael A. Sanabria graduated from the University of Illinois with a Bachelor of Science Degree in Electrical Engineering and holds 3 patents on switching systems. He is currently Director of Marketing for International Cellular Networks at Northern Telecom in Richardson, Texas, U. S. A. In this capacity, he is responsible for the World wide marketing activities of Northern Telecom's cellular products. In his previous assignments, he has been responsible for network consulting, design, and engineering of over 30 public and private networks both in the U.S. and global markets. He has also been responsible for the design and development of various switching systems, and for the coordination of World wide bidding strategy and activities for applications in public, private, and military networks. Past employers include ITT in Great Britain and Belgium and GTE in the U.S.A.

Ken Blakeslee is currently Director of Market Development for Cellular Networks with Northern Telecom Europe, headquartered in Maidenhead, England. Ken has spent the past 8 years in the UK focusing on the marketing aspects of introducing advanced telecommunications services into the European fixed, and more recently the mobile subscriber environment.

ASEAN AND WORLD TELECOMMUNICATION DEVELOPMENT

Tjahjono Soerjodibroto
PT Indosat
Jakarta, Indonesia

ABSTRACT

The world experienced global movement of capital, technology, goods and services, and people. This movements stressed the needs of three basic infrastructures, transportation, energy and telecommunication. The world competition will be on the area of trades, tourism, and with more concern on environment. This signifies the role of telecommunication as key infrastructure to achieve country and company competitive advantages.

ASEAN as a form of cooperation has put telecommunication as the area where strategic cooperation and alliance is the most important to balance the difference economic development achievement in its member countries.

In this relation, the ASEAN governments welcome the participation of foreign and private entities to invest in each ASEAN countries. The governments aware that they need to provide better climate for investments, trades and tourism. It is the reasons that economy deregulation and other policies to support the new and attractive climate were introduced.

1. INTRODUCTION

The evolving Pacific Rim economy is one in which economic and social relations among its members are rapidly intensifying. This intensification of relations is occurring as a result of greater flows of capital, technology, goods, services, and people between the west and east coasts and the northern and southern countries of the Asia-Pacific region. The capital movements include loans and aid, as well as portfolio and direct investments. The people movements include salesmen, workers, tourists, managers, students and immigrants. All of these flows increase the interpersonal contact between the Pacific Rim nations in a variety of overlapping roles as competitors, customers, suppliers, partners, classmates, and neighbors. The increasing interpersonal relation between and inside nations requires the existence of telecommunication facilities in the Pacific Rim region.

As we enter the twenty-first century the world situation is changing quite rapidly. The world economy has entered the globalization era. A number of trends that gathered strength in the late 1980s will shape the international economic environment of the 1990s. Seven of these, which will shape the patterns of relationships in the Asia-Pacific region can be formulated as follows:

a. the evolution of U.S.-Soviet relations from conflict to cooperation,

b. the collapse of communism in the Soviet Union and eastern Europe,

c. the reversal of U.S.' locomotive role in world economy,

d. the ascendancy of Japan as the world's banker,

e. the economic integration of western Europe,

f. the economic integration of north America, and

g. the emergence of China as world potential market

All of these ongoing changes are likely to combine to strengthen economic integration in the Asia-Pacific region.

The development of economic in the Asia-Pacific region requires the availability of three infrastructures, transportation, energy and telecommunication. These infrastructures are required to support the development in the Asia-Pacific nations. The availability of the three infra structure will secure any capital investment inflow to the developing Asia-Pacific nations. The needs of telecommunication infrastructure to guarantee the success of any capital investment is very obvious. The relocation of developed countries industrial estates to the developing countries will require a high quality and reliable telecommunication for control and transfer of information between the new industrial location and the head office. The unavailability of such facilities will certainly disturb the fast inflow of the capital investment to the developing countries in the Asia-Pacific region.

Compare to other region in the world, The Asia-Pacific region is the fastest growing economic region. It currently produces nearly half of the world's GNP and has more than one third of world trade. With a population of nearly two billion and economy growth rate of 5% per year for the last ten years, the Asia-Pacific region certainly has the potential to become an attractive market for consumer products and industrial estate in the next century. And as what other parts of the world experienced, Asia-Pacific is also experiencing the world competition on trade and tourism coupled with a high concern on environment. In this competitive era, telecommunication networks assume strategic dimensions for companies and countries who want to stay competitive in the 1990s. Many countries and companies have realized that to stay competi-

tive, they need information. To them information is the key to success. And there will be no information if there is no telecommunication networks. That statement is just to express the paramount need of telecommunication infrastructure in the new and modern business world. As Jan Bartkowiak of Interprego said that without telecommunication there will be no information, and without information you can compete. To the business environment telecommunication network is like the blood circulation in the body. Even the World Bank has stated that the world economy is increasingly becoming one base on the free and continuous flow of information.

2. INDONESIA'S ECONOMIC GROWTH

The enormous economic growth rate in the Asia-Pacific region also experienced by Indonesia. Futurists forecasted that the Indonesia's economic will grow high and steady. Contribution to country's economic growth is expected to come through the growth in non-oil export, foreign investment, tourism, and other domestic industries. Indonesia also need the three basic infrastructures to provide the favorable climate for foreign capital investment. The Indonesian government has stated that one of the essential ingredient needed to support the development of national economic activities is telecommunication. Good and reliable telecommunication facilities is very important in enhancing the international and national trade activities, supporting banking activities, increasing tourists inflow, new investments, and industry expansion.

The Indonesian economy in 1990 grew at a relatively rapid rate of 7.4%, down slightly from the 7.5% rate posted in 1989. Though the growth rate of the agricultural and mining sectors were below previous levels, the gross domestic product was still high due to the 12.3% growth rate posted by the manufacturing and construction sectors. From the National Investment Coordination Board's data, private sector investment on the manufacturing areas have shown a high and rapid growth. In 1990 itself, the manufacturing sector accounted for nearly 25% of the gross domestic product and was the source of 30.8 % of its increase. Indonesian gross domestic product has risen steadily from 85 trillion rupiah in 1985 to estimated 122.7 trillion rupiah in 1991 (center for policy studies' sources).

The Indonesian gross domestic product growth rate steadily increasing every year, from 5.5%, 5.9%, 4.9%, 5.8%, 7.5%, 7.4% and 6.3% for 1985, 1986, 1987, 1988, 1989, 1990 and 1991 respectively. Form the collected data, the Indonesian economy had begun to show some slow down starting from mid-1990 due to high inflation rate, the slow growth of export resulting from the international recession situation, tight monetary policy adopted by the Government to encounter the national high inflation rate and consumerism in Indonesian people daily life, and limited economy infrastructure facilities.

The sectoral composition of the Indonesian economy is shifting toward a balance between the primary sectors (agricultural and mining) and secondary sectors (industry and construction). For the first time in 1990, the share of industry and construction sectors to national the gross domestic product has surpassed the agricultural and mining sectors. The country also experienced an increase in the volume of imports of capital good and raw materials and falling prices for its primary commodities in the international markets.

Government investment is still the largest contributor to the growth of the national gross domestic product. With the constraint experienced by the Government to mobilized national funds, the Indonesian government is currently looking to find new sources for its national development programs. This policy stressed on mobilization of private and foreign investment programs by way of improving the investment climate in Indonesia. Improvement of the investment climate in Indonesia is done by way of national economic deregulation, loosening the tight investment procedures, and the most important action is to provide better national infrastructure in transportation, energy and telecommunication.

It is also important to note that in Indonesia presently experience a structural transformation process on its industrial system, as well as the change of social life value as a result of industrial revolution. The structural transformation process characterized by the direct link age of services requires by the industrialization process, such as transportation, energy and telecommunication infrastructures.

(ASIA WEEK APR.91)

From table 1 above, it shows that among the six ASEAN Countries, Indonesia is the most populous country with the lowest GDP per capita and the lowest number of line units per one hundred population. Therefore it is understandable why the Indonesian government is very aggressive in constructing telecommunication facilities in Indonesia.

Due to limited funds available, the government now is stressing on mobilization of private and foreign investment programs by way of the improving the investment climate in Indonesia. Some deregulations to promote private and foreign investment have been implemented. The government loosen the investment procedures but, that was not enough without improvement in the basic infrastructures such as transportations, energy and telecommunications. The government put these three in its priority list and opened up private participation whenever necessary and applicable such as the built, operate, and transfer (BOT) scheme in power plants, telecommunication, as well as in sea-port development.

In telecommunications, Indonesia has been left behind compared to other ASEAN countries. The telephone density in Indonesia is only 0.52 line units per 100 population (1990), while Singapore has reached 43, Malaysia 9, Brunei 16, Thailand 1.9, and the Philippines 1.5. We have to break and eliminate this bottle-neck caused by the telecommunication infrastructure. Some measures have been taken to speed up the progress of expanding the national telephone capacity in terms of the number of line units.

3. INDONESIA TELECOMMUNICATION SITUATION

Telecommunication facilities in Indonesia is handled by the Government. In daily operational activities, the Government run telecommunication services through its companies. PT TELKOM is designated as the domestic telecommunication carrier, as well as the operator of the country domestic satellite system, PALAPA. PT INDOSAT is designated as the international telecommunication carrier for Indonesia. It owned various submarine cable systems and operates INTELSAT satellite system in Indonesia. Both companies is owned by the Government.

As mentioned above, capital investments in one country need good national transportation, energy and telecommunication infrastructures. The increasing capital investment in Indonesia requires improvements in the national infrastructures.

Telecommunication is one of the important national infrastructure. The existence of a good telecommunication system in one country will increase the country's comparative advantage in attracting capital investment. This situation is in-line with the industrial relocations to the developing country. Economic globalization also stresses the requirement of telecommunication facilities to smoothen the relationship between the manufacturing and the head offices. Therefore the Indonesian government adopted policies which are implemented through its national telecommunication companies, that can be summarized into providing the best services to the customers, while achieving the best result for the shareholders and establishing the best corporate image for the telecommunication entities.

By end of 1991, the number of the national telephone lines is about 1.4 million line units. Comparing the existing telephone lines with the present demand, approximately there is a shortage of 1 million line units. The present telephone density is 0.64 for 100 population or less than 1%. This put Indonesia at the lower group in the provision of telecommunication facilities. Among the ASEAN countries, Indonesia is the lowest country in the national telecommunication provision and quality of service as well. Government and its telecommunication entities still have a lot things to do to improve the telephone density, and its quality of service.

Since 1988, the telephone line units average growth rate stays at 27.6% per annum, but the demand for telephone lines increases much more rapidly. Therefore it is very difficult to meet the demand with the present telephone line units construction capacity. With hardwork, the country has successfully increased the annual telephone lines construction capacity to almost six times, giving a total of 240.000 line units per year. Gradually the country will put effort to increase its development capacity into an average of one million lines per year in the 1994-1999 era.

Telecommunication infrastructure improvement is done not only in terms of adding and distributing more telephone line units. To become attractive for foreign involvement, Indonesia should also considered improvement in the types of services. In the global competition era, we cannot wait for information. Plain Old Telephone Service (POTS) is not enough. Various new advanced services, especially for high speed data communication are becoming more in demand.

On the other hand the fund available is limited, but the new Indonesian Telecommunication Law No. 3/89 still restrict any means for privatization in basic telecommunication. This policy was taken due to a certain condition that the government has to protect the public interest, especially people in remote areas. The need for development in remote areas may not be justified from just the business returns point of view if it is taken by private organization (some subsidy will be required).

The effort to accelerate telephone lines construction is not only facing threat from the

shortage of funds, but it is also facing the shortage of manpower, not just for construction and project management, but also for operation and maintenance. The number of telephone lines increases from 1.4 millions in 1991 to approximately 7 millions by 1999, reflecting a five times multiplication on the numbers of lines. This will also be reflected in the approximately same number of multiplication in the manpower required for the operation and maintenance. The Indonesian government is very well aware and concerned with this limited funds and manpower availability.

Other problem that the country faced in constructing the telecommunication infrastructure is the distribution of telecommunication facilities in Indonesia. This distribution of telecommunication facilities has a tight relationship with the economic activities in the country. Presently the concentration of economic activities in Indonesia is in the Western part of the country. This resulted in the telecommunication production in Western part of Indonesia being much more promising compared to telecommunication production in Eastern part of Indonesia. Furthermore this situation brought a dilemma to the telecommunication entities. As profit-oriented companies they have to maximize any opportunities to make profits, but as government-owned companies they have to support the government's programs to improve the quality of life of the Indonesian people through the development of telecommunication infrastructure in Indonesia. This second mission of the telecommunication company in Indonesia in reality will decrease the possibility to collect community funds needed for the construction of telephone infrastructure in Indonesia. While if the government decides not to construct the telecommunication facilities in the eastern part of Indonesia, it will slow down the national economic development in the eastern part of Indonesia, which at the end will have an impact to the overall economic development in Indonesia.

With this condition, environment and requirement specific to Indonesia, we then question the need for Indonesia to follow the world trend in deregulation and liberalization of telecommunication services. But we can understand the different objectives and approaches taken by other countries who have implemented their de-regulation, liberalization, or privatization. Indonesia is in full support to the policies that have been taken in other countries.

Indonesia took a different approach in deregulation through the new Telecommunication Law No. 3/89. In this law, all basic services should be handled by state owned operators, while non-basic services can be operated by anybody with government approvals and controls. Government encourages private participation in developing the non-basic services. While in the basic services the private sectors can participate with the cooperation and on behalf of state owned operators. The latter became important issues when the government introduces private participation in developing and operating local telephone exchanges through revenue sharing scheme (BOT). With this policy the government is hoping to be able to construct one million additional new line units every year for the next five years plan, which will bring Indonesia to the level of telephone density of 2.7 line units per 100 population.

4. INDOSAT'S CONTRIBUTION TOWARD THE INDONESIAN TELECOMMUNICATION INFRASTRUCTURE DEVELOPMENT

As the trend of economic globalization grows, telecommunication becomes a vital factor in creating the comparative advantage of any company in the competitive environment. Countries and individuals need to exchange information, in the form of texts, voices, or pictures. These information will be used for decision makings, negotiations, or promotional purposes. The national economic activities requires the support of telecommunication services. It is interesting to note that as the international telephone traffic growth, it grows in the same direction as the gross domestic product, import-export activities, foreign investments, and tourism activities.

For its customers, PT INDOSAT always try to improve its services. As the demand for the types of international services become more complex, PT INDOSAT has an obligation to provide the necessary services required by its customers. Following this policy, PT INDOSAT introduces new services to cater the need of a more modernized and global customers, with the understanding that this new services are required not only to maintain its customers and provide a good and reliable services, but also to eliminate the possibility of customers to turn off and find a more desirable service substitution. Some of the new services are Intelsat Business Services, International Direct Dialing, Home Country Direct, Electronic Mail Services, Voice Mail Box, and Store and Forward Fax. In general what PT INDOSAT has done is keeping up with the technology development through the introduction of new services, new technology implementation, promotion of information technology, and improvement and development of the international telecommunication facilities, such as switching, satellite and fiber optic submarine cable.

The need of better telecommunication infrastructure in Indonesia forced the government to utilize all of its owned resources. Mobilization of funds, manpower and other things on a nationwide scale is carried out by the government. The responsibility of improving the development of national telecommunication infrastructure is not the sole responsibility of PT TELKOM as the national domestic telecommunication carrier, but it also the responsibility of the Indonesian telecommunication community.

PT INDOSAT being one of the important player in the Indonesian telecommunication community has a morale obligation to support the government programs in improving the national telecommunication infrastructure. To implement this morale obligation, PT INDOSAT launched the national telephone development program called JOINT COOPERATION PROJECTS for national telecommunication facilities. In this scheme, PT INDOSAT as the country international telecommunication carrier, functions as the assistance to PT TELKOM's projects of national telecommunication infrastructure development. PT INDOSAT provides the funds, manpower for project managements, and efficient methods of procurements. At the completion of the project, the operation and maintenance, as well as the asset, will be transferred to PT TELKOM through the government.

5. INDOSAT IN THE INTERNATIONAL TELECOMMUNICATION COOPERATION

PT INDOSAT also contributes to the international telecommunication activities. Its contribution in the international fora has been proved. But more importantly, with the involvement of PT INDOSAT in the international telecommunication organization activities and international fora, it improved the understanding of an up-to-date world telecommunication development. This knowledge will be brought to the national fora, where PT INDOSAT acted as one source of input to the government regulatory body. This up-to-date input of the world telecommunication situation will make the government's function as a regulatory body could be exercised effectively. Therefore PT INDOSAT hopes that the regulation applied in Indonesia could follow the fast technology and demand development.

PT INDOSAT's participation in the world telecommunication development is also recognized. The involvement of PT INDOSAT in the world submarine cable networks as initial parties or just IRU user proved the commitment to support the international telecommunication development. PT INDOSAT also had several bilateral programs with foreign telecommunication administrations. Exchange of expertise program is also conducted by PT INDOSAT by means of providing satellite technology courses under the arrangements of Asia-Pacific Telecommunity.

6. THE ROLE OF ASEAN COOPERATION IN THE DEVELOPMENT OF REGIONAL TELECOMMUNICATION NETWORK

The ASEAN cooperation was formed by the five ASEAN Countries' Head of States in August 1968. The objectives of this cooperation is to promote and synchronize the South East Asia regional economic development among its member countries. As time moves on, the ASEAN cooperation is expanded, not only in the number of countries joining this cooperation, but also the area of cooperation is expanded as well. Today, the attention is not limited to the economic activities cooperation but also to area that supports economic developments. Telecommunication is also included and viewed as the important infrastructure in the economic development. It is the agreement among ASEAN member countries, that they need to coordinate their countries telecommunication operation and development to obtain the highest synergy to support the region economic development. This idea is behind the formation of a Sub-committee on Post and Telecommunication. The Sub-committee on Post and Telecommunication function to coordinate the ASEAN member countries' telecommunication operation and development. This Sub-committee meets once a year and reports the coordination results to the Minister in-charge of telecommunication and Minister of Foreign affairs.

Activities that has been done by the ASEAN countries in the light of cooperation can be listed out as follows:

a. Exchanges of expertise,

b. Sharing of resources, such as the use of ASEAN cable depot in Singapore,

c. Joint developments, such as the construction of the ASEAN optical submarine cable network,

d. Tariff policies, such as what Singapore and Brunei Darussalam done,

e. Common interest in the international fora, such as setting up a common position in the ITU meetings for the region's benefit, and

f. Technical standardization, such as the agreement on the type of cellular mobile communication system to enable automatic roaming for ASEAN countries.

Each year the development on the policies and the telecommunication facilities is reported by each country to the Sub-committee for coordination and guidance of future actions. All is done under the ASEAN spirit of cooperation.

The general objectives of these arrangements are to support each country's individual interests and goals on the development of the telecommunication facilities, as well as to secure the region from being used by other counties that have technological advantages compared to the regional countries. The cooperation is also intended to secure the member countries' competitive advantages in the world markets. The country's competitive advantage is very important to ensure the fast and continuous development of each country, by means of offering the best environment for investments, trades, and tourism. With this kind of alliance, the ASEAN member countries would also able to contribute lots to the development of Asia-Pacific region.

The difficulty in developing the economy may not be the same in each country. The opportunity for one country to overcome its development problem may also be different from country to country. In the globalization era, one country may come up as the winner in this competition, but it may not worth if other country can not survive.

Since telecommunication is a part of one country's infrastructure that plays an important role in the development of that country, we cannot separate telecommunication from other sectors. Cooperation among nations in developing their telecommunication infrastructures is a must in the spirit of getting the mutual benefit that can be realised as improvement in the country's development in all aspects. Therefore we should promote the cooperation not only among governments, operators and suppliers who are involved in the telecommunication activities. But the cooperation should also extend to others from other sectors as the users to identify how the telecommunication should be developed for the benefit of the country as well as the world.

As a member of ASEAN Group, we would like to see that we can start to promote the cooperation within the ASEAN member countries. What has been experienced by Indonesian telecommunication community may be learned by other members. The success of one country is also interesting to be studied by other members.

As a regional group, ASEAN can not isolate itself from the rest of the world especially the Asia-Pacific region. Therefore, the cooperation should then be extended in the international forum to face the future challenges :

- Based on recent developments in the world, we can expect that the competiton will become tougher among the telecomunication operators, among the telecommunication users, as well as among the nations.

- Technology will drive the development; who has the technology may control the world.

- Power, whatever the forms : financial, armed forces, or others, can be exploited negatively by a person, a group of people, a nation, or a group of nations.

Many international telecommunication forums or organizations have been established such as ITU, APT, PTC, PPM, APEC, and others. We should utilize these organizations more effectively and develop communication among them to avoid duplication and wasting of resources. The challenges are not only for developing countries, or developed countries, but for all of us.

7. CONCLUSION

Telecommunication is one of the important infrastructure which can influence the economic development of the country. Each country has a different difficulties constraint and ability to overcome this infrastructure problem. But what has been experienced by one country can and should be shared by the others.

As a world community, we cannot leave behind some countries under-developed. There is a strong relationship between telecommunication sector and other sectors. The telecommunication development should involve other sectors to get the optimum benefit for mankind.

The key is cooperation. It should be promoted and strengthened among nations. Let us work hand by hand in facing the future challenges. Strategic cooperation and alliance between nations or entities will improve the nations or entities' competitive advantages.

GLOBAL DREAMS AND REGIONAL REALITIES

Mankind has always had universal dreams of unity, brotherhood, perfection behind, or beyond the more pedantic realities of village, tribe, nation, religion, or culture. As we race towards the 21st Century, talk increases of a new world order, a New Age, a global ethic and so forth, and this is the language of politicians and the ordinary man not just preachers, prophets or philosophers.

The telecommunication community shares a common dream - Arthur C Clarke's "global village" with networks enabling anyone to talk to anyone else anywhere, anytime. Computer and communication hardware and software technologies are advancing rapidly to make this dream come true. The roll out of SDH transmission, ATM switching, intelligent networking, millimetric and satellite based cellular is a universal phenomenon matching the globalised needs of commerce, finance, and industry. Advances in the production of memory devices and translation machines are accelerating the day when remote access to the accumulated wisdom of mankind will become commonplace, transforming the long-established habits of obtaining and providing health care, education, and work.

At the same time, transport technologies can be expected to make similar radical breakthroughs. Cutbacks in military expenditure can release resources for conversion programmes not only in Russia but also in Europe, Japan, and the United States. Supersonic passenger planes cutting travel time from Washington to Tokyo to 2 hours, and high speed rail linking the major cities of Europe in 1-2 hour travel times will help globalize the mobility of people to US levels which are the highest in the world. Microplanes may also replace the motorbike and extend the distances coverable by single person transport modules.

The portable phone will match the ever more mobile person. The hard logic of the telecommunication and transportation revolutions is to extend each individual's access to and accessibility from all parts of the physical, intellectual and cultural worlds. At home each

person will have access to information, entertainment, and real live events wherever generated; the rest of the world will be as accessible to the person on the move as today's offices or factories to the average commuter.

The Juggernaut of Technology is so strong and all pervasive that there is no longer any question of whether the telecommunication and transportation communities dreams will come true; it is only a matter of how and when.

The how and when will be determined by the realities that shape the wealth of nations, international and national resource allocation, regulation, decision-making. It is in this crucial area that regional factors cut across global desiderata.

The meltdown of the Iron Curtain has unleashed seismic changes in the geopolitical landscape. The EC of 12 looks set to become an EC of 20, 25 or 30 as EFTA, Central Europe, and the Soviet Republics redefine the shape of the European Community from a Western European entity into one that stretches from the Atlantic to the Sea of Japan and from the Arctic to North Africa. Few in the EC and certainly hardly any in the PTTs of the EC recognise the significance of these changes now in train.

Without in any way losing its central global role, the USA seems set in giving the Americas a new cohesion as a trading bloc if the NAFTA concept moves south beyond Mexico.

At the other end of the Pacific, a new trading community seems to be clustering around Japan as the Pacific Rim countries of Asia knit ever closer together in the wake of the explosive economic growth they are undergoing.

A fourth distinctive group may emerge if the Middle East Peace Process reaches a positive outcome liberating the countries of Islam from their obsession with Israel - namely the Islamic Community of

nations stretching from he Atlantic to the Pacific and from South Russia to South of the Sahara.

These regional fallouts in the wake of the end of the Cold War are macrocosms of the sort of divisions which are commonplace in our great metropolitan cities of today - New York, London, Tokyo, Hong Kong all contain distinct communities with differing interests and life styles while enjoying the same forms of telecommunications and transportation.

Telecommunications and transportation might be creating and serving a borderless world but they cannot remove the inner borders set by different communities of interest for themselves. Quantitative tariff barriers can be reduced to zero but the qualitative so-called non-tariff barriers create new constraints and are more difficult to remove.

The drive towards the global village, the global network, the global market place is accompanied by the equal and opposite drive towards regional, local, and eventually individual customization.

This is not necessarily a contradiction and can be compared to the familiar telecommunication model of the private customer, the local telco, the long-line and international telco, the PSTN and private networks all interacting in a network of networks.

Regional free trade zones can contribute towards achieving the global objectives of GATT so long as they are outward looking and open to interaction with other Regional free trade zones. The protagonists of EC, NAFTA, and the as yet unformulated Asia Pacific Group, all state that they are open and outward-looking.

In the case of the two regions on each side of the Pacific, this claim seems to be justified. Indeed, while there is no Pacific Treaty or Charter and no formal Pacific Economic Community, the movement of people and ideas across the Pacific has been dramatic.

The economic, social, and political transformation of South-East and North-East Asia has been aided and abetted by the migration of Asians to North America and Australasia and the export of North American ideas and technology to Asia. California, the Pacific North West and British Columbia are great havens for the new Asia rising in America. Meanwhile in Japan, Korea, Hong Kong, Taiwan and the ASEAN countries, the best of North American business and technological experience is absorbed and applied in dynamic wealth creating ways.

The peoples of the Pacific Basin from Australasia in the South via ASEAN and the great coastal cities of China up to Sakhalin and Alaska in the North including Japan and Korea, and from Chile in the South of the Americas up to Alaska via Mexico, USA and Canada constitute around 1 billion in number with many languages, religions, and political systems. The movement of goods, people, services and finance between this region is already the most dynamic and extensive in the world, more or less ensuring that the 21st century will be the Pacific century with the largest ocean in the world being transformed into an inland lake.

This prospective Pacific economic miracle generating some 60% of world GDP is supported and reinforced by the roll out of a new telecommunications infrastructure.

Before moving to the FCC Al Sikes presided over the NTIA study which set the universalisation of Broadband ISDN services as the US national telecommunication goal by the year 2000. In Japan, NTT is dedicated to bringing fibre to every home by the year 2015. In both the USA and Japan telecommunication deregulation and network pluralism are driving the delivery of this new infrastructure. Across the Pacific it was also the FCC decision to introduce international facilities competition that gave a kick start to the new catscradle of submarine fibre optic cables crisscrossing the Pacific. It was only 5 years ago that the pioneering initiative of IDC, Cable and Wireless and Pacific Telecom in planning NPC, the first direct link between Japan and the United States, the two largest economies in the world, was dismissed by the great and the

good in the telecommunication community as a misguided aberration. Today, the competitive response of the traditional carrier community has been massive and continuous: instead of TPC 3 which was supposed to serve the Pacific requirements up to 1996, we now have NPC, TPC 4, TPC 5 and 6, PACRIM East and West, PAC, H-G-P,and there is now talk of APC 2.

The Pacific Ocean has no landlords. The Ocean floor is rent free and it is already cheaper to call San Fransisco from Tokyo than Hiroshima from Tokyo. The introduction of broadband electronic highways will accelerate the introduction of electronic markets for an array of goods and services, and electronic platforms for the handling of health, education, R&D and live events. With ATM switching and 10 gigabite transmissions systems, there is no economic or technological reason why NTT's famous local 10 yen zone should not encompass the whole Pacific basin. The boundaries between local, long-line, and international will collapse and carriers will have to learn to treat the whole region as a single market when constructing their networks and service offerings of the future.

The single Pacific market will emerge bottom up as part of a common sense technological and economic solution to the benefit of its 1 billion customers with telecommunication and transportation technologies as key catalysts.

The second super Region will be the EurAsian landmass. Here politicians and civil servants rather than technology are predominant. The ever expanding EC is essentially a top down phenomenon. While EurAsia's 800 million people have many languages and political systems, there is far greater cultural homogeneity in the Region from Dublin to Vladivostok than in the Pacific basin.

Because it is a landmass, there are many landlords and many boundaries to be crossed. Paradoxically, the vast oceanic divide and the cultural heterogeneity betwen the nations on both sides of the Pacific create an openness to technological and economic homogeneity, whereas in EurAsia the cultural homogeneity and physical proximity

have created barriers to crossborder technological and economic penetration and an instinctive protectionism in defence of national identities. The nations of EurAsia suffer from what the psychologists call "core complex" - an inability to strike the right balance between fission and fusion in relations with each other.

In telecommunication terms, the Eurasian landmass is a patchwork quilt of different networks. In an excellent editorial on 22 November 1991, the *Financial Times* made the following pertinent observations:

> "Efficient transcontinental telecommunications networks underpin the US economy. Europe, by contrast, makes do with a patchwork of domestic networks. However efficient these networks may be for local communications - and most are far below US standards - communicating from one end of the continent to the other is frustrated by high prices, poor quality and a web of monopolistic restrictions."
>
> "The heaviest burden Europeans bear as a result of the continent's fragmented networks is the price of long-distance calls. A three-minute call from Boston to Washington DC - a distance of about 650km - costs the user 69c at peak rates, says the consultants, Logica. But a call from Paris to Milan, about the same distance, costs FFr11.37 ($2.08), nearly three times as much. One from Milan to Brussels, again the same distance, is four times as much - L3,556 ($2.94). At off-peak times, the disparity is even greater."
>
> "Although crossing frontiers is particularly expensive, long-distance calls within one country are also costly by US standards. A call from Marseilles to Paris costs FFr6.51 ($1.19), while one form Naples to Milan is L2,113 ($1.75). US consumers can call from Miami to Anchorage - 10 times the distance - for only 91c."

At Maastricht, the EC politicians mapped out routes towards monetary and political union to build on the moves to achieve a single market by 1993. Nothing, however, was done to alter the structure of the EC telecommunications markets, where the PTT monopolies continue to dominate within the boundaries of national sovereignty. Post Maastricht, the lack of PanEuropean long line carriers is anachronistic. For a call from London to Paris or Paris to Bonn to be classed as international - that is crossing national frontiers - is absurd when these national frontiers are being abolished for purposes of the movement of goods, services, and people. As cross-frontier talk constitutes some 5-7% of PTT revenues, the establishment of PanEruopean and eventually PanEurasian carriers would not have a large impact on the revenues of the PTT monopolies. The US and Japanese experience demonstrates that competing long line carriers do not damage local monopolies. Indeed, the reverse is true. There are 20 times more telephone lines per head of population and each line is used 3 times more in USA than in Europe.

The European PTT counter-argument does, however, deserve a hearing. There is a strong feeling in Europe that transmission networks are a natural monopoly and there is a case for treating national telecommunication transmission networks like the electricity or railways grid and liberating access to this grid completely for all services from the bottom to top of the OSI ladder. The regulators in Sweden and Germany are reflecting on such matters and the Communication Unions in Britain have been toying with similar ideas. Network monism rather than network pluralism might, therefore, be the European road into the ATM/SDH era. The burden of universal service is the other justification used in support of the continuance of

special privileges in infrastructure operation and voice conveyance. Not ony does this ignore the UK, US and Japanese experience, but overlooks that after more than a century of keeping faith with the monopoly model, the vast majority of ITU member countries are nowhere within reach of achieving universal levels of penetration of the basic telephone instrument.

As the old Scottish ballad says - there is a high road and a low road to Loch Lomond. It will be interesting to see whether the network monists or the network pluralists wins the race to arrive in the Scotland of the Information Era!

LOW EARTH ORBIT SATELLITE SYSTEMS

Jill Abeshouse Stern*
Michael D. Berg**

INTRODUCTION

Reflecting current interest in low earth orbit satellite systems, in 1990 six companies sought authorization from the Federal Communications Commission (FCC) to use low earth orbiting satellites for a range of domestic and international telecommunications services including mobile voice, data, personal communications and position location. Further demonstrating the high level of interest in this new satellite communications technology, in June 1991 three additional companies submitted low earth orbit satellite proposals to the FCC.

This domestic activity parallels increased international interest in the commercial potential of low earth orbit satellites, and has brought to the forefront the domestic and

** Mr. Berg, also a partner in the Miller & Holbrooke law firm, specializes in communications law (regulation, policy and litigation) in the areas of broadcasting, cable television, satellites, common and private carriers and international telecommunications. He chairs the "Video in the Pacific" session during PTC '92.

defined as satellite systems in non-geostationary orbit.[3] Geostationary orbit lies approximately 22,300 miles above the earth in the plane of the earth's equator. Satellites in a geostationary orbit remain in a fixed position relative to the earth.[4] In contrast, LEO satellites are not geosynchronous and are placed into a "lower" orbit. For example, Motorola's Iridium system, discussed below, is to be located 413 miles above the earth; the orbits specified by other LEO applicants range from 5,600 miles to 550 miles above the earth. LEOS circle the globe, either pole to pole, around the equator, or anywhere in between. As a result, LEOS are inherently able to achieve nationwide or

---

[3] Although there are different types of non-geostationary satellites (e.g., low earth orbit, elliptical orbit, circular polar orbit), this discussion uses the term LEO broadly to describe all non-geostationary satellites. Although the terms "small satellite" and "LEO" are often used interchangeably, it should be pointed out that the two may be but are not necessarily the same. LEOS are typically small satellites in that they weigh and cost less than the large geostationary satellites historically used. (Small satellites are generally defined as those weighing less than 1000 lbs. and costing less than $20 million dollars. See Stern, Lacohie & Zygmont, An Assessment of Potential Markets for Small Satellites, 5 (1989).) However, small satellites can be, and have been, proposed to be placed into geosynchronous orbit. See Application of Afrispace, Inc., FCC File No. CSS-90-017, filed July 23, 1990. Small satellites are particularly suited for low earth orbit because the higher power levels and other technical characteristics necessary for communication from geostationary orbit are not required. In addition, as the result of savings in construction and launch costs, small satellites offer promise for a variety of communications and other commercial uses.

[4] See 47 C.F.R. § 2.1(c) (1989).

policy. To the extent that geostationary satellites have been the dominant technology and formed the model for domestic and international regulation, LEOS raise novel regulatory and policy issues that must be considered and resolved if LEOS are to fulfill the public benefits envisioned. Indeed, whether the full potential of LEO satellite systems is realized in the future will be determined in large part by how these systems are treated from a spectrum allocation and regulatory standpoint.[8]

While some of the differences between geostationary and non-geostationary satellites are highlighted above, it bears emphasis that both types of satellite systems share many similarities from a communications standpoint and should be viewed as alternative means of providing vital communication services.[9] Although beyond the scope of this discussion, among the international regulatory issues potentially applicable to both LEOS and GEOS

---

[8] The FCC also needs to carefully examine its satellite regulatory scheme to determine its impact on LEOS. For example, the FCC has interpreted the filing fee for space system applications (including the $70,000 launch application fee) to apply on a per satellite basis. In that LEO systems typically involve multiple numbers of satellites, a disproportionate fee may result. Based on a 77 satellite system, for example, Motorola could be required to pay over $5 million solely for its FCC launch application.

[9] The FCC has required LEO applicants to follow the same application procedures as other satellite applicants. Those procedures are set forth in Domestic Fixed Satellite Service, 93 F.C.C.2d 1260 (1983) at Appendix B.

that can potentially be provided by non-geosynchronous satellites.

a. Proposals Below 1 GHz.

Spectrum allocations for LEOS have been requested in the 137-138 MHz and 148-149.9 MHz bands.[13] A petition for rulemaking to establish a frequency allocation for a Non-Profit International Low-Earth Orbit Fixed Satellite Service in the 200-800 MHz bands has also been filed.[14] In addition, applications have been filed for licensing of LEO satellite systems in the 137-138 MHz and 148-149.9 MHz bands, and in the 200-800 MHz bands, respectively.

Orbital Communications Corporation (Orbcomm) proposes to operate a 20-satellite system of low earth orbiting satellites that would provide two-way data communications and position determination services primarily to mobile subscribers in the 50 states, Puerto Rico/Virgin Islands, U.S. Pacific Islands and the

---

[13] See Petition for Rulemaking of Starsys, Inc., RM-7399; Petition for Rulemaking of Orbital Communications Corp., RM-7334, Public Notice Report No. 1814, released April 4, 1990.

[14] See Petition for Rulemaking of Volunteers for Technical Assistance, RM-7612. VITA has proposed two alternative frequency utilization plans.

MHz bands consisting of two low-orbit satellites.[18] The VITASAT system would use fixed or portable earth stations to provide educational, health, environmental and disaster relief communications services to developing countries.

From a procedural standpoint, the FCC has not yet indicated how it intends to process the pending applications of Orbcomm, Starsys, VITA and Leosat. A threshold issue is the availability of spectrum for the LEO systems, both domestically and internationally. The FCC has recommended to the U.S. Department of State, in connection with the WARC-92 proceedings, that spectrum in the 137-138/148-149.9 MHz bands be allocated internationally for LEOS on a primary basis.[19] This international recommendation suggests that the FCC is likely to take favorable action with respect to a domestic allocation in the same bands. Apart from the spectrum issue, the FCC needs to consider licensing and regulatory policies for the proposed services.

---

[18] Application of VITA, FCC File No. CSS-91-007-(3), filed September 20, 1990. The VITA application was accepted for filing on April 11, 1991. See Public Notice, Report No. I-6563, released April 11, 1991.

[19] See An Inquiry Relating to Preparation for the International Telecommunication Union World Administrative Radio Conference for Dealing with Frequency Allocations in Certain Parts of the Spectrum, Report, Gen. Docket No. 89-554, FCC 91-188, released June 20, 1991 ("WARC Report") at 17. WARC-92, and its significance for LEO proposals, is discussed in greater detail below at pp. 11-14.

Unlike the companies interested in spectrum below 1 GHz, these five companies have proposed to use spectrum currently allocated to the Radiodetermination Satellite Service (i.e., 1610-1626.5 MHz and 2483.5-2500 MHz).

Ellipsat has proposed a two-phase satellite system, ultimately consisting of 24 elliptical orbit satellites, to provide RDSS and mobile voice (cellular) services to vehicles within the continental United States and domestic offshore points. Through the use of small satellites, Ellipsat projects that it will be able to augment existing cellular services at a cost comparable to terrestrial systems. Motorola's Iridium system will consist of 77 low earth orbit satellites in seven polar orbits providing worldwide digital mobile personal communications services using frequencies in the 1610-1625 MHz band. Motorola plans to work through international partners to offer its proposed services which include paging, messaging, voice, position location, facsimile and data services.

Loral proposes a 24-satellite system, called Globalstar, offering radiodetermination satellite, voice and data communications. Qualcomm, one of the principals of Loral, is currently a provider of radiodetermination satellite services using in-orbit domestic fixed satellites. TRW plans to construct the Odyssey radiodetermination and mobile communications satellite system, consisting of twelve satellites in "medium"

2. WARC-92.

In 1992, the International Telecommunications Union (ITU) will convene a World Administrative Radio Conference to discuss specific issues involving the international allocation of radio spectrum for mobile services. The WARC Agenda, adopted in June 1990, proposes, among other issues, to "consider possible allocations of up to 5 MHz of a frequency band below 1 GHz to low-orbit satellites on the basis of appropriate sharing criteria."[23] It is noteworthy that the proposed scope of WARC-92 did not initially encompass LEOS, but the proceedings were later expanded to include consideration of a generic LEO allocation.

As formulated by the WARC Agenda, the issues of spectrum allocation and sharing criteria for LEOS will need to be considered at the 1992 conference. International regulations do not presently define non-geostationary satellites or specifically address use of allocated frequencies by such satellites.[24] One issue that needs to be addressed at WARC, for example, is the applicability of the ITU advance publication, coordination and notification procedures to LEOS.

---

[23] See Section 2.2.4(d), WARC-92 Agenda, 45th Session ITU Administrative Council, Document CA45/7042-E (June 20, 1990).

[24] The only apparent reference to non-geostationary space stations in the ITU Radio Regulations appears in Article 29, Section II, which sets forth standards for control of interference to geostationary satellite systems.

in response to comments raising the issue of LEOS above 1 GHz,[28] the FCC issued a Supplemental Notice of Inquiry in March 1991 to address LEOS and other issues.[29] In the Supplemental Notice, the FCC proposed to allocate additional spectrum above 1 GHz for LEO MSS use.[30]

In its final WARC Report, released June 20, 1991, the FCC recommended that the 1610-1626.5 MHz and the 2483.5-2500 MHz bands be allocated for mobile satellite use, for both geostationary and low earth orbiting systems, on a co-primary basis with RDSS.[31] It also proposed to allocate the 1850-1990 MHz band for mobile satellite use, either LEO or GEO, on a primary basis. The FCC indicated that it is prepared to work with other administrations at WARC-92 to develop the necessary procedures for coordination of LEO and GEO systems.[32]

WARC-92 will provide a critical first opportunity to consider the international spectrum allocation and regulatory

Voice Enhanced Applications Enabled Through the Use of an Application Program Interface

Daniel E. Stone

IBM Corporation

Abstract

Managing the interaction of switches and computers to enhance existing business applications, which rely on the use of a telephone, represents both a tremendous business opportunity and a formidable technical challenge. This paper describes how an architected telephony services application program interface enables the enhancement of these business applications, overcomes the technical challenge, and provides multiple benefits to both the business employing the technology and the end user, their customer.

Introduction

Over the past decade many changes have occurred in the telecommunications world; new organizations, new businesses, new technologies, new services to users. In spite of all this change, basic voice service is still key to modern business communications. The transport facilities for delivering that voice service have been on a constantly increasing slope of value, quality, and reliability. There is now a need to ensure that the handling of the call, both inbound and outbound, is done in a way that provides for the same degree of quality and efficiency as the transport.

Any successful business that depends on large volumes of business transactions conducted over the telephone will have already taken maximum advantage of data processing to improve the handling of these transactions. On line customer record systems, exhaustive account management and order tracking, efficient order processing and inventory management have all been implemented to maximize productivity and customer service and minimize costs. This effort will continue unabated but there are now available new technologies and products to realize even greater efficiencies in the processing of a voice based business transaction.

Customer Environment

Many businesses that handle large volumes of voice based business transactions do so through a Call Center. A Call Center may support inbound call services such as reservations, order processing, account enquiries, credit verification, and help desk. Outbound services such as lead generation, overdue billing enquiries, appointment confirmations, and many others may also be supported. In either case a Call Center can be characterized as consisting of a set of agents who are 1) answering an incoming or placing an outgoing call, 2) prompting the client for information, and 3) providing some form of service. The agents will usually have a computer terminal as a basic part of their work station to assist them in the processing of calls.

Normally, the call handling and data processing activities are coordinated only through the actions of the agents themselves. No direct linkage exists between the data processing systems and the voice processing (switch or automatic call distributor) systems to assist the agent. This means that the agent has to spend time accessing data records related to the call once the client is identified and the reason for the call established. If the agent has to transfer the call to another agent this will most likely result in the second agent having to start over from the beginning to access data records related to the call.

Voice Transaction Automation

Switch Functionality

In an effort to automate the processing of telephone based business transactions many technological improvements have been introduced into the systems involved. Modern Private Business Exchanges (PBX) and Central Office based Centrex services offer many features which improve the handling of incoming calls. These features include such capabilities as call forwarding, conference calls, call logging, call holding, direct inward dialing, and on-hook dialing (hands free operation).

1355

- Alter the set of answering prompts based on time, date, or other factors
- Request information from the caller
- Interpret DTMF responses or perform speech recognition
- Access data in attached hosts depending on responses provided by the caller
- Accept input data from the caller and send to attached hosts
- Identify the caller via requested identification information
- Transfer the call to a live agent
- Terminate the call

Based on the functions identified above, the typical VRU is capable of either handling a call completely independent of human interaction or serving as a pre-processor for complex transactions, only handing off the call once all the preliminary data has been gathered and the caller identified to the point of ensuring that the call will be processed by the appropriate person. VRU's can also provide coverage of critical telephone numbers during periods of peak traffic or during off business hours.

Voice/Data Integration Directions

Standards Activities

Recognizing the need to merge the automation capabilities inherent in data processing facilities with the automation capabilities available through modern digital, stored program controlled switches manufacturers of both sets of equipment have cooperated with national and international organizations to develop draft standards defining switch to computer application interfaces.

The European Computer Manufacturer's Association (ECMA) is developing a standard for Computer Supported Telecommunications Applications (CSTA). The American National Standards Institute is developing a standard for Switch-Computer Applications Interface (SCAI). Both standards have the same purpose, namely to specify an architecture that is both service and implementation independent and to define a sufficient set of service elements and protocols to support a variety of shared applications between telecommunications and data processing environments. Both standards are nearing completion and should be approved within 1992.

Current Product Offerings

To be consistent with standards directions, any proposed product offering must define a well architected telephony services API which is independent of the platform on which it is implemented. The API should also be supported by a telephony services subsystem to provide the switch protocol mapping between the API and the various switches to which attachment is supported. This function of the telephony services subsystem allows application programs to communicate with multiple switches without being concerned with the unique interfaces and protocols of each switch. A brief overview is provided of the design considerations inherent in architecting a telephony services API and its underlying telephony services subsystem. This is followed by a more detailed description of the API structure and the solutions which are enabled by such an API.

Application Program Interface

A telephony services Application Program Interface (API) is designed to facilitate the communication between a host based application program and an attached switch or ACD unit. The API consists of a set of program calls which, when invoked by an application program, result in the execution of a supporting function in an underlying telephony services subsystem. The subsystem processes the program call and, if no errors are found, formats the request and communicates it to the attached switch or ACD. The API also consists of a set of messages which define call progress events or switch or communication line status. The

A directory number is the address used to identify a party. A directory number, however, does not uniquely identify a party's participation in a telephone call. To uniquely identify a party's participation in a given call, a connection ID must be created. The telephony services subsystem will create new connection IDs, as appropriate when a party, or an application program acting on behalf of a party, requests various services from a switch. The subsystem will also discard connection ID's, as appropriate, when other services are requested from a switch.

Telephone Connection States

As previously discussed, the model of a telephone call can be described in terms of parties and connections. It is now necessary to introduce the concept of "states" of a connection.

At any instant, a party's connection is in one of several states. The state that a connection is in determines what the next set of actions may be and whether a request involving that connection can be fulfilled. When a connection leaves a state, it makes a transition from that state to another. The following sections describe the 5 individual states that a connection within a telephone call can enter. These states are maintained by a switch for the parties local to that switch. When a switch receives a request, it is able to validate that any specified local party is in the correct state for the request to be fulfilled. If the request specifies remote parties (that is not local to the switch), the switch must send the request to the switch to which the remote party is connected for state validation and processing.

Idle State

There is no telephone call in process, and therefore no connection IDs representing this connection.

Pending State

An outgoing telephone call involving this calling party is being established. The calling party's connection enters this state when a call setup occurs. The call setup could be either the party's line going off-hook or the receipt by the switch of a Setup message from an ISDN phone. When the calling party's connection enters this state, a new connection ID is created to represent the calling party's connection into the pending telephone call. The calling party's connection leaves the Pending state and enters the Connected state when all the digits required to proceed with the telephone call have been collected by the switch.

Routing State

An incoming telephone call involving this called party is being routed to the party. The called party's connection enters this state when the validation of the calling party's dialed digits has been completed by the switch. When the called party's connection enters this state, a new connection ID is created to represent the called party's connection into the pending telephone call. The called party's connection leaves the Routing state and enters the Alerting state when the called party's identity and routing location have been determined by the switch and the switch has begun to alert the called party's phone.

Alerting State

An incoming telephone call involving this called party has been routed and the party's phone is being alerted by the switch. The alerting could take the form of a party's phone ringing or the sending of an Alerting message to an ISDN phone. The called party's connection enters this state when the alerting begins. The party's connection leaves this state when one of the following occurs:

- The call is answered, in which case the called party's connection enters the Connected state.
- The call is rejected, perhaps because a switch-specific time elapsed without the called party answering the call, or the calling party disconnects. In either case, the called party's connection ID that was created in the Routing state is discarded.

Transition Seven, From Alerting to Idle

A called party's connection passes from the Alerting to the Idle state if one of the following occurs prior to the incoming call being answered:

- The calling party disconnects
- The incoming call is rejected, perhaps as a result of a request from an application program.

Transition Eight, From Alerting to Connected

A called party's connection passes from the Alerting to the Connected state when the called party answers the incoming telephone call.

Transition Nine, From Connected to Idle

A party, regardless of whether the party was the called or calling party, passes from the Connected to the Idle state when its participation in the telephone call ends.

Program Calls

Application programs communicate with a switch by executing program calls. These program calls are used to exchange requests, responses, and other messages with the switch and to establish the characteristics to be associated with a telephone call profile.

Call Profiles

A telephony services subsystem will need to implement the concept of call profiles to allow it to provide a switch and device independent support to an application program. Through the use of call profiles a telephony services subsystem can maintain the unique characteristics of attached switches. The application program will need to initialize a call profile before communicating with a switch. It is possible that a program will use more than one call profile when communicating with a specific switch, but it will need at least one per switch.

Program Call Types

The program calls defined by the telephony services API will need to cover a range of functions, both for communicating with the attached switch and for requesting services from the telephony services subsystem. Although the list of supported program calls could be quite extensive it is clear from existing implementations that less than 50 program calls are needed to define an API that is capable of supporting programs to handle any aspect of a telephone call. A partial list of some common program calls that would be included in a telephony services API are described in the following:

Answer Call: Used by a program to alternate between two existing telephone calls, an active and a held call, by placing the active call on hold and retrieving the held call.

Disconnect: Used by a program to remove a party from its current call

Extend Call: Used by a program to extend an existing telephone call; that is, to place an existing call on hold and attempt a connection to another party.

Make Call: Used by a program to establish a telephone call

Monitor: Used by a program to register an interest in being sent specified call-progress event messages for a specified resource, such as a directory number.

Reject Call: Used by a program to reject an incoming telephone call that has been routed to a party.

Return Control: Used by a program to return control of a telephone call to the processing switch.

Operating Environment

Besides defining the program calls and messages to be used by an application program, a telephony services subsystem needs to provide mechanisms for system administrators to use in maintaining lists of resources available to the application programs. In the case of application programs which are managing telephone calls through one or more attached switches, these resources mostly consist of lists of directory numbers available to them and some means of identifying individual switches and their characteristics.

An application program, written to conform to an architected API, can be made independent of the unique protocols supported by a specific switch but it cannot be totally ignorant of the functions supported by that switch. One switch can support a different set of functions from another switch. This can be true whether considering different manufacturers or different switch types from one manufacturer or different levels of the same switch type from the same manufacturer. The application program should be designed and written taking the target switch and its supported functions into account. When the case occurs that an application program makes a request of a switch for a function that is not supported, this fact can be determined, to the greatest extent practicable, by the telephony services subsystem. Where it is not possible for the telephony services subsystem to make this determination, messages should be defined within the API to allow the switch to notify the program that it has requested a function that is not supported.

Enabled Solutions

Based on the availability of an architected Application Program Interface providing the level of functionality implied in the preceding sections, it is possible to implement application programs which can supplement the telephone call handling actions of a set of live agents. This capability automates and enhances many common business applications involving high volumes of telephone traffic. A few examples are described in the following sections.

Intelligent Answering

Intelligent Answering utilizes the capability of a telephony services application program to identify either the calling party, the called party, or both. This capability relies on one or more Network Services, such as Automatic Number Identification (ANI) or Dialed Number Identification Service (DNIS), but its real value comes from the ability of an application program to access customer information based on the numbers provided in the service. Once the number of a caller is passed to the application program from the switch, for example, the customer record database can be searched based on that number and any degree of relevant information can then be presented to the live agent at the moment of transfer. This information could be as straightforward as the customer's name (individual or company) or it could be a complete customer account history.

If only DNIS is being utilized, the information presented to the agent when the call is transferred could be pre-formatted order forms if the call is identified as being placed to the Sales Department or it could be claims forms if the call is being transferred to Customer Claims.

In either case, Intelligent Answering allows agents to answer the call in a more informed, personal manner. It also enables them to be more professional and productive. Since calls are handled more efficiently, more calls can be processed and customer holding time can be minimized. As a result, network costs for services, such as 800, can be reduced and telephone line utilization can be optimized or even reduced. All of this taken in total means that a company's overall responsiveness to its customers, vendors, and prospects is enhanced.

services API and its supporting subsystem an application program could determine the availability of multiple parties and establish a conference call. An agent could continue working until all parties were available.

Summary

This paper has described the customer environment involving the use of telephone based business transactions. It has proposed that the automation of these transactions, through the use of telephony service applications, can lead to multiple benefits to both the business employing these applications and to their customers.

The key to the automation of call handling, in many common business applications involving the use of telephone based transactions, is an architected, functionally rich telephony services application program interface. This API should provide an application programmer the ability to control all phases of a telephone call and automate as much as possible of the call handling process prior to handing off to a live agent. It should also relieve the programmer from being concerned with the individual protocols and interfaces of any attached switch or other telephone system. Such an API has been described and examples of the business solutions, which are enhanced by the use of applications based on this API, were provided.

Author Note and Copyright Information: It must be acknowledged that the concepts presented in this paper are based on IBM's Callpath Services Architecture. This is due to the authors corporate affiliation and familiarity with this proven architecture and related product offerings.

IBM continues to work closely with the aforementioned standards bodies and has made, as a stated design objective of Callpath Services Architecture, every attempt to ensure that minimal change, both to the API itself and to programs written to the API, should be required in order to communicate with a switch that supports the standardized protocols that are expected to be completed in the future.

DIGITAL SOLUTIONS FOR MOBILE SATELLITE COMMUNICATIONS

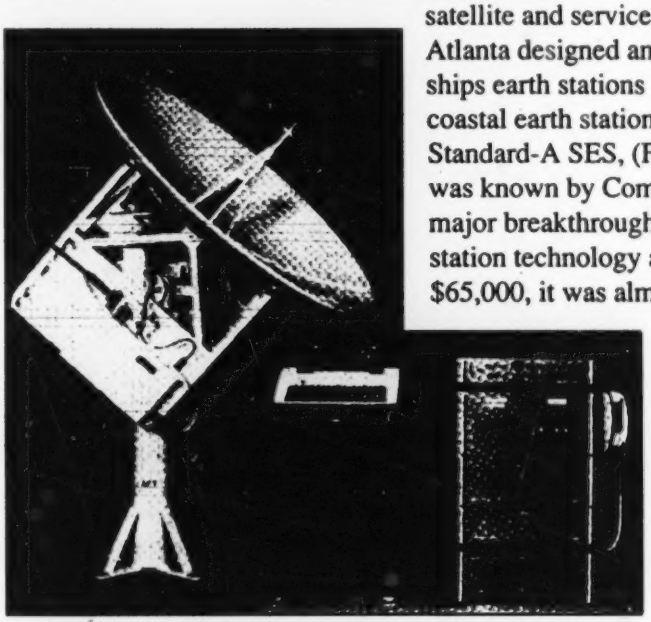
by Macy W. Summers, Director
Telecoms Business Development, Network Systems Group
Scientific-Atlanta, Inc.

Abstract: The 90's will be the decade of mobile satellite communications. INMARSAT's second generation birds are providing service to more than 14,000 users; Aussat will fly an L-band mobile transponder in 1992; Telesat Mobile (TMI) and American Mobile Satellite (AMSC) have the go ahead to construct their domestic mobile satellites. All of these satellite systems have tacitly agreed on common standards for digital mobile earth stations to provide low-speed data, fax, and compressed voice telecommunications to the mobile user community. This paper discusses a brief history of mobile satcoms and Scientific-Atlanta's mobile (MES) and land earth station (LES) family of terminals and systems.

Almost certainly, the decade of the 90's will be the blooming of Mobile Satellite Communications. The momentum that this adolescent industry has gathered is now unstoppable. Mobile digital earth stations are already under $8,000 and some are predicting high volume voice and data terminals in the $3,000 range by the late 1990's. This paper discusses the background of the mobile satellite industry and Scientific-Atlanta's (S-A) approach to the Geosynchronous Earth Orbit (GEO) mobile satcom and land earth station systems.

Background

In the early days of satellite communications, it was recognized by many that one of the enduring aspects of a satellite was its ability to reliably serve locations that were unreachable by traditional means. Ocean-going vessels and mobile vehicles far from the major metropolitan areas could be served by satellite as far in the future anyone could see. In 1975, Comsat General and Scientific-Atlanta began a collaboration for the commercialization of mobile satcoms. Comsat provided the MARISAT satellite and service. Scientific-Atlanta designed and built the ships earth stations (SES) and coastal earth stations (CES). The Standard-A SES, (Figure 1), as it was known by Comsat, was a major breakthrough in earth station technology and cost. At $65,000, it was almost ten times less expensive than the INTELSAT (fixed) single-channel voice terminal, and it included a stabilized pedestal to compensate for the roll and pitch movements of a ship in the open ocean. However, at $10/minute phone calls had to be of an urgent nature else



The world's first Mobile Earth Station, S-A Model 3055
Figure 1

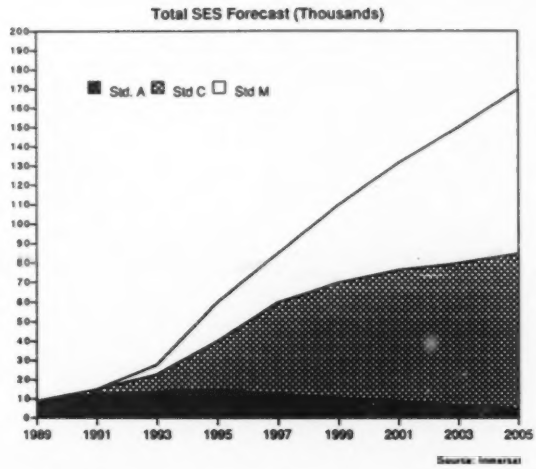
the cost of operating an SES might quickly outstrip the capital cost of the terminal.

Since that first mobile telephone call, made from a cargo vessel off the coast of Madagascar with an S-A Model 3055 MARISTAR® (SES), fifteen years of mobile satellite and terminal design experience have culminated in a new era of mobile services.

The second stage of mobile satellite came with the inception of INMARSAT. INMARSAT is somewhat patterned after the INTELSAT system and today has 64 member nations as its signatories. Although the International Maritime Satellite Organization was formally established in 1979, actual operation did not start until the Comsat joint venture, MARISAT, was turned over in 1982. Since that time, the INMARSAT earth station base has grown from approximately 1,500 to over 14,000, a compounded annual growth rate of over 25 percent.

INMARSAT's New Strategy

With the spectacular success of the INMARSAT service came some fundamental growing pains. Originally designed for 10,000, the four ocean region satellite service has now more than 14,000 SESs. In addition to the obvious satellite bandwidth and power implications, by the mid-1980's INMARSAT's service offering had become antiquated; analog voice and telex was not what the users wanted. SES prices had fallen to $35,000 each, but with C-Band (fixed) VSATs already under $10,000, SES users were complaining. New land mobile earth station (LMES) users wanted voice, fax, data and position reporting. Ship owners wanted on-line fleet management to aid in optimizing commodity shipment prices and costs of transportation. Yacht owners clearly wanted voice and weather reports. INMARSAT decided that what the market really needed was a wide range of telecommunications options to fit the specific



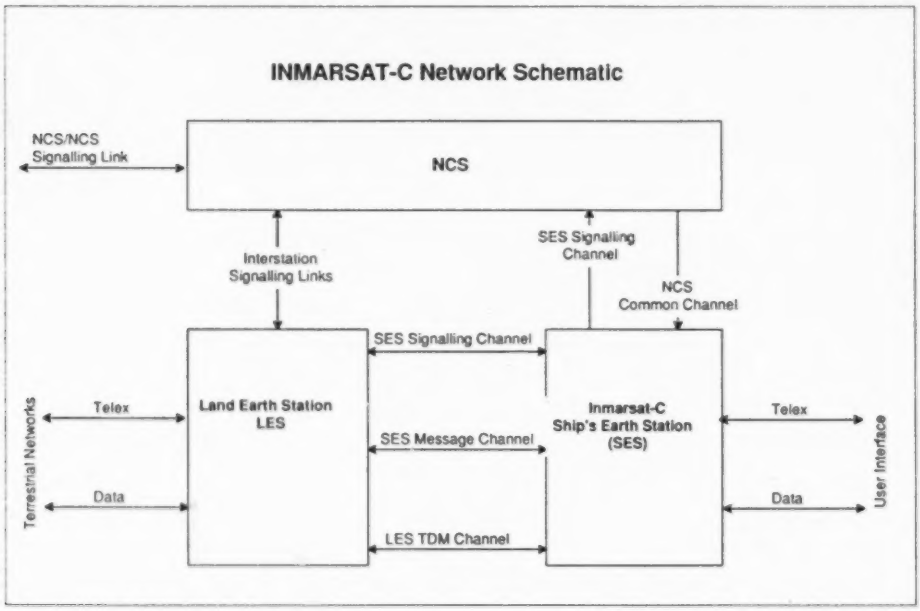
needs of their varied users. The strategy was to a) launch two new, higher power series of satellites(-2 and -3), b) completely phase out the analog services by 1995, c) introduce two new classes of digital telephony earth stations and d) one new data-only MES that could be made in volumes to sell for one-tenth of the original Standard-A. With these sweeping changes in place, INMARSAT was ready to grow again. The above Figure gives INMARSAT's SES growth projections.

INMARSAT also did not miss the opportunity to offer Aeronautical Mobile Satellite Services (AMSS). The global aviation industry, while much more conservative than their terrestrial bound counterparts, probably has the most to gain from satellite-based mobile communications. On long-haul transcontinental flights, Aeronautical Mobile Earth Station (AMES) passenger communications services could bring large growth revenues to a very competitive industry. So key is this segment of the mobile satcom market to the future revenues of INMARSAT that the INMARSAT-2 F1 bird (launched in March) has been positioned over the Indian Ocean Region (IOR) and will primarily carry air traffic control communications to aircraft through the UK and Singapore CESs. Most major transcontinental airlines have INMAR-

SAT trials underway and have plans to equip all long-haul aircraft with AMESs by 1996. One leading AMSS industry spokesman, Michel Gelinas, Vice President, Aeronautical Services, of IDB Aeronautical Communications, Inc. predicts "of the estimated 14,000 commercial aircraft globally, (he expects) equipping 30% of them at annual revenues of $2 billion in the year 2000."

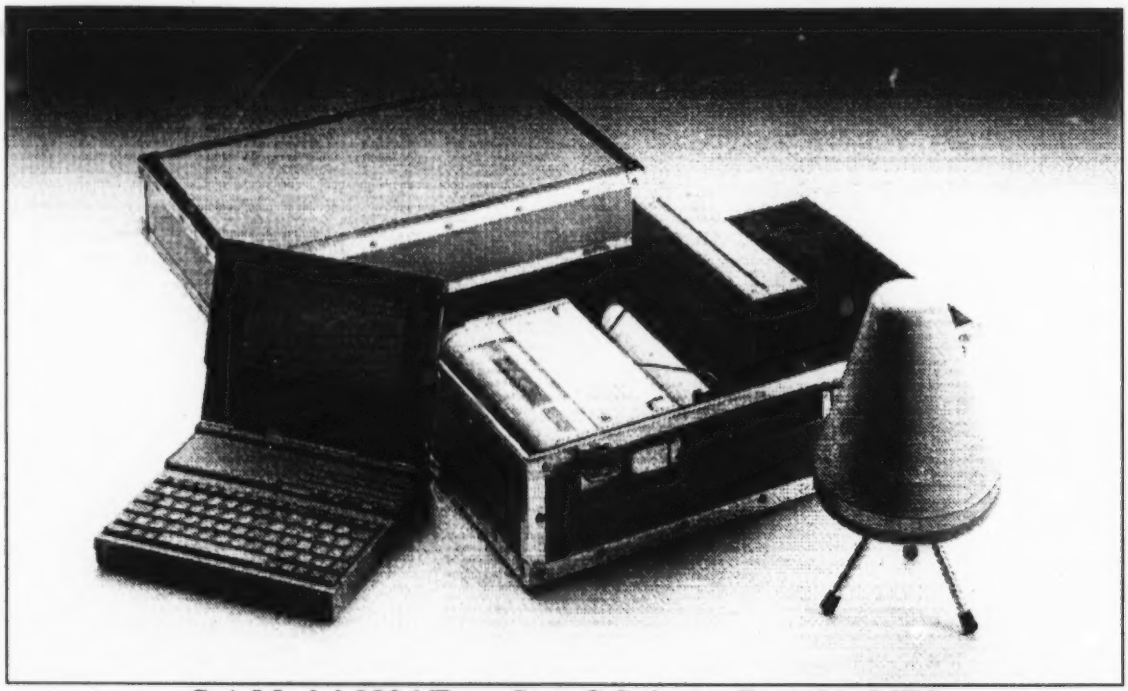
INMARSAT C, M, and B MESs

In 1989, INMARSAT-C (Inm-C) was announced to serve the low-end of the maritime and land mobile data markets. This store-and-forward, data-only "mobile VSAT" is typically connected with a PC or data terminal which formats the message to be sent. The Inm-C then sends packetized data to a LES through a slotted Aloha/reservation TDMA satellite channel where the message is switched into the public networks. (See the above Figure for the Inm-C network schematic diagram). The Inm-C immediately found acceptance in the targeted markets. Although some software and roll-out issues soured many of the initial trials, the market is now robust with more than 4,000 terminals and nine LES operational around the world.



INMARSAT-M is the next digital service offering in INMARSAT's strategy. Standard-M is a Demand Assigned Multiple Access (DAMA) SCPC digital telephony service that includes options for facsimile relay, and 2400 bps data. The voice coder is a 4.2 Kbps Improved Multi-Band Excitation (IMBE) algorithm that with FEC bits in the coder has a aggregate rate of 6.4 Kbps. This VoCoder has exceptional quality speech at low rates and can operate down to 10^{-2} Bit Error Rate. Although the Inm-M is not meant to be a direct substitute for the Inm-A, many LMSS users as well as vessels between 15 to 20 meters in length will find that the Inm-M will cater to their needs. The Inm-M will be introduced in early-to-mid 1992 and full four ocean region service will be available in mid-1993. The INMARSAT-M access control and signalling design is based on that adopted for INMARSAT-B. The target price of the "M" is $15-20,000 depending upon options and Land vs. Maritime version. Since some users will want SafteyNet or Telex services, INMARSAT believes that the combination of M&C will also be popular and at $22-28,000 many of the new ship builds will choose this configuration over Inm-A at $35,000.

INMARSAT-B is the direct replacement for Inm-A. This digital terminal is intended to be shipboard-only and consists of a 16 Kbps Adaptive Predictive voice coder. Telex,



S-A Model 9806 TerraStar-C Suitcase Portable MES
Figure 3

Group-3 Fax, and data up to 9.6 Kbps are also standard features of the "B". The projected price for the Inm-B is $40,000. To allow existing users of Inm-A terminals to fully utilize their investment, INMARSAT has restated its policy to support Inm-A services until at least 2005. INMARSAT will allow new commissionings of Inm-A SESs for a minimum of three years after the introduction of INMARSAT-M/B (i.e., until 1995/1996 at least).

Regional Systems

The third stage of mobile satcoms development began with the idea that regional mobile services could be introduced. In the mid-1980's it became apparent that earth terminal developments in digital and RF technologies for Fixed Service Satellite (FSS) earth stations could be utilized in Mobile Satellite Services (MSS). Geostar Corporation found a market for Radio Determination Satellite Services (RDSS) using L- and S-band spectrum by providing position location information to US trucking and transportation operators. Qualcomm soon followed suit but utilized Ku-band. These two market entries marked the watershed for INMARSAT's MSS monopoly: Regional systems were feasible and users accepted them. A series of failed spacecraft launches and equipment problems eventually forced Geostar into bankruptcy in mid-1991. Qualcomm remains and is growing very rapidly with now over 14,000 vehicles equipped with RDSS and low-speed messaging mobile earth stations.

The national/regional systems that are planned for the near future are:

-AMSC (USA)
-TMI (Canada)
-AUSSAT (Australia)

All of these separate systems have loosely standardized on the INMARSAT terminal specifications. All use the Digital Voice

Systems, Inc. 6.4 Kbps codec for the low-cost telephony MES and all have allowed for Inm-C type services. These forward thinking developments allow manufacturers to have economies of scale thus passing on cost savings to the users in the form of lower MES prices. It is thought that the voice-only MES could be as low as $3,500 by the year 2000.

One other separate system to be considered is the Soviet MSS. The Soviet Union certainly has a great need for land mobile satellite services. Currently, there are two L-Band satellites in orbit providing service to the Moryasputnik user base of primarily SESs. Moryasputnik is a member of INMARSAT and a homogenization of services and satellites may be a forthcoming development.

Future Developments

What is next for the mobile satellite industry? The direction seems to be in the direction of Motorola's bold 77 Low Earth Orbit (LEO) "Iridium" satellite constellation for personal telephone communications. Another proposal is the ORBCOMM system from Orbital Sciences, Inc. that uses low-cost hand-held messaging terminals. Given that the technology of satellite-to-satellite links, on-board switching, and "upside down" cellular hand-off exists, we may see operational LEO satellite systems by the turn of the century.

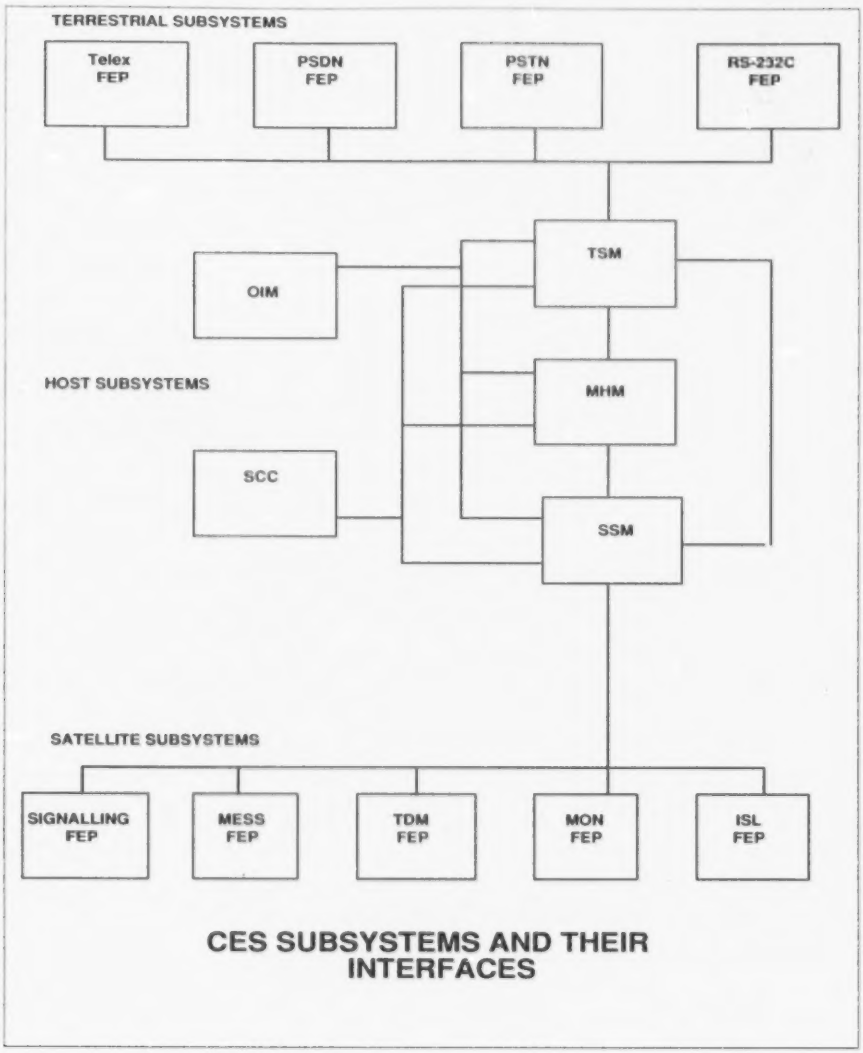
S-A Mobile Earth Station Systems

Scientific-Atlanta's pioneering involvement in mobile satcoms has now come full circle. S-A is again leading the world's development in INMARSAT digital telephony MESs and is investing large sums of research and development dollars into these new digital services. S-A's **MariStar**, **TerraStar** and **AeroStar** product lines are the most complete of any MES equipment provider. Additionally, Scientific-Atlanta can provide the complete, turnkey Land Earth Stations needed for the new C, M, and B digital services.

S-A's product line categories are delineated by their application. The shipboard (or maritime) earth stations are called MariStar. The TerraStar terminals are used for land mobile applications such as transportation (trucking, rail, etc.). Finally, S-A's AeroStar products are designed for commercial and general aviation aircraft applications. Table 1 shows the current Scientific-Atlanta digital MES product offerings.

Category	Class	Model No.	Description
MariStar	C	9801	Data-only SES (GPS option)
MariStar	M	9821	Voice, Fax, Data SES (GPS option)
TerraStar	A	9811	Suitcase Portable Inm-A
TerraStar	C	9805	Land mobile Inm-C (GPS option)
TerraStar	C	9806	Suitcase Portable Inm-C
TerraStar	M	9831	Land mobile Inm-M (GPS option)
AeroStar	C	9881	Air mobile Inm-C, doppler buffer (GPS option)

Scientific-Atlanta Digital MES Products
Table 1



CES SUBSYSTEMS AND THEIR INTERFACES

The LES systems from Scientific-Atlanta are designed for high reliability and flexibility. The architecture of the digital LES is one that allows an operator to start with Inm-C services, upgrade in a year or so to M, then as Inm-B comes on line, only channel units and additional procession need to added. Each subsystem is connected by two-zone, fault-tolerant DEC VAXft 3000 mini-computers, three 381 Mbyte disc drives, a 290Mbyte cartridge tape drive, and a dual (redundant) IEEE 803.2 Ethernet bus connecting each channel unit and Front-End Processors (FEP). FEPs serve each type of channel on the satellite side as well as each possible public (or private) network connection on the terrestrial side. Additionally there are dedicated FEPs for Interstation and Network Operations Center Signalling Links.

Each category of S-A's MESs are further subdivided into classes. The class correspond to INMARSAT's system definitions. These broadly define the communications capabilities available to the user of the MES. Lastly, the Model number is Scientific-Atlanta's generic classification of a single MES. However, each MES can be fitted with several options so there are dash and letter configurations after the model number that define the precise MES. Figure 3 shows the Scientific-Atlanta TerraStar-C Suitcase Portable MES.

In summary, mobile satellite communications has had a strong history of growth and innovation. A bright future lies ahead for INMARSAT and the regional mobilesat operators. New, low-cost digital MESs and LESs are available now from Scientific-Atlanta; the pioneer in mobile satellite communications.

Information Infrastructure

Pekka Tarjanne, Secretary-General
International Telecommunication Union
Geneva, Switzerland

Abstract

Today, the challenge in implementing and evolving telecommunications is being treated in very different terms. Telecommunications is increasingly being approached in the larger and much broader context of information infrastructure and economic growth. Getting that infrastructure into place and maximizing national and regional economic growth are the basic objectives; and how it is done is becoming secondary. This is resulting in the removal of barriers to competitive entry into telecommunication facilities and provisioning markets on a global scale, and opening the floodgates to infrastructure development.

What does this emerging infrastructure look like? While the details are not clear, the general form is. At the lowest layers, there are ever more numerous kinds of terrestrial and satellite facilities which provide cheap basic digital pipes to every corner of the world - a kind of newly emerging "global backplane." This backplane then supports the real innovation - the innumerable webs of networks and applications for every sector of business and society - the application communities. These communities, who have the ability to take the information tools and use them to meet their needs are a particularly critical part of infrastructure today, and providing them with low-cost tools is a necessary part of infrastructure. And lastly there is the need for new regulatory regimes that allow market-open competitive entry into the marketplace at national, regional and global levels, and that maintain effective competition.

The result should spur continued innovation and growth in economic, social and individual terms without parallel in human experience.

I would like to weave together many developments taking place today - just as you have done in your agenda for the Conference - and concentrate on a few "cosmic" developments: namely that telecommunication itself is being treated in fundamentally different ways and that new kinds of global information infrastructures are emerging.

Telecommunication: fundamentally different treatment

In 1991 - like the past few years - we witnessed profound change. Indeed, when we reflect on the evolution of the U.S.S.R. into the Commonwealth of Independent States, or the potential for a meaningful peace process in the Middle East, or the worldwide shifts toward more robust competitive economic systems, telecommunications developments seem to pale into insignificance. Even the continuing attempts taking place to surmount potential trade barriers in the GATT, and bring about a GNS, has the potential for profoundly affecting the global economy.

Telecommunications, however, are not entirely isolated from all these developments. Most people realize that telecommunications have played a significant role in bringing about these changes. And on the other side of the coin, telecommunications are being irreversibly affected by them as well. For example, at a *Financial Times* telecommunications conference a few weeks ago, one of the speakers noted that between 1990 and 1995, the number of telephone exchange lines operated by private companies worldwide will shift from 50 percent to 80 percent. During the past few years, we have witnessed most telecommunications making the shift from a rigid government monopoly offering to the business of competitive enterprise.

This does not mean, on the other hand, that government is no longer interested in the development and evolution of telecommunications. Certainly the amount of regulatory oversight necessary to assure fair, competitive playing fields has not diminished. In addition, the role of government in funding critically important infrastructure was certainly underscored when the Gore Bill was adopted in the closing days of the last U.S. Congress to fund the development of an entirely new generation of "gigabit networking" as well as the use of the Internet as a universal collaborative "knowledge" fabric. What this all means is that the role of governments - if not intergovernmental cooperation - is in the process of rapid change in the telecommunications field.

Of course, technology also continues to play a major part in this transition. One of our keynote speakers at the Telecom-91 Regulatory Symposium pointed out that the dramatic changes in transmission technologies have brought us many new networks all over the world. People have been able to build entirely new "instant networks." It has enabled the instant digitalization of long-haul networks.

Even more amazing is that none of this shows any sign of stopping. The speed that fiber is capable of is dou-

bling every year. What does this mean to regulation and competition in the business? It's not going to become a free resource. But it will become independent of distance - and eventually almost independent of bandwidth. Increasingly, the cost will be in access, administration and billing, not the technology. As a result, one of the highest profile developments in the ITU today involves the attempts to move the price of international communication more in line with real costs, and to do so on a basis that doesn't discriminate among countries.

Along similar, but perhaps even more unexpected lines, the cost of building intelligent devices using computers continues to plummet. This continues to change the entire architecture of telecommunications. For example, one of the more significant issues in the U.S. today is access to "dark fiber" so that more of the ultimate capacity of the fiber can be used directly.

As this trend continues, more and more value-added processing is moving external to the networks. In many respects, the integrated circuit revolution is sucking the intelligence out of the networks, just as the Personal Computer has sucked much of the intelligence out of mainframes and put it on the desk. This allows for all kinds of new network capabilities to be put into place very quickly without having to wait for any kind of central coordination or control. It is also resulting in enormous investments in private networking infrastructure - especially in Local and Wide Area Networks - whose massive growth over the next few years in the telecommunications field will only be matched by mobile communications networks and services.

It is not surprising then that telecommunications is being approached in the larger and much broader context of information infrastructure and economic growth. Getting that infrastructure into place and maximizing national and regional economic growth are the basic objectives; and how it is done is becoming secondary. This is resulting in the removal of barriers to competitive entry into telecommunication facilities and provisioning markets on a global scale. Through a variety of means - ranging from competitive global end-to-end provisioning to innumerable joint ventures - telecommunications provisioning, access and use have become a competitive global business playing by *de facto* trade-in-services rules, even if a GATT-GNS agreement pertaining to telecommunications does not yet exist.

Last year, for example, one of the more notable achievements at the international level was a revised CCITT Recommendation D.1 on the significantly liberalized provisions on the availability and use of private leased lines. Some of the participants in both the CCITT and the GATT discussions were the same people who, with surprising ease, simply made the transition from one international body to another to further the evolution of the same language and norms, and then several months later at Telecom-91 reflected on the whole experience.

In the process of dropping the barriers to entry into telecommunications provisioning, the floodgates to information infrastructure development are being opened. As we embark upon 1992 and move further into a remarkable new decade of globalization, "dropping the barriers" in so many ways seems like a permanent and productive trend.

It seems to me, however, that a great deal of work remains to be done. For example, the differences in open network approaches of different nations and regions portend a major need to harmonize these approaches in the coming years.

In addition, the increasing tendency to proceed with standards making activities in more diverse industrial, regional, and national forums will enhance the importance of timely, easy, and fully open access to standards and standards making processes. The open "networking" of standards that was so successfully demonstrated by the ITU late last year in making CCITT Recommendations available on servers throughout the world, needs to be replicated for all standards making institutions.

The Shape of the Infrastructure

It is fair to ask - or at least to explore - what this emerging information infrastructure may look like? While the details are not clear, we know courtesy of Peter Huber what the general form is - geodesic. However, unlike the geodesic dome, but perhaps more like Unix Kernels, this structure consists of onion-like layers.

At the lowest layers, there are ever more numerous kinds of terrestrial and satellite facilities which provide cheap basic digital pipes to every corner of the world - a kind of newly emerging "global backplane."

However, I do believe that portions of this backplane will have significant built-in intelligence - typified by the Intelligent Network efforts now underway in the CCITT and other places around the world. The quandary confronting us pointed out by a recent commentator who noted that "although we all want access to the whole world from wherever we are, we don't want the whole world to have access to us." It is going to take a certain amount of our own intelligence, combined with a lot of network intelligence to sort out these problems and provide the right kind of connectivity or "non-connectivity" through various technical and social filters.

It will be this backplane that supports the real innovation - the innumerable dynamic webs of networks and applications for every sector of business and society - the application communities. In the past, these communities were called "users." Somehow this doesn't seem adequate today. Maybe the term "customer" is better - but still fails to convey the degree of interactive control provided. Maybe the right term hasn't yet been invented.

In any case, these communities have the ability to take the information tools and employ them to meet their needs. They are a particularly critical part of infrastructure today, and providing them with low-cost tools is a necessary part of information infrastructure.

In the future, I believe this aspect of information infrastructure will receive increasing attention. Certainly the famous U.S. National Research and Educational Network initiative and its counterparts throughout the world, are significant attempts to get beyond just having the tools available. The problem is that the tools have become available faster than our human social systems can make use of them. As a result, we frequently have large segments of populations, professions and institutions in every country - from the most affluent to the poorest - which can become more efficient and effective, by using the available tools and those who cannot....or will not.

Where is the nearest accessible EMail terminal? How many people at this meeting effectively collaborate through electronic networks? Why can't those who are unable to come to this meeting access the papers electronically? Why can't I easily use my mobile phone or laptop PC modem here at the meeting? I think the answers to these questions go to the heart of a significant problem we are facing today. The tools are there, but changing people's cultures is not so easy. But perhaps next year, we will be able to register for PTC-93 electronically!

* * *

Although there may be impediments, and the precise implementations are unclear, the general directions toward an emerging information infrastructure are rather apparent. The genuinely exciting news is that the result should spur continued innovation and growth in economic, social and individual terms without parallel in human experience.

PTC' 92

14TH PACIFIC TELECOMMUNICATIONS CONFERENCE

SHERATON WAIKIKI HOTEL, HONOLULU, HAWAII

JANUARY 12 - 15, 1992

ADDRESS BY HONOURABLE DATO' SERI S. SAMY VELLU, MINISTER OF ENERGY, TELECOMMUNICATIONS AND POSTS, MALAYSIA

LADIES AND GENTLEMEN,

I AM INDEED GREATLY HONOURED AND PRIVILEGED TO HAVE BEEN INVITED TO ADDRESS THIS DISTINGUISHED GATHERING OF POLICY MAKERS AND PROFESSIONALS OF THE TELECOMMUNICATIONS INDUSTRY IN THE PACIFIC HEMISPHERE.

I MUST ALSO THANK THE ORGANIZERS OF THE CONFERENCE FOR THE OPPORTUNITY GIVEN TO ME AND MY DELEGATION TO PARTICIPATE IN THIS MEETING WHICH IS RECOGNIZED AS THE PREMIER CONFERENCE COVERING THE LATEST DEVELOPMENTS AND PROPOSALS IN TELECOMMUNICATION SYSTEMS AND SERVICES FOR THE PACIFIC REGION.

LADIES AND GENTLEMEN,

IT IS NEEDLESS TO SAY THAT EFFECTIVE AND RELIABLE TELECOMMUNICATIONS IS A PREREQUISITE FOR ECONOMIC DEVELOPMENT, GLOBAL TRADE AND FOREIGN INVESTMENT. THIS IS VERY EVIDENT IN MY COUNTRY, MALAYSIA, WHERE EXPANDING TELECOMMUNICATION CAPABILITIES HAVE GONE HAND-IN-HAND WITH RAPID ECONOMIC GROWTH.

A COHERENT GOVERNMENT POLICY ON PRIVATIZATION HAS PROVIDED THE IMPETUS CRUCIAL TO THE DEVELOPMENT OF TELECOMMUNICATIONS IN MALAYSIA. THE MALAYSIAN TELECOMMUNICATIONS INDUSTRY TODAY IS THE RESULT OF A LIBERALIZATION PROCESS THAT HAS LEFT AN INDELIBLE MARK ON THE STRUCTURE OF THE INDUSTRY WHICH CAN BE TRACED BACK TO 1983 WHEN THE GOVERNMENT DECIDED TO OPEN UP PAGING OPERATIONS TO

LOCAL LICENSEES. THE TURNING POINT CAME IN 1987 WHEN THE TELECOMMUNICATIONS DEPARTMENT WAS CORPORATIZED CREATING TELEKOM MALAYSIA, THE FIRST GOVERNMENT UTILITY TO BE TRANSFORMED UNDER A PUBLICLY ANNOUNCED PRIVATIZATION PLAN.

TELEKOM MALAYSIA OPERATES AN INTEGRATED NETWORK FOR THE RESERVED TELEPHONE, LEASED LINE, TELEX, PACKET SWITCHED AND CIRCUIT SWITCHED SERVICES. THE NATIONWIDE TELEPHONE SERVICE FOR THE PRESENT 1.6 MILLION CUSTOMERS IS PROVIDED BY A NETWORK OF 562 TELEPHONE EXCHANGES, OF WHICH 315 ARE DIGITAL. THE TRUNK MICROWAVE NETWORK CONSISTS OF BOTH ANALOGUE AND DIGITAL SYSTEMS. SOME 407 MICROWAVE STATIONS MAKE UP THE ANALOGUE MICROWAVE TRUNK NETWORK, WHILE 235 STATIONS MAKE UP THE RECENTLY COMMISSIONED DOMESTIC DIGITAL MICROWAVE NETWORK. FIBRE OPTICS HAVE ALREADY BEGUN TO BE LAID IN SELECTED SHORT-HAUL INTRA-CITY ROUTES, PARTICULARLY IN THE BUSINESS AND FINANCIAL CENTRES. PLANS ARE AFOOT TO EXPAND THE USE OF FIBRE OPTICS IN BOTH THE OVERLAND AND SUBMARINE TRUNK NETWORK. THE FIRST OPTICAL FIBRE SUBMARINE CABLE TO BE OPERATIONAL IN THE ASEAN REGION LINKING KUANTAN AND KOTA KINABALU PROVIDES A QUANTUM LEAP IN QUALITY AND CAPACITY. THIS COMMISSIONING WAS CRUCIAL TO BRINGING THE VISION OF A NATIONWIDE INTEGRATED DIGITAL NETWORK CLOSER TO REALITY. THE INTERNATIONAL GATEWAY SWITCH AT KUANTAN HAS HELPED THE GROWTH OF INTERNATIONAL TRAFFIC TO AND FROM MALAYSIA.

WITH A GROWTH RATE OF 14 PER CENT IN THE TELEPHONE SERVICE IN 1990, THERE IS SUFFICIENT MOMENTUM AND POTENTIAL IN THE MARKET FOR THIS LEVEL OF GROWTH TO BE MAINTAINED DOUBLING

THE SUBSCRIBER BASE TO 3.2 MILLION BY 1995. THE OPPORTUNITIES FOR MARKET DEVELOPMENT ARE IMMENSE, AS THE MARKET IS CHARACTERIZED BY HIGH GROWTH AND LOW PENETRATION LEVELS WHICH HAS ACHIEVED A FIGURE OF 9 ACCESS LINES PER 100 POPULATION BY END-1990 AND THIS IS EXPECTED TO RISE TO 15 BY 1995. WHILE THIS IS THE GROWTH SCENARIO PROJECTED DOMESTICALLY, ITS IMPACT ON INTERNATIONAL TELEPHONE TRAFFIC IS EXPECTED TO BE TREMENDOUS. STEADY GROWTH IN THE REGION OF 35 PER CENT HAS BEEN THE ORDER OF THE DAY IN THE LAST FOUR YEARS, THE TOTAL VOLUME BEING 181 MILLION MINUTES LAST YEAR. TO MEET THESE GROWTH SCENARIOS, HEAVY INVESTMENTS WILL BE CHANNELLED INTO THE NETWORK TO MEET BOTH MARKET GROWTH AND ENHANCE NETWORK QUALITY AND US$1.2 BILLION IS EXPECTED TO BE SPENT ON CABLE, SWITCHING AND TRANSMISSION NETWORKS. INTERNATIONAL COMMUNICATIONS WILL ALSO BE ENHANCED IN THE NEAR FUTURE WITH THE INSTALLATION OF TWO ADDITIONAL INTERNATIONAL GATEWAYS TO BE LOCATED IN KUALA LUMPUR.

THE GOVERNMENT AIMS TO ENDOW THE NATION WITH A SYSTEM OF TELECOMMUNICATIONS COMPARABLE WITH THAT OF DEVELOPED COUNTRIES BY THE END OF THE DECADE. IN ANTICIPATION OF NEW AND INTELLIGENT SERVICES THAT WILL BE IN DEMAND, THE NETWORK IS BEING PREPARED FOR THE INTRODUCTION OF COMMON CHANNEL SIGNALLING NO. 7. CCS 7 PLANNING WILL BE INCORPORATED INTO REGULAR EXPANSION AND DIGITALIZATION PROGRAMMES WHERE FULL DIGITALIZATION OF THE NETWORK IS EXPECTED TO BE ACHIEVED BY 2000.

VARIOUS INITIATIVES HAVE BEEN PLANNED AND MADE

OPERATIONAL TO ACHIEVE EXCELLENCE IN CUSTOMER SERVICE AND NETWORK QUALITY. AN AUTOMATED CUSTOMER COMPLAINTS SYSTEM WHICH SPEEDS UP SERVICE RESTORATION WAS ESTABLISHED IN OCTOBER 1990. THE SYSTEMS FOR TESTING AND ADMINISTRATION FOR REPAIR SERVICES (STARS) WILL BE EXTENDED NATIONWIDE IN STAGES. FOR BUSINESS CUSTOMERS WHO USE DATA SERVICES AND LEASED LINES, SERVICE QUALITY WILL BE CENTRALLY MONITORED AND MANAGED USING THE MANAGED LEASED CIRCUIT NETWORK (MLCN). THE SYSTEM WILL PROVIDE CENTRAL SUPERVISION AND CONTROL, ALLOW REMOTE SET-UP, PROVIDE AUTOMATIC RE-ROUTING IN THE EVENT OF CIRCUIT FAILURE, PROVIDE PART-TIME DIGITAL LEASED CIRCUITS, AND OFFER FACILITIES FOR DISASTER RECOVERY CENTRES. FOR OVERALL NETWORK QUALITY, A NETWORK MANAGEMENT SYSTEM (NMS) IS ALSO BEING DESIGNED TO ENSURE EFFICIENT OPERATION THROUGH REAL-TIME TRAFFIC MANAGEMENT.

THE RANGE OF SERVICES OFFERED IS VARIED, COVERING SPECIALIZED AND BUREAU SERVICES, DATA COMMUNICATIONS, RADIO AND MOBILE SERVICES, AND VARIOUS INTERNATIONAL, VOICE, TEXT AND VALUE-ADDED SERVICES. AMONGST THE INTERNATIONAL SERVICES OFFERED ARE THE INTELSAT BUSINESS SERVICE (IBS), INMARSAT, VOICECASTS AND TELECASTS. APART FROM THESE THE NATIONAL PACKET-SWITCHED SERVICE, MAYPAC AND OTHER LEASED SERVICES SUCH AS DIGITALINE ALSO OFFER HIGH SPEED DATA CIRCUITS TO INTERNATIONAL DESTINATIONS. INTERNATIONAL DIRECT DIALLING (IDD) SERVICE IS AVAILABLE TO A TOTAL OF 178 DESTINATIONS WORLDWIDE. VARIOUS NEW SERVICES SUCH AS CENTREX, ADVANCED 800, VIDEO CONFERENCING AND ISDN FACILITIES ARE BEING MADE AVAILABLE. THESE INTELLIGENT NETWORK SERVICES WILL ALLOW

USERS TO CUSTOMIZE SERVICES DIRECTLY THROUGH THEIR TERMINALS. THESE SERVICES PROVIDED SUPPORT FOR THE PROGRESSION OF THE ECONOMY TO ONE BASED ON MANUFACTURING AND SERVICES. THROUGH THESE SERVICES, GREATER DEPTH IS ADDED TO INTERNATIONAL OPERATIONS LOCATED IN MALAYSIA, PARTICULARLY IN THE FINANCE AND MANUFACTURING AREAS. CUSTOMERS HAVE A VARIETY OF SERVICES TO SUBSCRIBE TO, ECONOMIZING THEIR RESOURCES AND OPTIMIZING BENEFIT IN THE PROCESS. FOR OTHERS, SOME OF THESE SERVICES PROVIDE THE COMPETITIVE EDGE SOUGHT IN THEIR LINE OF BUSINESS.

THE GROWTH TREND OF MOBILE COMMUNICATIONS WILL ACCELERATE IN THE 1990S AS USERS ARE INCREASINGLY FLEXIBLE AND MOBILE IN THEIR BUSINESS ACTIVITIES AND LIFESTYLES. MOBILE COMMUNICATIONS WERE AVAILABLE TO THE MALAYSIAN PUBLIC IN 1964 WHEN PUBLIC CORRESPONDENCE NETWORK (PCN) WAS LAUNCHED. THIS WAS A RADIOTELEPHONE SERVICE THAT WAS AVAILABLE TO CUSTOMERS RESIDING WITHIN A 30 KM RADIUS OF KUALA LUMPUR. TODAY, WE HAVE 2 CELLULAR SYSTEMS WHICH ARE IN OPERATION, 3 ACTIVE TRUNK RADIO OPERATORS, 3 LICENSEES ON CT-2 DIGITAL CORDLESS AND SOME 20 OVER PAGING OPERATIONS. THERE IS A RANGE OF SERVICES AVAILABLE TO THE MALAYSIAN USER AND FINAL CHOICE IS DICTATED BY ONE'S OWN COMMUNICATION NEEDS IN TERMS OF FUNCTIONALITIES, SECURITY AND PRIVACY OF SPEECH, QUALITY OF SERVICE AND THE PRICE ONE IS WILLING TO PAY FOR.

APART FROM ALL THIS SOPHISTICATED NEW TECHNOLOGY IN THE FIELD OF TELECOMMUNICATIONS, THERE IS THIS IMPORTANT ASPECT OF REGULATION.

LADIES AND GENTLEMEN,

THE EIGHTIES WILL BE REMEMBERED AS A DECADE OF REMARKABLE CHANGES IN THE WORLD OF TELECOMMUNICATIONS. THE CHANGES RESULTED FROM THE IMPLEMENTATION OF A NEW POLITICAL PHILOSOPHY AT A TIME WHEN TECHNOLOGY WAS DEVELOPING RAPIDLY. THE PIVOTAL EVENTS WERE THE PRIVATIZATION OF THE PTT'S IN VARIOUS COUNTRIES, INCLUDING MALAYSIA. AFTER THE CORPORATIZATION AND EVENTUAL PRIVATIZATION OF THE PTT IN MALAYSIA, THE GOVERNMENT RETAINED THE REGULATOR FUNCTIONS UNDER THE DEPARTMENT OF TELECOMMUNICATIONS. TO THIS END, LIBERALIZATION AND PRIVATIZATION RAISE ISSUES OF THE MANAGEMENT OF CHANGE. EACH NATION HAS A DIFFERENT SET OF VALUES, CIRCUMSTANCES AND PRIORITIES THAT DICTATE THE NATURE OF THE CHANGES AND THE RATE AT WHICH THEY SHOULD OCCUR. THESE CHANGES MUST BE MANAGED AND REGULATED IN A TIMELY MANNER.

THERE HAVE BEEN THREE CLOSELY INTER-RELATED LINES OF DEVELOPMENT:-

1. *THE FUSION OF TELECOMMUNICATIONS AND COMPUTERS RESULTING IN AN ARRAY OF INFORMATION TECHNOLOGIES AND NEW SERVICES;*

2. *LIBERALIZED, COMPETITIVE ENVIRONMENT SPEEDS UP THE RATE OF CHANGE AND TENDS TO IMPROVE THE PERFORMANCE OF THE PRIVATIZED MONOPOLY;*

3. *USERS ARE DEMANDING FOR THE BEST SERVICES AND AT*

COMPETITIVE PRICES.

IN MALAYSIA, THE TELECOMMUNICATIONS ACT SETS THE FRAMEWORK FOR THE REGULATION OF TELECOMMUNICATIONS IN THE COUNTRY. IN THE FIVE YEARS THAT HAS PASSED, MUCH HAS HAPPENED TO DEMONSTRATE THAT THE EXPECTATIONS OF THE PRIVATIZED COMPANY AND THE GOVERNMENT DIFFER IN MANY WAYS AND IN CERTAIN RESPECTS THESE DIFFERENCES ARE OF A FUNDAMENTAL NATURE. I WOULD THEREFORE RECOMMEND TO ANY COUNTRY ON THE VERGE OF PRIVATIZATION TO MAP OUT CLEARLY THE POLICIES APPLICABLE IN THE PRIVATIZED ENVIRONMENT AND THE DIRECTION FOR THE PRIVATIZED COMPANY IN ORDER TO AVOID THESE DIFFERENCES.

THERE IS A NEED NOW TO SPELL OUT THE FUTURE COMPETITION POLICY TO TAKE THE TELECOMMUNICATIONS INDUSTRY ALL THE WAY TO 2020 WHEN WE PLANNED TO BE INDUSTRIALIZED. IN CHARTING FUTURE COMPETITION POLICY FOR THE BASIC SERVICES THE FACTORS OF:

1. THE SIZE OF THE PRESENT NETWORK;

2. THE TECHNOLOGIES THAT ARE BEING DEVELOPED;

3. ECONOMIES OF SCALE;

4. DUPLICATIONS OF RESOURCES AND NETWORKS.

MUST BE TAKEN INTO CONSIDERATION. AFTER REVIEWING THE ABOVE, THE MOST VIABLE FORM OF COMPETITION WOULD BE TO USE

THE WIRELESS TECHNOLOGIES TO COMPETE AGAINST THE WIRED NETWORK.

FOR THE NON-BASIC OR NON RESERVED SERVICES, INCLUDING VALUE ADDED SERVICES, THE POLICY WILL BE TO PROMOTE COMPETITION AND TO REMOVE BARRIERS TO MARKET ENTRY IN ORDER TO INCREASE THE VARIETY AND QUALITY OF SERVICES AVAILABLE TO THE CONSUMERS. THESE SERVICES WILL PROMOTE THE FORMATION OF THE "INFORMATION SOCIETY" AND ALSO PROVIDE A COMPETITIVE EDGE TO OUR INDUSTRIES. THERE IS ALSO A NEED TO DEFINE THE PRICE CONTROL MECHANISM ESPECIALLY FOR THE BASIC SERVICES. THE RATE OF RETURN MECHANISM AND THE PRICE CAP MECHANISM HAVE BEEN CONSIDERED AND THERE IS A LIKELIHOOD THAT THE LATTER WILL BE ADOPTED. PRICES ARE LINKED TO THE QUALITY OF SERVICES AND THEREFORE THERE IS A NEED TO MONITOR AND TO ENFORCE QUALITY OF SERVICE STANDARDS. QUESTIONS LIKE WHETHER THE MONOPOLY IS BEING RUN EFFICIENTLY AND AT WHAT RATE OF RETURN IS JUSTIFIABLE IN A MONOPOLISTIC ENVIRONMENT WILL HAVE TO BE ADDRESSED. THE FUNCTIONS OF THE REGULATORY BODY ALSO INCLUDES TECHNICAL REGULATIONS SUCH AS:-

1. *ESTABLISHMENT OF TELECOMMUNICATION STANDARDS AND THEIR ENFORCEMENT;*

2. *INTERCONNECTIONS BETWEEN NETWORKS; AND*

3. *INTERFACES AND CONNECTIVITY, NUMBERING SCHEME AND FUNDAMENTAL PLANS.*

TECHNICAL REGULATIONS HAVE BECOME INCREASINGLY COMPLEX AND THE MORE NETWORK LICENCES ARE ISSUED, THE GREATER WILL BE THE INTERCONNECTION COMPLEXITY. THE INTERCONNECTIONS BETWEEN NETWORKS HAVE TO BE PLANNED, REGULATED AND POLICIES FORMULATED IN ORDER TO ENSURE EFFICIENT CONNECTIVITY.

THE DEVELOPMENT OF RADIO COMMUNICATION BASED NETWORKS DURING THE LAST FEW YEARS HAS BEEN TREMENDOUS AND THE DEMAND FOR FREQUENCY SPECTRUM IS REACHING NEW HEIGHTS. END USERS LICENSING FOR RADIO COMMUNICATIONS APPARATUS HAS BEEN A MAJOR TASK ESPECIALLY AFTER PRIVATIZATION DUE TO THE HUGE INCREASE OF USERS. A VARIABLE FEE STRUCTURE MAY BE INTRODUCED, BASED ON THE SERVICE CAPACITY AND REVENUE PRODUCING CAPACITY OF THE FREQUENCY ASSIGNED AND THESE WILL BE ADDRESSED IN THE NEW RADIO COMMUNICATION REGULATIONS.

THE PROMOTION OF A LIBERALIZED, COMPETITIVE ENVIRONMENT WILL CERTAINLY SPEED UP THE RATE OF CHANGE. AS MANAGERS OF CHANGE WE HAVE TO ENSURE THAT THE CHANGE IS MANAGED FOR THE BENEFIT OF THE NATION AND I BELIEVE THAT OUR COUNTRY IS ONE OF THE NATIONS WHERE AFTER PRIVATIZATION, THERE WAS NO INCREASE IN TARIFFS. SOME MAY NOT BE HAPPY WITH OUR RATE OF CHANGE. BUT THE KNOWN DIFFICULTIES OF MANAGING CHANGE ARE THE BEST REASON FOR TAMPERING WITH THE HURRICANE OF LIBERALIZATION.

LADIES AND GENTLEMEN,

IN CONCLUSION, I WOULD LIKE TO THANK THE PACIFIC

TELECOMMUNICATIONS COUNCIL AGAIN FOR INVITING ME TO ADDRESS SUCH A HIGH POWERED GATHERING AND I HOPE THAT YOU WILL BE A CATALYST FOR ADVANCEMENT IN THE FIELD OF TELECOMMUNICATIONS NOT ONLY IN THE PACIFIC REGION BUT ALSO GLOBALLY.

THANK YOU.

Pacific Telecommunications Conference
January 1992, Honolulu

Telecommunications Environment in Hong Kong : Regulatory Framework, Market Access and Opportunities

Mr. Dominic S.W. Wong, JP,
Postmaster General and Telecommunications Authority
HONG KONG

Mr. Chairman, Distinguished Delegates, Ladies and Gentlemen,

I am pleased to be with you this morning in the beautiful city of Honolulu. The organisers of the 14th Pacific Telecommunications Conference have asked me to give a presentation on the telecommunications environment in Hong Kong. As the regulator, I am glad to share with you in a few moments some of our experience in the development of telecommunications in Hong Kong, the market opportunities that are currently available and our plans in the next few years.

Background

2. Before I go into this actual topic, let me give you a brief introduction of Hong Kong. We have a small land area of 1,075 square kilometres, and started off as a small fishing village 150 years ago. Because of our strategic location in the Far East, the existence of an excellent natural harbour, the presence of a hard-working labour force, our adaptability to changes and our free trade policy, Hong Kong soon acquired the status of an entrepot in the Orient. With the decline of the entrepot trade, we adapted quickly to this change and turned ourselves into a manufacturing centre of light consumer goods in the 1950's and the 1960's. In the last twenty odd years we continued to diversify and assumed prominence as an important commercial, financial and communications centre in the world. The availability of efficient domestic and international telecommunications systems contributed significantly to our success. The need to maintain a reliable and efficient telecommunications infrastructure is self-evident.

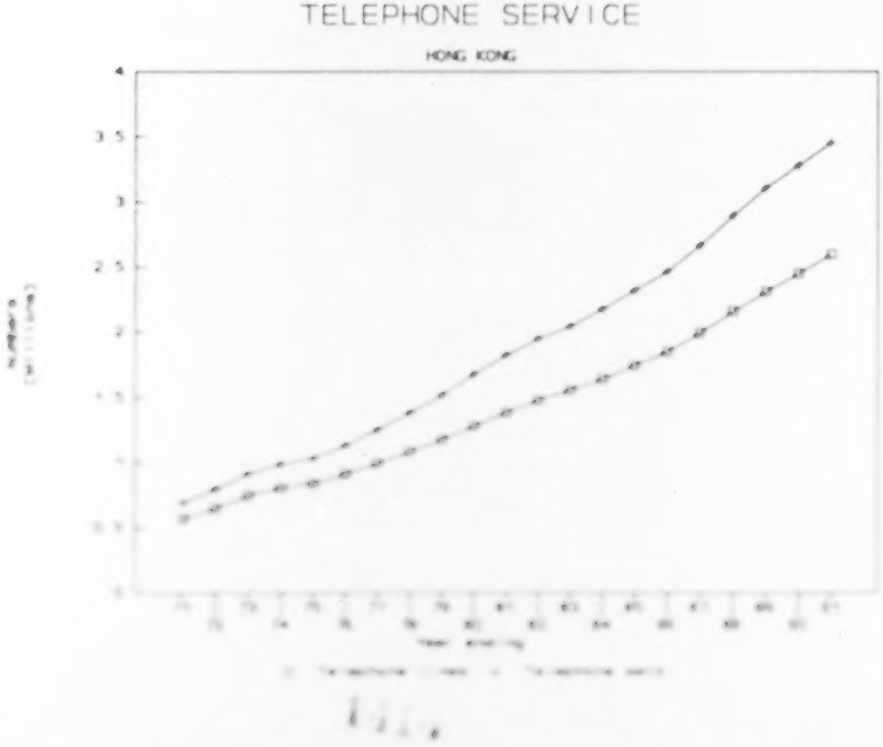
3. In 1990 our total turnover in telecommunications services was US$2 billion (1 billion = 1,000 million). The total export of electronics products was US$15 billion, of which about US$1.5 billion were telecom-

munications equipment. Our GDP per capita was US$12,000. We were the world's tenth largest trading economy, the busiest container port, the fourth busiest air cargo terminal, and the fifth leading financial centre with over 500 foreign banks and deposit taking companies. We had over 300 public listed companies with a market capitalisation of over US$100 billion. That in brief is the prosperous territory of Hong Kong.

Regulatory Environment

4. Such a vibrant market economy needs to be well supported by a good infrastructure. As far as telecommunications is concerned and unlike many countries, the Hong Kong Government is not directly involved in the construction of telecommunications networks or the provision of services in the territory. Instead we encourage private sector investments in public utilities and economic infrastructure, and private companies enjoy much freedom in carrying out their tasks with minimum government intervention. History has shown that our policy has borne fruit.

5. Against this background the first private telephone system was introduced in Hong Kong in 1877, only one year after its invention by Alexander Graham Bell in the United States. The first public telephone service started five years later. Although there were changes in company ownership, subsequent operators continued to operate as a monopoly. By the beginning of the 1980's the wireline telephone network became a comprehensive one and offered an efficient service. At present we have 3.4 million telephones, 2.6 million exchange lines and 130,000 facsimile lines. Over 90% of these lines are digitalised. These figures represent a high penetration rate of 59 telephone sets , 45 exchange lines and 2 facsimile



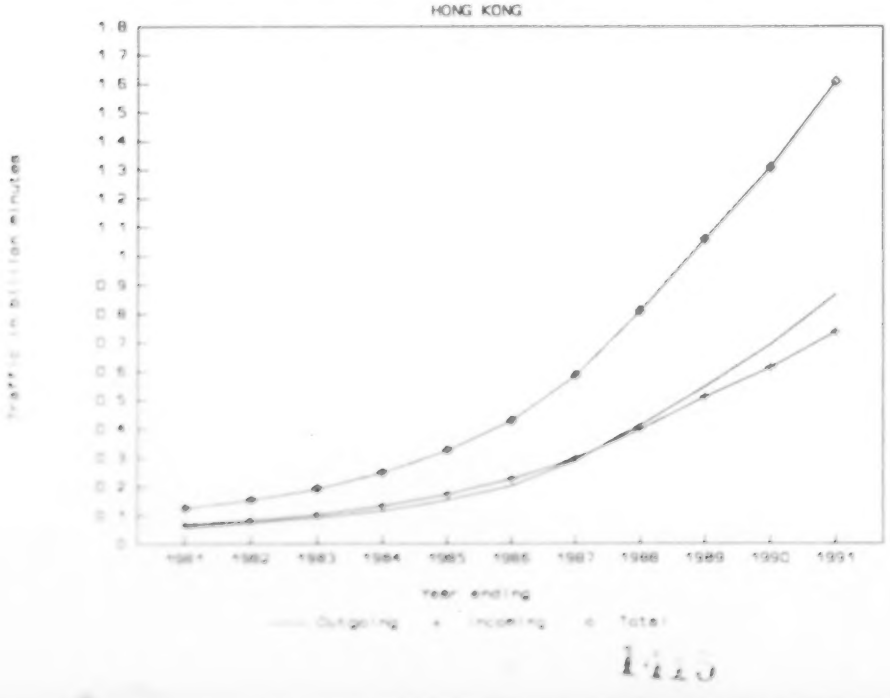
lines per 100 population. The Hong Kong Telephone Company's exclusive franchise for domestic telephone service expires in three and a half years time in June 1995. I know that there are eager eyes watching what the environment will be after that date. A decision will be taken soon.

6. Similar to the domestic telephone service, an exclusive right to supply and operate external telephone and telegraphic services was granted to Cable and Wireless Ltd. The company, recently re-named Hong Kong Telecom International, has been providing a very good service, making heavy capital investments and has succeeded in bringing its network and services to a world renowned standard. International telephone traffic reached 1,375 million minutes in the year ending March 1991, representing four hours for each person in Hong Kong and an increase of about 23% over the previous year. The company's exclusive licence runs another 15 years until 2006.

7. Hong Kong has come a long way under these monopoly arrangements for basic services. This approach has a clear advantage during the start up phase. By the beginning of the 1980's our two exclusive franchise holders together were able to provide comprehensive and efficient networks of domestic telephone and international telecommunications services, with continual updating in technology and improved quality of service to meet basic community needs. Services were widely available at relatively low prices.

8. With the basic telecommunications infrastructure thriving, we were then able in the past decade to embark on gradual deregulation and introduction of competition in other telecommunications services. The outcome is

INTERNATIONAL TELEPHONE TRAFFIC VOLUME



fabulous. Hong Kong benefits from the competitive supply of customer premises equipment (CPE). A wide range of equipment with different countries of origin and at reasonable prices are now available, and a vibrant equipment market has been created.

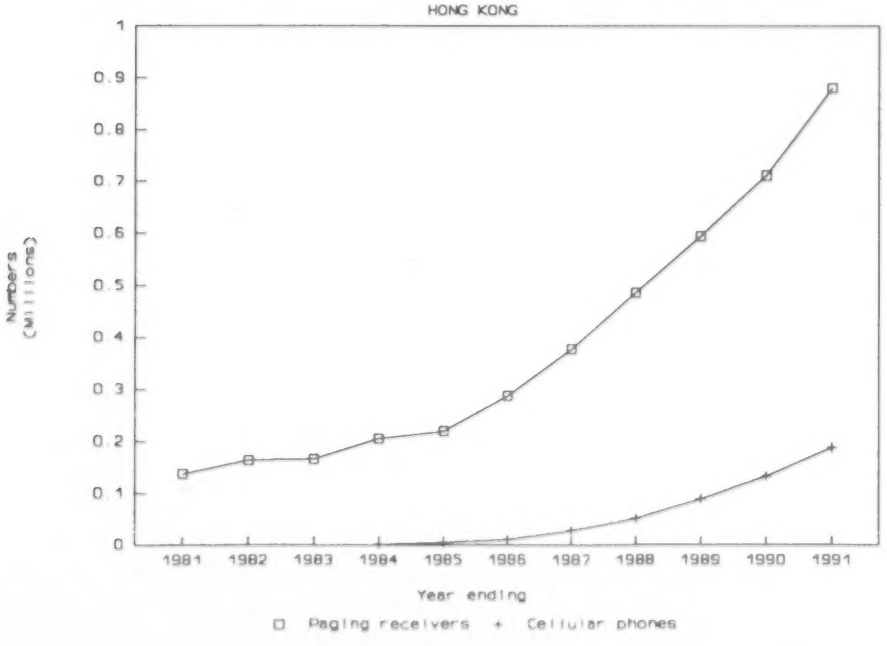
9. The first taste of competition has also created our success story in respect of mobile communications services. Legislation was made, permitting the provision of wireless telephone services and value added services both interconnectable with the public switched telephone network (PSTN) at a charge subject to control by the Government. The licensing regime is deliberately made simple and easy to administer, and centres around technical expertise, financial capability, management structure and quality of service.

10. Within this environment we have licensed four cellular telephone systems : one using the US AMPS and three using the European ETACS standards. At present the number of cellular phone users stands at 180,000, representing a penetration rate of 3% population. I am told that Hong Kong has the highest proportion of hand held portable phones in any sizable cellular phone market in the world.

11. We have also a very competitive radio paging market with over 30 operating companies. There are over 860,000 users, representing a penetration rate of 15% of population. Again this is the highest in the world.

12. Competition has given consumers wide choice, not just of operators but also of equipment. For example, many brands of cellular phones of varying capabilities are available. There are radio pagers that can display messages in English and Chinese; pagers in the size of a credit

PUBLIC RADIOCOMMUNICATION SERVICES



card or a wrist watch; paging services that allow private telephone lines to be answered by paging operators who act as secretaries 24 hours a day. More importantly, services are now available at reasonable prices. For example, the air-time charges are about US$25 a month for unlimited calls for radio paging services and about US$0.20 per minute for cellular phone services.

Overall Objective

13. As the Telecommunications Authority of Hong Kong, my objective is to foster a favourable environment for the growth of an adequate telecommunications infrastructure and to establish a stable regulatory framework for the provision of telecommunications services, whether they are provided on an exclusive or competitive basis. This, in turn, will bring benefits to users in the form of improvements in technology and efficiency.

Recent Developments

14. In the past year we continued to support the introduction of new and innovative services on a competitive basis, and to ensure that players in the field could compete on a fair and equitable basis. There were three important developments.

15. First, in January last year we reached an arrangement with the United States to introduce international value added network services (IVANS) using international private leased circuits between Hong Kong and the United States. Similar arrangements were made with the United Kingdom last June and with Japan last month. Services include enhanced facsimile and all forms of enhanced data communications. IVANS operators can therefore use IPLC's at the normal flat-rate tariffs, bringing corresponding benefits to consumers. Our experience has had positive results. We plan to make a similar arrangement with Australia soon and with other countries having similar interest.

16. Secondly, in March last year licences were granted to four operators to set up and operate territory-wide Telepoint Services using the Second Generation Cordless Telephone (CT2) technology. The licensees include major telecommunications players from the United States, the United Kingdom, Australia and Hong Kong. Construction of Telepoint networks is well underway, and we expect to have initial service within three months from now.

17. Thirdly, a licence was issued two months ago to a consortium (comprising the United States, Singapore and Hong Kong telecommunications operators) to construct and provide an international radio paging network and service using the frequency 931.9375 MHz. The service will be available in the middle of this year, and will initially cover the United States, Canada, Singapore and Hong Kong. It is expected to extend to other places in future. As there is only one common frequency designated at present, the network provider is required under the licence to make available the spare air-time for resale by other radio paging companies which therefore can also provide international radio paging services. Hence the market will remain competitive.

Market Access and Opportunities

18. I have spoken at length about the development of telecommunications services in Hong Kong and our regulatory policies. What about market access and opportunities?

19. In Hong Kong we have an open market economy. We practise and fully support the spirit of free trade without barriers, both in goods and in services. Being a full member of the GATT, we are fully committed to the GATT principles of allowing greater freedom for market access and the use of public telecommunications networks and services.

20. In the field of telecommunications in particular, we have a regulatory environment which permits market access to all forms competitive services. We adopt an open door policy for investments : thus there is no restriction on foreign ownership, and no requirement for local manufacturing or technology transfer. As I said earlier on, the licensing regime is deliberately made simple. Competitive services thriving under such environment include radio paging, trunk radio systems, cellular phones, international and local value added services, and CT2 Telepoints in the near future.

21. On the equipment supply side, you have heard that we have totally deregulated customer premises equipment and its connection into the public switched telephone network and other public telecommunications networks, subject of course to network compatibility. Recently we have retrieved the control of type approval and testing of equipment from the telephone network operator back to the Telecommunications Authority (which is myself). We believe that this will improve the transparency of the process and ensure fairness. Under the new procedure we can also accept type testing conducted by any accredited testing laboratory in Hong Kong or overseas. We will also consider conferring accreditation on manufacturers themselves if they have the relevant testing facilities and expertise to test the equipment to our specifications. Needless to say, our specifications are not onerous and are simply minimum requirements to ensure network integrity and compatibility. (A booklet on the new procedure is available.)

22. As regards IVANS and domestic value added services, the same simple licensing procedure applies. The criteria are published in a guidance note for applicants, and are merely requirements to ensure technical competence, service quality, fair competition and protection of consumer interests. A Public Non-Exclusive Telecommunications Service (PNETS) Licence can be issued within a fortnight.

Future Opportunities

23. What about the future? The telecommunications investment opportunities in Hong Kong are by no means finite. Some of you may recall that two years ago we licensed a company to provide a territory-wide cable television service in Hong Kong. Regrettably, owing to problems within the company it decided to withdraw from the project. We are still keen to have cable or subscription television in Hong Kong. We plan to invite applications again within six months. Even now, there are keen candidates

looming around the horizon, despite the availability of a wide range of satellite television programmes in Hong Kong as a result of our open sky policy. The successful bidder may, if it wishes, also apply to the Telecommunications Authority to operate telecommunications services.

24. As regards public cellular phone services, the existing networks (based on the analogue technology) will become saturated in about a year's time. We in Hong Kong have been monitoring the development of digital technology in Europe and the United States, and are satisfied that both the pan-European GSM standard and the United States Digital AMPS standard should be introduced in Hong Kong as from 1993. Naturally we have to bear in mind the contribution and achievement of the three existing operators on the one hand, and the desirability of encouraging further competition by admitting new players on the other. Licensing arrangements should be finalised within a few weeks, and I expect to make a public announcement on this subject very soon.

25. As regards the basic telecommunications services, the exclusive licence granted to Hong Kong Telecom International for the provision of public external basic telecommunications services will not expire until the year 2006. It is therefore too early to consider what should be done after that date.

26. The exclusive franchise for the operation of domestic telephone service will expire in June 1995. We are now undertaking a policy review to determine what the regulatory environment should be after that date. This is an exciting subject. We will draw on our own experience in recent years and take careful note of developments in other advanced economies. I believe that we will soon be able to make an announcement of our future policy - one which I hope will be encouraging.

Conclusion

27. Let me now sum up for you. In Hong Kong we adopt a liberal policy on the supply of telecommunications equipment and the provision of telecommunications services, except for the basic services where one exclusive franchise is due to expire in 3.5 years time and the other exclusive licence will remain for some time. We have no foreign ownership restrictions. We welcome foreign investments. As described earlier, there are ample opportunities opening up in the field of telecommunications in the near future. Hong Kong has the advantages of administrative efficiency, political stability and economic prosperity. As the Telecommunications Authority of Hong Kong, I welcome new business initiatives and participation as these will ensure a continuing vibrant market in Hong Kong, with the latest technology for end users and a wide variety of choice for consumers.

Thank you.
